Besides ordinary plant-constituents, Nectandra bark contains a number of alkaloids, and the wood contains still others. Only two of the alkaloids of the bark have been studied, namely, bebeerine and nectandrine. *Bebeerine* ($C_{18}H_{21}NO_3$) is crystalline, though its salts are not. It melts at 198° C. (388.4° F.), is practically insoluble in water, soluble in alcohol, ether, chloroform, amyl alcohol, and acetone, is colored dirty olive-green by concentrated sulphuric acid and brown by nitric acid. This alkaloid is believed to be identical with *buxine, pelosine,* and *paracine. Nectandrine* ($C_{20}H_{23}NO_4$) is amorphous, melts below 100° C. (212° F.), is insoluble in water, slightly soluble in ether, and soluble in chloroform. It gives a green color, changing to violet, wit hsulphuric acid and manganese dioxide. This alkaloid also occurs in the wood. Sulphate of bebeerine, as it occurs in commerce, is a mixed substance. Besides the two alkaloids above described, Maclagan reported having extracted from it the reddish-brown resin-like alkaloid *sipirine.* Nectandra has been recommended for its tonic, astringent, and antiperiodic properties; but as a tonic and febrifuge it is far inferior to cinchona. Its activity is due principally to the alkaloid beberine, the sulphate of which is most generally employed. Nectandra has been successfully administered in the treatment of malarial fevers, but in many cases it has failed to produce the desired result. It has likewise been recommended as a specific for periodical headache and neuralgias of malarial origin. Atonic dyspepsia, menorrhagia, and leucorrhœa resulting from anæmia are also said to have been benefited by its use. The dose of beberine sulphate is from 3 to 5 grains (0.20–0.30 Gm.). As an antiperiodic, from 20 to 40 grains (1.3–2.6 Gm.) of the powdered drug may be given in divided doses between the paroxysms.

SEMEN (FABÆ or COTYLÆ) PICHURIM (*Pichury* or *Pichurim beans, Brazilian beans, sassafras nuts,* E.; *Pichurimbohnen, Sassafrasnüsse,* G.; *Fève pichurim, noix de Sassafras,* Fr.) occur in two varieties, the large produced by *Nectandra Puchury-major* Nees (*Ocotea P.* Mart.), the small by *N. Puchury-minor* Nees (*Ocotea N.* Mart.), both good-sized trees of Brazil. The drug commonly occurs in the form of the separated cotyledons, which are oblong or roundish-oval, plano-convex, marked near one end with a depressed scar left by the detached caulicle, externally blackish-brown, internally light-brown and exhibiting yellow oil-cells; odor and taste resembling those of a mixture of Nutmeg and Sassafras. Those of the larger variety are about 4 Cm. (1½ In.) long and 1.2 Cm. (½ In.) broad; of the smaller, about half as large. With starch, gum, etc., the drug contains about 30 per cent. of fat, partly butyraceous and partly solid, and about 1 per cent. of a volatile oil, of greenish-yellow color, and apparently containing saffrol. Besides their use as an aromatic, substituting nutmeg, Pichury seeds have been considerably employed in medicine and have been recognized in a number of continental pharmacopœias. They have been chiefly used as stimulants and tonics in mild, subacute, and chronic *diarrhœa* and *dysentery,* and in habitual debility of the intestinal canal tending to produce flatulence and diarrhœa. Pichurim bark, which has an aromatic smell resembling that of nutmegs and an astringent taste, is employed in Panama in the treatment of *typhoid states* of the system, in atonic *dyspepsia, chronic vomiting, intermittent fever,* and *menstrual disorders.* The beans are given in powder in doses of from 10 to 20 grains (0.60–1.30 Gm.), or in an infusion; the bark is used in the same forms, and in doses twice as great as these. The oil from the beans has been employed in Europe in the treatment of gouty and rheumatic affections.

The seeds of *Aydendron Laurel* Nees (*Laurus L.*—W.; *Ocotea Pichurim* Humb.), of Venezuela, are used like Pichury seeds.

Canello preto, of Brazil, is the bark of *Nectandra amara* Meissn. (*N. puberula* Nees), and is used as a general aromatic and an emmenagogue. *Canelo de Mato,* of Venezuela, is the bark of *Nectandra cinnamoides* Nees (*Laurus c.*—H. B.), and is used as a cinnamon-substitute; its unripe fruit, like *Cassia Flores.* The bark of *N. sanguinea* Rottb. (*Laurus c.*—Swz.), of Guiana and the West Indies, is similarly used under the name *Maraguan cinnamon. Pao*

Sassafras, of Brazil, is the root of *N. cymbarum* N. et E. (*Ocotea c.*—Humb.; *O. amara* Mart.), and yields a balsam-like oil known as *Aceite de sassafras*. This may be identical with the Venezuelean Camphor-wood oil obtained by the writer, in eastern Venezuela, from an undetermined tree. The latter wood is rather soft, easily split, somewhat silky-lustrous, and yields a little more than 1 per cent. of oil. The latter is light-yellow, has a specific gravity of 1.155, and forms a crystalline mass at ordinary temperatures. It consists to the extent of 90 per cent. of *apiol*.

Caparrapi oil, of Colombia, is a commercial article, and is said to be the product of *Nectandra Caparrapi*, the bark of which has a cinnamon-like odor, and is called *Canello*. The oil is obtained from holes cut into the trunk. Its important constituent is *caparrapiol* ($C_{15}H_{25}OH$), which by dehydration yields *caparrapene*. It is very closely related to the product last named. Both are used as Copaiba-substitutes.

Benzoin or Lindera (*Spice-bush* or *-wood, Fever-bush* or *-wood, Wild allspice, Snap-wood, Benjamin bush*, E.; *Benzoelerbeer*, G.; *Laurier benzoin*, Fr.) is the dried bark of *Benzoin Benzoin* (L.) Coulter (*Laurus B.*—L.; *Lindera B.*—Blume; *B. odoriferum* Nees), a large, much-branched and widely spreading shrub of swamps and damp woods throughout western North America, and extending westward to Kansas. Its light-yellow flowers are produced before the leaves, in earliest spring, in numerous small, dense fascicles, close against the branches, and are succeeded in summer by small, obovoid, deep-red drupes. All parts of the plant are aromatic. Although the leaves and fruit are sometimes employed, it is the bark which constitutes the drug proper. This is mostly collected in the spring, when it can be easily removed in quills, though there are no data for determining the season which yields the best product. The *bark* forms thin quills, is yellowish or pale-brown and smooth upon the inner surface, blackish-brown and minutely dotted with corky warts upon the outer surface, breaks with a short granular fracture, has an agreeable though not very strong odor, and an aromatic somewhat pungent and astringent taste. Older bark has a brown-gray or dark-ash color and more prominent corky warts. The *fruit* is an obovate red drupe about 8 Mm. (⅓ In.) long, after drying blackish and granular upon the surface, and contains a single large white seed having an oily taste, while the fragile integuments of the fruit have a spicy taste, and when bruised an agreeable odor. The bark owes its activity to an unknown bitter principle, and about 0.5 per cent. of a volatile oil of a specific gravity of about 0.923. About one-tenth of this is methyl salicylate, which imparts the odor of wintergreen. The oil of the fruit has a specific gravity of 0.850 to 0.855 and contains a camphor-like body. The leaves yield about 0.3 per cent. of an oil of a specific gravity of 0.888, the composition of which has not been investigated. An infusion made from the small branches of the spice bush has been used as a stimulant and diaphoretic in the treatment of low fevers. The bark is said to possess vermifuge and antiperiodic properties, and the berries were formerly employed as feeble aromatics.

Lindera sericea Blume, *L. triloba* Br., and several other species, of Japan, possess tonic and stimulating properties, and the former yields a fragrant volatile oil which has been introduced under the Japanese name of *Kuromoji oil*. It is contained in all parts, but is distilled for commerce from the leafy twigs. The commercial oil is dark-yellow, of a specific gravity varying from 0.890 to 0.905. It is of complex composition.

California Laurel (*California bay, California wild olive*) is *Umbellularia Californica* (Arnott) Nutt. This plant becomes a good-sized tree in the Californian coast-region and yields a highly prized timber. Its fruit is said to be eaten by the aborigines. Its leaf is the medicinal portion, and is also used for culinary purposes, like the royal bay. It yields about 4 per cent. of a very active volatile oil, of a bright-yellow color and a specific gravity of 0.947, one of the constituents of which is cineol. This oil is apparently the active constituent. With the usual properties of volatile oils, it appears to possess special powers as an intestinal stimulant, overcoming diarrhœas depending upon sympathetic depression. Its power to relieve neuralgia is apparently of the same general nature. It is also a fairly active counter-irritant. The dose of the leaves is from 10 to 30 grains (0.6 to 2 Gm.); of the oil, 2 to 5 minims.

Alligator Pear (*Midshipman's* or *Vegetable butter, Holy ghost pear*, E.; *Avocado*, E., G.; *Avocatier*, Fr.; *Ahuaca, Aquacata*, Sp.) is the fruit of *Persea Persea* (L.) Cockerell (*Laurus P.*—L.; *L. Indica* Sieb.; *P. gratissima* Gærtn.), and the same names are applied to the seeds, which are somewhat used medicinally. The fruit is pear-shaped, sometimes of the size of a very large pear, the surface green or purplish and of a leathery appearance. The pulp is of buttery consistency, yellowish-white with gray veins, and contains a globoidal seed occupying about two-thirds of its diameter. The juice of the seed is milky, reddening upon exposure to the air and finally blackening, and is used as a substitute for indelible ink. Upon fermentation, the seeds yield hydrocyanic acid, from a glucoside which is probably amygdalin. A fluid extract of this remedy has been recommended in the treatment of rheumatism and neuralgia. Formerly it was thought to possess anthelmintic properties, but it probably has little if any such action.

Several species of *Persea* are used in Paraguay under the name *Aynnaudy*. The acrid juice of the root of one of them is used as a febrifuge. *Casca de Lingue*, of Chile, is the bark of *P. Lingue* Nees (*Laurus Lingue* Miers; *L. Linge* Domb.). The barks of several others are used as aromatics, and the fruits of some are edible.

Cryptocarya moschata Mart. (*Mespilodaphne m.*—Meissner) yields a fruit used in Brazil as a nutmeg-substitute and known as *Brazilian nutmeg*. *C. Guianensis* Meissn. is used similarly. The barks of several other species of this genus are used as aromatics.

Pao pretiosa or *Casca p.*, of Brazil, is *Mespilodaphne pretiosæ* Nees et Mart. (*Cryptocarya p.*—Mart.). The bark of *M. Sassafras* Meissn., also Brazilian, appears to contain saffrol.

Bois de Canelle (East Indies) is the bark of *M. Mauritanica* Meissn. (*Oreodaphne cupularis* Nees; *Ceramophora c.*—Schott.; *Laurus Neesiana* Schott.), and is used as a cinnamon-substitute.

Canello de Cheiro (Southern Brazil, Paraguay, etc.) is the bark of *Ocotea opifera* Mart. (*Oreodaphne o.*—Nees et Mart.). The volatile oil of its fruit is also employed. Several other species of *Ocotea* are reported as being employed medicinally as aromatics.

Various species of *Tetranthera*, mostly of the Old World, are similarly employed. *Maidalakri*, or *Muskaip-pe-yetti* (India), is the bark of *T. laurifolia* Jacq. (*T. sebifera* Pers.; *Sebifera glutinosa* Lour.).

Litsea is a large genus of the Orient. The Chinese drug *Wugoh* is supposed to be the root of *L. Myrrha* Nees (*Laurus M.*—Lour.). *Pisatalia* is the fat of the seed of *L. Stocksii* Hook. f., the leaves of which are employed as an aromatic.

Pao Cravo (Brazil) is the bark of *Dicypellium caryophyllatum* Nees (*Persea c.*—Mart.), and is used as a cinnamon-substitute under the name *Cassia caryophyllata*.

Camaran (Guiana) is the aromatic fruit of *Acrodiclidium Camara* Schombk. *Sassafras de Para* is the bark and wood of *A. chrysophyllum* Meissn., of Brazil.

Ai-uba (Brazil) is the starchy and aromatic seed of *Aydendron permolle* Nees. *Canella Abacate* is the bark of *A. floribundum* Meissn.

Ravensara, *Nux Caryophyllata* or *Quatre épiques* (Madagascar), is the fruit of *Ravensara aromatica* Sonn. (*Agatophyllum a.* Willd.; *Evodia Ravensara* Gærtn.).

A number of species of this family are poisonous, usually owing to the presence of the powerful alkaloid *laurotetanine*, which acts in many respects like strychnine. This alkaloid is crystalline and highly insoluble in most solvents. Ether dissolves a very little, chloroform dissolves it with difficulty, and it is soluble in an excess of caustic alkali. It is precipitated by tannic acid and platinum and gold chlorides, gives a pale rose-red color with concentrated sulphuric acid and a dirty brown with concentrated nitric acid. It has been reported as occurring in the following species: *Notaphœbe umbelliflora* Bl., of the East Indies; *Actinodaphne procera* Nees, of Java; *Litsea latifolia* Bl., of the East Indies; *Cassythe filiformis* Bl. (*Calodium Cochin-chinensis* Lour.), of the East Indies; *Aperula spiceosa* Hort.-Bog.; in a bark known in Java as *Baun-trawus*, believed to be the product of *Tetranthera Brawa* Bl., as well as in *T. intermedia* Bl. Poisonous alkaloids, apparently not laurotetanine, occur in *Haasia firma* Miq., *H. squarrosa* Miq., and *Cryptocarya australis* Benth. (*Cyanodaphne a.*—A. Br.), of Australia.

LAURUS.—Laurel.

Bay, Sweet bay, Bay- or *Noble-laurel, Royal bay*, E.; *Laurier commun*, Fr. Cod.; *Lorbeer*, G.; *Alloro*, It.; *Laurel*, Sp.:

1. Folia Lauri (Laurel Leaves, etc.), the leaves, and,
2. Fructus (or Baccæ) Lauri (Bay Berries), the fruit, of *Laurus nobilis* L. (Fam. *Lauraceæ*).

One or both are official in a number of pharmacopœias.

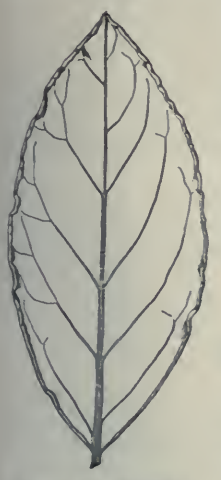
The drug is often confused with Cherry Laurel (*Prunus Laurocerasus*) and with Jamaica Bay or Myrcia, both of which are discussed elsewhere.

Origin.—The Royal Bay is a large evergreen shrub or small tree, native of the eastern Mediterranean region and more or less cultivated in various warm countries. In the northern United States it is often seen growing in tubs for decorative purposes, requiring protection in winter. Its crown is remarkably dense, and of a rich, luxuriant, dark-green appearance. Probably the greatest interest attaching to the Laurel is of a sentimental character, it having been regarded since ancient times as an emblem of victory and success.

Description.—The Leaves.—From 5 to 10 Cm. (2 to 4 In.) long and about one-third as broad, oblong, narrowed and acutish at both ends, very shortly and stoutly petioled, entire but crisped at the margins, very thick and coriaceous, smooth, pale-green or yellowish-green,

the veins finely reticulate and prominent underneath, ending free near the margin; pleasantly aromatic in odor and taste, the latter bitterish, but free from the taste of bitter almond.

Fig. 252.



Royal bay leaf (Nat.).

The Fruit.—About 1.3 Cm. ($\frac{1}{2}$ In.) long, globose-oval, greenish- or brownish-black, more or less wrinkled, the pericarp, inclusive of the brown endocarp, fragile, and brittle, the large oval seed easily separable into its 2 brownish plano-convex cotyledons, and of an oily, aromatic, bitterish taste.

Constituents.—The important constituent of both is the volatile oil (Oleum Lauri), which is also official in several pharmacopœias. The leaves contain about one-third, the fruits about 1 per cent. Besides this, there is an unknown bitter constituent in both. The leaves contain a little tannin, the fruits about 25 per cent. of fat (Oleum Lauri Expressum).

Action and Uses.—Laurel is practically never employed in medicine. The leaves, fruit, and oil, all possess narcotic and stimulant properties; but other more potent remedies have supplanted them. At present the leaves are occasionally used to impart an agreeable flavor to certain articles of diet, and the oil may be employed to overcome the disagreeable odor of various embrocations.

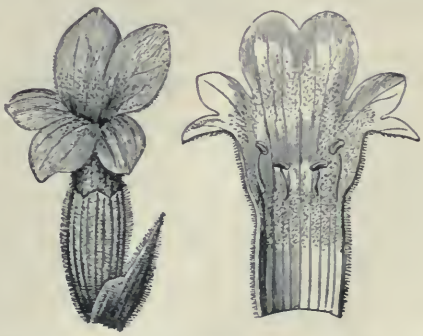
LAVANDULA.—Lavender.

Flores lavandulæ, P. G.; *Flores lavendulæ.—Lavender flowers*, E.; *Lavande officinale*, Fr. Cod.; *Lavendelblüthen*, G.; *Alhucema, Espliego*, Sp.

The carefully dried flowers of *Lavandula angustifolia* (L.) Mill. (*L. spica angustifolia* L.; *L. vulgaris* Lam.; *L. officinalis* Chaix.; *L. vera* DC.—Fam. *Labiatæ*).

Origin.—From a low shrub, native of the Mediterranean basin and everywhere cultivated for ornament or for its perfuming and medicinal properties. The woody portion is short and much branched, the branches densely leafy toward the ends and terminating in long and slender flower-spikes, which have the lower portion naked or nearly so, forming a long, scape-like peduncle, the upper portion becoming densely flowered. The opposite, sessile leaves are 2 or 3 inches long, linear-lanceolate or linear-oblong, thickish, with entire revolute margins and, like the herbage in general, grayish hairy. The flowers, described below, are collected in June and July, before fully expanding, and are carefully dried in the shade. The herbage has a similar odor and composition, and is much used for the same purposes.

Fig. 253.



Lavender flower, with bract, and corolla cut open (× 4).

Description.—Calyx about 4 Mm. ($\frac{1}{6}$ In.) long and half as broad, tubular, slightly contracted at the mouth, which is obscurely 5-toothed, only the upper roundish tooth prominent, 13-nerved, dull-blue and grayish from the dense covering of short roughish hairs and minute glands; corolla nearly twice the length of the calyx, light-blue when carefully dried and fresh, otherwise pale-brown, the tube cylindraceous, enlarged at the throat, glandular-hairy, the limb oblique, 2-lipped, the upper lip erect, of 2 large oval lobes, the lower spreading or declined, of three somewhat smaller lobes; stamens 4, borne at about the middle of the tube, short, not exserted, the lower pair a little the longer; odor strongly aromatic and quite peculiar; taste bitterish, aromatic, somewhat camphoraceous. The nutlets are oval, smooth, rounded at the summit, about 2 to 3 Mm. long by 0.8 to 1.25 Mm. broad.

Constituents.—Besides some tannin, resin, and other widely diffused principles, lavender flowers contain volatile oil, when fresh yielding about 1 per cent. (see Oleum Lavandulæ).

Action and Uses.—Lavender depends upon its volatile oil for its stimulant aromatic properties. It is rarely employed in internal medicine, except in the form of the oil or spirit. Lavender poultices may be applied for the relief of colic, superficial neuralgia, and other local pains. The oil enters into the preparation of certain perfumes.

Allied Plants.—LAVANDULA SPICA Chaix. (*L. latifolia* Ehrhart).—*Spike lavender*, E.; *Spiklavendel*, G.; *Lavande commune*, Fr. Cod.—The plant has spatulate leaves, rather short and dense spikes, and lance-linear bracts. The calyx is finely velvety-hairy, not blue, and about the same length as the calyx-tube. The plant is cultivated in southern France and northern Africa, and volatile oil is distilled from it.

LAVANDULA STŒCHAS L.—*Arabian or French lavender*, E.; *Schopflavendel*, G.; *Stœchas*, Fr.; *Cantuesa*, Sp.—This small shrub grows near the Mediterranean, where the flowering spikes are used. These are short-stalked, and have the small dark-purple flowers in the axils of conspicuous rhombic or obovate, sometimes 3-lobed, purple-colored bracts; the odor is strongly aromatic, camphoraceous.

LECYTHIDACEÆ.—The Brazil-nut Family.

This is a small family of between 100 and 200 species, mostly trees, of tropical regions. Although the seeds of a number of species are used as fish poisons, and some are poisonous to man, the importance of the family is chiefly due to its production of a number of seeds, so-called "nuts," highly nutritious and of delicious flavor. The ordinary Brazil-nut (*Para-, Cream-*, or *Castana-nuts*, or *Nigger-toe nuts*, E.; *Chatiagne du Brésil*, Fr.) is the product of *Bertholletia excelsa* H. et B. The use of these nuts in the North as a luxury, or dessert, gives little idea of their high importance as a food-product in the country of their production. They are rich in oil, for which important uses could doubtless be found. Still more delicious are the *Sapucaja nuts*, *Cream-nuts*, or *Monkey-pot nuts*, produced by various species of *Lecythis*, of tropical America. These nuts are so highly esteemed at home that they are very rare in commerce.

The poisonous seeds of the family belong chiefly to the genus *Barringtonia*, representing both Old and New World species. Apparently, these owe their poisonous properties, chiefly if not wholly, to the presence of saponin. The seeds of *Lecythis minor* Jacq., of the northern part of South America, are narcotic. Other poisonous species belong to the genus *Gustavia*. *Jamparandiva* (Brazil) is the root of *G. Brasiliana* DC. *Chupo* (Colombia) is the fruit of *G. speciosa* DC., and is used in jaundice, The Colombian *Membrillo* or *Baco* is the fruit of *G. superba* Berg. (*Pirigara s.*—H. B. K.; *G. angusta* DC.). *Kayo-umur-ponjang*, of the East Indies, is the leaves of *Grias cauliflora* L., and is drunk as a substitute for tea.

LEGUMINOSÆ.—The Bean Family.

The Leguminosæ comprise the following three subfamilies, or, according to some authors, distinct families: *Papilionaceæ* (the Bean Family proper), distinguished by its butterfly-shaped flowers, their upper petal enclosing the lateral ones in the bud; *Cæsalpiniaceæ* (the Senna Family), distinguished by flower-buds in which the lateral petals envelop the upper one; *Mimosaceæ* (the Acacia Family), distinguished by flower-buds having the petals valvate. The entire family comprises about 450 genera and 6000 species. From a biological standpoint, it represents the highest embryological development as to both structure and nutrition, and its powers of variation and adaptation to environment are second to those of no other family. It ranks in economic importance among the first three or four families of the vegetable kingdom. This preëminence in useful products relates to drugs, foods and fodders, fixed oils, tanning and dyeing materials, and timbers, besides which, the importance of its poisonous products takes high rank.

Many of the tropical trees of the Leguminosæ, especially in the subfamilies Cæsalpiniaceæ and Mimosaceæ, yield timbers of the greatest value, because of their hardness, durability, and polishing properties, and in many cases because of the contained coloring-matters, which give them great beauty in cabinet-work.

The family is rather rich in dyestuffs, many of which, like BAPTISIA, were much employed in former times. A number of these, pertaining to heart-woods of the *Cæsalpiniaceæ*, are mentioned under HÆMATOXYLON. Others, pertaining to herbage, are treated under INDIGO. A few owe their coloring properties to the tannins which they contain, and these are discussed under QUERCUS.

Many members of the Leguminosæ are rich in tannin, and are used both for tanning purposes and as medicinal astringents. These belong chiefly to the subfamily *Mimosaceæ*, are rather common in the *Cæsalpiniaceæ*, and infrequent among the *Papilionaceæ*. The parts so used are usually barks, frequently woods, and occasionally fruits. All these will be found discussed under QUERCUS.

The fixed oils of this family, of which peanut-oil may be regarded as the type, will be found described under OLEA PINGUIA.

Foods and Fodders.—The nutritive properties of the Leguminosæ are of the highest importance, even from the ordinary dietetic standpoint; but they possess, in addition, important medicinal relations. The high nutritive ratio (see GRAMINEÆ) of these food-products is illustrated by the composition of those included in the following table:

NUTRITIVE COMPOSITION OF SOME IMPORTANT HUMAN AND STOCK FOODS OF THE LEGUMINOSÆ.

Food-stuffs.

	Albuminoids.	Fat.	Carbohydrates.	Nutritive ratio
Peas	22	2	52	1 : 2.9
Beans	25	1.6	46	1 : 2.7
Lentils	25	1.85	55	1 : 2.4
Soy beans	35	17.6	6	1 : 1.2
Peanuts	26	47	24	1 : 5.3

Fodders.

Red-clover hay	13.5	3	37	1 : 5
Pea-vines	14	2.6	34	1 : 4
Bean-vines	28	2.5	58	1 : 2.3
Alfafa	16	2.5	32	1 : 2.8
Vetch-hay	20	2.3	29	1 : 2.3
Lupine-hay	17	2.2	31	1 : 3.4

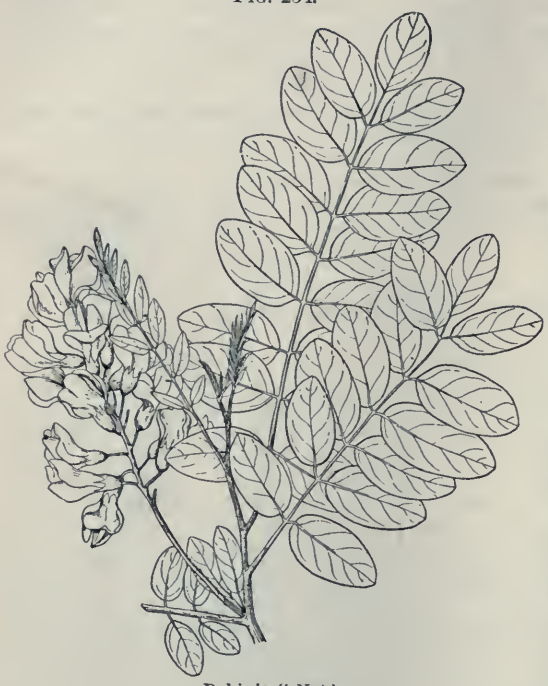
It will be noted that the above substances are not only rich in albuminoids, but also that in some cases their carbonaceous matters are largely fatty; such foods are those peculiarly applicable for use by diabetic subjects. The Soy or Soja Bean has been especially recommended for this purpose, preferably after the removal of its not very agreeable fixed oil, which has distinctly cathartic properties. The residue is then, in Oriental countries, often ground and used for bread-making for such patients. A kind of cheese is also largely prepared from the seed. Soy Bean is also known as *Chinese* or *Sahuca bean*, *White gram*, or (*Japanese*) *Miso*. It is the seed of *Glycine hispida* Maxim. (*Soja h.*—Moench), and of the perhaps distinct species *G. Soja* (L.) Sieb. et Zucc. (*Dolichos S.*—L.), which are climbing herbs, natives of eastern Asia, and largely cultivated there and in other warm countries. The nutritive value of this bean is estimated to be nearly double that of lean meat.

Leguminous foods and fodders, with the above-mentioned advantages, combine some distinctly objectionable characters. Even the best of them, as peas and beans, contain undetermined substances, in all probability albuminous, which may produce injurious results; becoming more or less poisonous when the articles are used upon an extensive scale, as when pea-meal or bean-meal, or even clover-hay, is too freely fed to horses or cattle. MacDougal (*Pharm. Jour.*, 1897, 290) has collected evidence of the poisonous character of such foods, showing that their continued excessive use may produce paralysis of the lower limbs, and that instances have occurred in which their use, on account of these properties, was forbidden by law. The parts most often attacked by these subtle poisons pertain to the epidermal system. In horses, an inflammation (*lamellitis*) is very apt to occur between the foot and the hoof, and the latter may even fall off. In cattle, the horns may become diseased. The hair becomes poorly nourished, and appears dry and rough or even falls out. Thus, in the West Indies, a disease known as "Cigar-tail," in which the tail becomes bare of hair, is said to be the result of eating *Leucæna glauca*.

Poisons.—The poisonous properties of the Leguminosæ are of the highest interest and importance. They very often depend upon the presence of easily determinable compounds, alkaloids or glucosides, as in PHYSOSTIGMA, SCOPARIUS, etc., but probably in a much greater number of cases are due to albuminous substances, well illustrated by those of ABRUS. In the latter class of cases, not only are the constituents extremely difficult to determine and isolate, but the effects are also very obscure in their nature, as well as very severe and intractable. A good illustration of this class of poisons is found in *Robinia Pseudacacia* L. (*Pseudo-Acacia vulgaris* Medic.; *P. odorata* Moench), the *Common*, *White*, *Black*, *Post*, *North American*, or *Pea-flower locust*, *False acacia*, *White laburnum*, *Whya tree* (*Falsche Acazie*, G.; *Robinier*, Fr.), a good-sized tree of the eastern United States, highly prized for its ornamental properties and for its timber, which is exceedingly durable. Its stipules become thorny and persist for some years. The leaves and handsome fragrant white or sometimes slightly purplish flowers are here illustrated. The fruit is a linear, flat, usually 6-seeded legume, about 8 Cm. (3 In.) long and margined on the inner side. The root and inner bark have a sweetish but somewhat offensive or nauseating taste, and have been found poisonous to foraging animals. F. B. Power (1901) isolated from the inner bark a poisonous nucleoproteid *robin*, which has

an acid reaction, is soluble in water and in salt solution, and is precipitated from its solutions by acids. On heating its aqueous solution it becomes coagulated, its poisonous properties being destroyed at water-bath temperature. It is capable of hydrolizing both amygdalin and potassium myronate, with formation of the volatile oils of almond and mustard, respectively, and is capable of coagulating the casein of milk, as also of agglutinating or clotting the red blood-corpuscles of certain animals. Robin possesses strong emetic and purgative properties. The bark furthermore contains one or more substances of an alkaloidal character, easily decomposed and probably representing degeneration-products of the proteid. Dextroglucose, a small amount of tannin, and considerable fatty matter and resin have also been found. (For a full account of the chemical examination of the bark, see *Pharm. Jour.*, Aug., 1901.)

Fig. 254.



Robinia (⅛ Nat.).

Although the leaves of the Robinia have been stated to produce poisonous effects (Blyth, *Poisons*, 3d edit., 1895), careful examination has failed to detect the presence of any soluble proteid, or of alkaloids (Power). By some the leaves have been recorded as even affording wholesome food for cattle.

According to Zwenger and Dronke (1861), the flowers contain a yellow glucoside, *robinin*, which, on being boiled with acids, is resolved into sugar and *quercetin*. Tonic, emetic, and purgative properties have been ascribed to the root and bark of the locust tree, but the plant is rarely if ever prescribed as a therapeutic agent. Occasional cases of poisoning are on record in which boys have chewed the bark and swallowed the juice; the principal symptoms being dryness of the throat, burning pain in the abdomen, dilatation of the pupils, vertigo, and muscular twitching. Excessive quantities occasion, in addition to the above symptoms, great circulatory depression, the heart's action becoming weak and irregular.

Loco.—One of the most notable and curious instances of poisonous properties in plants is that of the group of species known in the grazing regions of the western United States as *Loco* or *Loco-weed*, "loco" being the Spanish word for *crazy*. These species pertain chiefly to the two genera *Astragalus* and *Aragalus* (*Oxytropis*), and many species have been designated by different authors as producing the baneful results. The common *Yellow rattle-box* of the eastern United States (*Crotalaria sagittalis* L.) is said to act similarly. Though many chemists have sought for the constituents, none have been able to locate the active properties, the trace of alkaloids, resins, volatile and fixed oils, having each in turn been found destitute of it. Yet the poisonous properties are fully established by field observations. The destructiveness of these plants to stock is so great as to have probably caused upward of a million dollars loss in the aggregate, and large bounties have been offered by State governments for an effective method of avoiding such losses. It is considered very probable that the poisonous constituent is albuminoidal.

Other members of the family which are of greater interest on account of their poisonous properties than from a medicinal point of view are the following:

Laburnum, *Golden chain* or *Golden shower*, *False ebony*, *Bean-trefoil*, *Ile-broom* (*Goldregen*, *Bohnenbaum*, G.; *Cytise*, *Faux Ebénier*, Fr.), is *Cytisus Laburnum* L. (*Laburnum anagyroides* Medic.; *L. vulgare* Presl.; *L. Cytisus* L.), a tall shrub or low tree of southern Europe, and much planted for decorative purposes. The bark is smooth, the leaves slenderly petioled and trifoliolate, the leaflets sessile, oval-oblong, obtuse, mucronate, about 5 Cm. (2 In.) long and two-thirds as broad, softly grayish-hairy underneath, and of a salty, bitterish, and slightly acrid taste. The golden-yellow flowers are in long drooping racemes, and are followed by linear, obtuse legumes, containing dark-brown, glossy, nearly reniform seeds of a disagreeably bitter and acrid taste. The seeds constitute the principal poisoning agent, though the leaves share their property. The seeds contain the crystalline alkaloid *cytisine* ($C_{11}H_{14}N_2O$), which has a melting-point of 154° C. (309.2° F.), is very soluble in water, alcohol, amyl alcohol, and caustic alkalies, scarcely in ether or chloroform, is precipitated by gold chloride

and picric acid, and is colorless with sulphuric acid. *Laburnic acid* has been isolated, and is supposed to be in combination with the alkaloid. Other bitter principles have been reported (*cystin* and *laburnin*), and are probably glucosides, though little is known of them. Both laburnum and its alkaloid cytisine have been advocated as remedies in the treatment of congestive headache, asthma associated with emphysema, whooping-cough, dyspepsia, and the nausea and vomiting of pregnancy. Its employment in these conditions is rare as it has met with little favor among physicians. In medicinal doses the drug produces a soporific effect and a tendency to constipation. Overdoses cause nausea and vomiting, tetanic convulsions, respiratory depression, and a marked elevation of blood-pressure with a notable increase in the pulse-rate. Dryness of the throat, abdominal pain, weakness of the extremities, vertigo, dilated pupils, and deep sleep are also marked symptoms. The treatment of poisoning by this drug should consist in the prompt evacuation of the stomach, and the administration of alcohol, ammonia, and other stimulants as indicated. An extract prepared from laburnum may be given in doses of from $\frac{1}{10}$ to 1 grain (0.006–0.06 Gm.). The dose of cytisine is from $\frac{1}{20}$ to $\frac{1}{12}$ grain (0.003–0.005 Gm.).

Sophora is a genus which yields a number of poisonous seeds. *S. secundiflora* (Cav.) DC. (*S. speciosa* Benth.) is the *Coral bean* or *Frijolito*, a small evergreen tree of western Texas and southwestward. It has smooth, oddly pinnate leaves, with 3 to 5 pairs of leaflets, which are about 25 Mm. (1 In.) long, ovate in shape, obtuse or somewhat pointed, dark-green and glossy above and pale-green beneath. The flowers are in dense racemes, blue or tinged with white, very fragrant, and have a bell-shaped small calyx and 10 nearly free stamens. The pod is indehiscent, 5 to 8 Cm. (2–3 In.) long, nearly terete, or more or less constricted between the seeds, tough, and covered with a pale brownish-gray pubescence. The seeds are globular-ovate, about 1 Cm. ($\frac{2}{5}$ In.) long, somewhat depressed on the hilum, and of a bright-red color. The active constituent, or at least one of them, is the amorphous alkaloid *sophorine*, which is soluble in nearly all ordinary solvents, gives a dirty deep-purple color with sulphuric and chromic acids, passing through bright-green and bluish into yellowish-brown; and deep-red, after a time orange, with ferric chloride.

S. Japonica L. is the *Pagoda tree*, *Chinese berry tree*, *Waifa* or *Yen-ju*, of China and Japan, and somewhat cultivated for ornamental purposes. The flower-buds are said to be used as a substitute for hops and for dyeing yellow. These buds owe their coloring properties to two substances which have been called, respectively, *sophorin* and *sophoretin*, the latter resembling quercetin.

Wistaria, the highly ornamental cultivated woody twiner of that name, *Kraunhia Chinensis* (Sims) Rusby (*Glycime C.*—Sims; *Wistaria C.*—DC.), is intensely poisonous in all its parts, but especially as to the roots. The poisonous constituent has not been studied, but its effects are said to be similar to those of poisoning by Laburnum. The recorded symptoms are vomiting, intense diarrhœa, convulsions (sometimes tetanic), frothing at the mouth, unequally dilated pupils, and coma. In less severe cases there have been observed great drowsiness, mydriasis, loss of pupillary reflex, and widespread anæsthesia.

Lupinus is a large genus, the poisonous properties of which are apparently very irregularly and unequally distributed. A number of the species are cultivated for fodder, and, if not over-fed, are found highly nutritious and wholesome. If the seeds, at least of certain species, are eaten, in a more or less mature condition, poisoning is liable to occur, great numbers of animals sometimes being fatally affected. These poisoning accidents have occurred in Europe and in the United States, the latter cases sometimes produced by the European species here cultivated, sometimes by our native species. It is very doubtful if the poisonous constituents are the same in all the species, or even if a single species do not contain more than one; thus the identity of the substances reported upon by different investigators is thrown into considerable doubt. The species best known in this connection is the common *White lupine* of cultivation (*Feighbohne*, *Wolfsbohne*, G.; *Lupin*, Fr.; *Altramuz*, *Coochos*, Sp.), the seed of *L. albus* L., native of southern Europe and adjacent Asia. The plant is about 50 Cm. (20 In.) high, and has palmately 5- or 7-foliolate leaves, with the leaflets obovate-oblong, 25–50 Mm. (1 or 2 In.) long, smooth above and white hairy beneath; the flowers are in terminal racemes on short pedicels, white and rather large; the legume is 7–10 Cm. (3–4 In.) long, flattish, and contains 3 to 6 white circular and flattened seeds, which are inodorous and have a somewhat bitter taste. The *Yellow lupine* of the same region is *L. luteus* L., so called from its yellow flowers. The blue-flowered species of the northeastern United States is *L. perennis* L., the *Wild* or *Blue bean*. In the western United States and southward into the Andes the species are very numerous, and their specific relations highly perplexing. The following constituents have been isolated: *lupinin* ($C_{29}H_{32}O_{16}.7H_2O$), a bitter glucoside occurring in yellowish needles, soluble in caustic alkalies and with difficulty in water or alcohol, precipitated by basic lead acetate; the alkaloid *lupinine* ($C_{21}H_{40}N_2O_2$), occurring in rhombic crystals, melting at 67° to 80° C. (152.6° to 176° F.), soluble in cold, less in warm water, soluble in alcohol, ether, and chloroform; the liquid yellow alkaloid *lupinine* ($C_{15}H_{24}N_2O$), agreeing in its solubilities with the last, except that it is with difficulty soluble in alcohol; and *lupinidine* ($C_8H_{15}N$), which is pungent as well as bitter, soluble in

water and alcohol, but with difficulty in ether. Willstater states that the formula given above and accepted by other authors for lupinine is in reality $C_{10}H_{19}NO$, and that it is in nature a primary alcohol.

Derris.—Several species of this genus are employed as fish poisons. Farr has examined *D. uliginosa* Benth., and has traced its poisonous action on fishes to a resin soluble in chloroform or to some substance carried with that resin. The alkaloid present appeared inactive in this direction. An exhaustive study of the chemistry of the stem of this plant has recently been made by F. B. Power (*Proc. Am. Pharm. Assoc.*, 1902, p. 297 et seq.).

Gymnocladus.—The pulp around the seeds of this plant is said to be an effective fly poison. The seeds contain considerable fixed oil.

Enterolobium.—A number of species of this genus contain saponin, and are used as fish poisons. The same may be said of the barks of several species of *Albizzia.*

Drugs.—The more important drugs of this family (Abrus, Acacia, Balsamum Peruvianum, B. Tolutanum, Baptisia, Cassia Fistula, Chrysarobinum, Copaiba, Erythrophlæum, Fœnum Græcum, Glycyrrhiza, Hæmatoxylon, Indigo, Physostigma, Piscidia, Scoparius, Senna, Tamarindus, Tragacantha, etc.) will be found described under these titles. Others have been incidentally discussed above, in connection with the poisons. Less important members of the class are considered below. Very frequently the drugs of this family owe their properties to constituents closely related in physiological and therapeutical activity, if not in constitution, to those of Scoparius, under which title they will be found discussed.

Andira or *Cabbage-tree bark* (*Kohlbaumrinde, Wurmrinde*, G.; *Écorce de geoffrée*, Fr.) presents two varieties, (1) the bark of *Vouacapoua inermis* (Swz.) Lyons (*Geoffræa i.* Swz.; *Andira i.* Kunth), the *Jamaica* variety or *Partridge-wood bark*, also called *Yellow cabbage-tree bark;* and (2) that of *V. retusa* (Poir) Lyons (*Geoffræa r.*—Poir.; *Andira r.*—Kunth), the *Surinam* or *Brown cabbage-tree bark* or *Surinam bark.* The former occurs in long pieces about 3 Mm. ($\frac{1}{8}$ In.) thick, gray or whitish, and fissured externally, upon the inner surface brownish and striate, internally brown or brownish, radially striate, and with yellowish bast-fibers in tangential rows, which cause the laminated fibrous appearance of the bark when broken transversely. It yields a grayish powder, and has a feeble but disagreeable odor and a mucilaginous bitter taste. *Surinam* cabbage-tree bark resembles the preceding, but is internally dark red-brown, has a checkered and glossy appearance on transverse section, yields a cinnamon-colored powder, is nearly inodorous, and has a bitterish-acrid taste. The Surinam variety has been found to contain the alkaloid *ratanhine* ($C_{10}H_{13}NO_3$), having a melting-point of 40° to 45° C. (104° to 113° F.), neutral and tasteless, scarcely soluble in water, alcohol, ether, or chloroform, but soluble in benzene and in an excess of caustic alkalies, and giving a violet reaction with ferric chloride. Ratanhine is regarded as identical with *angeline*, originally extracted from a kino-like exudation from the tree *Ferreira spectabilis* Allem., of Brazil; also with methyl-tyrosin. This variety contains also a large amount of tannin. The Jamaica variety is said to contain berberine. The seeds of *V. vermifuga* (St. Hil.) Kuntze (*Geoffræa v.*—St. Hil.; *Andira v.*—Mart.; *A. anthelmintica* Benth.) are known as *Angelim seeds, A. dolce* or *A. amargosa*, and have been considerably used for their anthelmintic properties. They are of the size of a nutmeg, oblong, somewhat horny, yellowish, internally whitish, almost devoid of odor and taste. They usually occur in transverse or longitudinal sections. This species contains a cathartic and anthelmintic resinous substance.

Bonduc seeds or *nuts*, also known as *Nicker nuts, Benzor nuts*, or *Molucca beans*, are the seeds of *Guilandina Bonduc* L. (*Cæsalpinia B.* Roxb.; *G. glabra* Mill.), the yellow variety; and of *G. Bonducella* L. (*Cæsalpinia B.* Roxb.; *G. aculeata* Salisb.), the gray variety. They are the products of prostrate prickly shrubs growing in nearly all tropical and subtropical countries, especially near the coast. The gray variety occurs 2 or 3 in a pod, this giving them a somewhat angularly spheroidal form, the yellow variety but 1 in a pod, hence nearly spherical. The latter are somewhat smaller, being about 1.2 to 1.5 Mm. ($\frac{1}{2}$ to $\frac{3}{5}$ In.) long, the gray ones 1.8 to 2 Cm. ($\frac{3}{4}$ to $\frac{4}{5}$ In.) long. Both are very smooth and somewhat shining, and about as hard and heavy as an ordinary kidney bean, or possibly of a somewhat higher specific gravity. Their structure is that of the ordinary leguminous seed. Like other leguminous seeds, their composition is largely albuminoidal (20 to 22 per cent.), and there is about 35 per cent. of starch, 5 or 6 per cent. of sugar, 25 per cent. of fixed oil, and about 2 per cent. of a peculiar bitter substance soluble in alcohol and ether and slightly in water, which has not been investigated. The oil is largely used in the East Indies as an embrocation. The seeds themselves, as well as the root-bark, are considerably used in all tropical countries as antiperiodics. Bonduc seeds are employed principally in India in the treatment of intermittent fever and the debility following acute infectious diseases. The dose of the seeds is from 10 to 15 grains (0.60–1 Gm.). Pulvis Bonducellæ Compositus (P. I.), consisting of bonduc and black pepper, is administered in doses of from 15 to 20 grains (1–1.3 Gm.).

Fructus ceratoniæ, Ceratoniæ Fructus, or *Siliqua dulcis* (*St. John's bread, Sweet-pod, Honey-bread, Locust-bean, Carob-tree bean,* E.; *Johannisbrod, Soodbrod, Karobe,* G.; *Caroube, Carouge,* Fr.; *Garrobo, Algarroba de Valenca,* Sp.), is the dried fruit of *Ceratonia Siliqua* L., a good-sized tree, native of the Mediterranean region and cultivated in warm countries. It is said to be the "Locust" which fed St. John the Baptist. The fruit is 10 to 20 Cm. (4 to 8 In.) long, nearly 25 Mm. (1 In.) broad, about 3 or 4 Mm. ($\frac{1}{8}$ or $\frac{1}{6}$ In.) thick, obtuse, linear, much flattened, and with somewhat elevated edges, causing the transverse section to be narrowly and obtusely rectangular. The epicarp is leathery, brown, glossy, finely striate, and encloses a light-brown softer sarcocarp of a pleasantly sweet taste. The seeds, 6 to 12 in number, are flattish ovate and polished brown, and are contained in separate transverse cells formed by the papery inner layer of the pericarp. The fruit contains 40 to 50 per cent. of cane- and grape-sugar, besides mucilage, protein compounds, a little tannin, and butyric acid, to which the odor is due. Aside from its sweetness and edible properties, it is credited with some mild expectorant and demulcent action.

Saman.—The fruit of *Pithecolobium Saman* Benth. (*Calliandra S.*—Griseb.), as well as of *P. dulce* Benth., of the East Indies, and cultivated in all tropical countries, is used as a substitute for St. John's bread. Its seed, as well as those of other species of the genus, contains an alkaloid called *pithecolobine.* The fruits of several species of *Prosopis* are similarly sugary and similarly used.

Galega or *Goat's rue, Herba rutæ capriariæ* (*Geisraute, Pestilenzkraut,* G.; *Rue de Chèvre,* Fr.), is the herb of *Galega officinalis* L., of the Mediterranean region and southern Europe. It has a perennial several-headed root and an erect stem about 90 Cm. (3 Ft.) high; the smooth, oddly pinnate leaves are furnished with 6 or 8 pairs of lanceolate or ovate-lanceolate, obtuse, and finely mucronate leaflets 2–5 Cm. ($\frac{3}{4}$–2 In.) long, and with lanceolate stipules, which are sagittate on one side. The purplish or whitish flowers are in axillary racemes, and produce narrow, almost cylindrical legumes. The herb is inodorous and has a mucilaginous and somewhat bitter and astringent taste. Its constituents have not been investigated.

Melilotus or *Melilot, Herba meliloti* P. G. (*Sweet, King's, Hart's, Tree,* or *Plaster clover, Sweet Lucerne,* or *Wild laburnum,* E.; *Melilotenklee, Steinklee,* G.; *Mélilot officinal,* Fr. Cod.; *Meliloto, Trebol oloroso,* Sp.) is the dried leaves and flowering tops of several species of *Melilotus, M. alba* Desv. (*M. vulgaris* Willd.) being the white variety, and *M. officinalis* (L.) Lam. (*Trifolium Melilotus officinalis* L.; *M. arvensis* Wallr.; *M. diffusa* Koch) and *M. altissimus* Thuill. (*M. officinalis* Willd.; *M. macrorrhizus* Pers.) being the yellow-flowered species. All three are natives of Europe, and are perennial herbs from 2 to 4 feet high, growing in dry fields and along roadsides. The drug of the German Pharmacopœia, and that generally understood, pertains to *M. officinalis* Lam. Its stipules are entire, awl-shaped; the petiolate trifoliolate leaves have oval or obovate-oblong leaflets, the lower ones notched, the upper ones truncate at the apex, entire near the base, and somewhat sharply serrate above, about 2 to 3 Cm. ($\frac{4}{5}$ to $1\frac{1}{4}$ In.) long; the flowers are in spreading or ascending racemes, and the reflexed legumes are brown or blackish. The keel of the flower is much shorter than the other parts, and the obovate, transversely wrinkled legume is 1-seeded. In *M. altissimus,* the keel is as long as the other parts and the obliquely oval, pointed, reticulately wrinkled pod is 2-seeded. *M. alba* is readily distinguished by its white flowers. All the species have a strong, peculiar, and not altogether agreeable odor in the fresh state, but in drying develop cumarin and exhale the pleasant odor of that substance. The taste is somewhat pungent and bitterish. The cumarin is the only important constituent, together with its related compounds (see *Cumarin*), *hydrocumaric* (*melilotic*) acid, *orthocumaric* acid, *melilotic anhydride* or *lactone,* a sort of volatile oil. Melilotus was formerly employed internally in the treatment of flatulent diarrhœa, dysmenorrhœa, and rheumatism. Externally it is occasionally applied in the form of a plaster or ointment for the relief of abdominal and rheumatic pains.

Mucuna or *Cowhage* (*Setæ siliquæ hirsutæ.*—*Kuhkrätze,* G.; *Pica-pica,* Sp.) is the hairs removed from the pods of *Mucuna pruriens* (L.) DC. (*Dolichos p.*—L.; *Stizolobium p.*—Medic.; *Carpopagon p.*—Roxb.; *M. prurita* Hook.), the seeds known as *Sea beans, Ass's* or *Donkey's eyes* (E.); *Kratzbohnen* (G.), *Pois velue, Pois à Gratter* (Fr.), a tall, climbing, bean-like plant of the tropics of both the Old and New Worlds. Similar hairs occur upon the pods of the closely related species *M. urens* Medic. (*Stizolobium u.*—Pers.), of tropical America. Cowhage hairs are about 3 Mm. ($\frac{1}{8}$ In.) long, of a glossy-brown color, straight, quadrangular-prismatic, sharply pointed at the apex, somewhat retrorsely serrate on the upper half, and partly empty, partly filled with a brown granular matter. They easily penetrate the skin, and occasion an intolerable itching, which is greatly increased by washing and rubbing. Those of the second-named species are shorter and darker. The medicinal use of Cowhage depends wholly upon the irritating properties of the hairs. The seeds of these plants are the well-known Sea beans, picked up along the coast of Florida and the West Indies and polished for ornamental purposes. They are credited with diuretic properties, as are the roots.

Psoralea is a genus of more than a hundred species of herbs or shrubs, quite a number of which have been used in medicine under the above name (*Psoralie, Drüsenklee,* G.; *Psorale,*

Fr.). The genus is characterized by a 5-cleft persistent calyx having the lowest lobe longest, by diadelphous or sometimes monadelphous stamens, by a short 1-seeded pod, the pointed end of which projects from the calyx, and by the glandular dots with which the calyx, and frequently also the leaves, are more or less covered. The best known is the East Indian species *P. corylifolia* L., the seeds there used under the name *Bauchee* or *Bawchang seed*, the leaves as *Malay tea*, in indefinite ways as a cutaneous tonic and alterative. In the southeastern United States *P. pedunculata* (Mill.) Vaill. (*Hedysarum p.*—Mill.; *P. melilotoides* Mx.; *P. eglandulosa* Ell.) is used as an aromatic bitter tonic under the names *Samson's snakeroot*, *Bab's root* or *Congo root*. It is a slender, erect, pubescent, and slightly glandular herb, and has a spindle-shaped root, trifoliolate leaves with oblong-lanceolate rather obtuse leaflets, and long-peduncled, oblong, finally elongated spikes of purplish flowers; the legume is nearly orbicular and transversely wrinkled. The plant has a slight aromatic odor and a somewhat spicy and bitterish taste. It flowers in June and July, and should be collected when in full bloom. *P. glandulosa* L. is used in Chile for its aromatic properties, like Rue, and its root as an emetic. *P. pentaphylla* L. is similarly used in Mexico, as well as for the cure of snakebites, under the name *White contrayerba*. The tuberous root of *P. esculenta* Pursh. was an important aboriginal food in the western and central United States, and is known as *Bread root*, *Prairie apple*, *Cree* or *Dakota potato* or *turnip*, *Tipsin* or *Tipsinna* (*Pomme Blanche* or *Pomme de prairie*). A smaller tuber is derived from the closely related species *P. hypogæa* Nutt.

Tephrosia, the herbage of *Cracca Virginiana* L. (*Galega V.*—L.; *Tephrosia V.*—Pers.), is also known as *Goat's rue* (*Turkey pea*, *Hoary pea*, *Catgut plant*, *Devil's shoestrings*, *White sweet pea*, *Rabbit pea*, E.; *Tephrosie*, G., Fr.). It is a perennial herb of eastern and central North America. Its root is many-headed and divided into several nearly horizontal branches which are about 12 Mm. ($\frac{1}{2}$ In.) in diameter, 30–60 Cm. (1 to 2 Ft.) long, somewhat beset with fibers, rather tough and flexible, externally brown-gray and internally whitish. The stems are about 60 Cm. (2 Ft.) long, nearly simple, more or less woolly, and have numerous alternate, odd-pinnate leaves, with about 10 pairs of oblong, mucronate, shortly-stalked, straight-veined, and silky-villous, pale-green leaflets. The flowers are in terminal and axillary racemes, white, rose-colored, and red, and produce a curved silky legume. The root and occasionally the herb have been employed; the root is without odor and has a bitterish and somewhat acrid taste. This species is used as an anthelmintic. Many tropical species of the genus are notoriously poisonous, and *C. piscatoria* (Sol.) Lyons (*Galega p.* Sol.; *G. littoralis* Forst.; *Tephrosia purpurea* Pers.; *T. piscatoria* Hilleb.; *T. leptostachya* DC.), the *Auhuhu* or *Hola*, and *C. toxicaria* (Pers.) Lyons (*Tephrosia t.* Pers.), are used as fish poisons. *C. Apolinea* (Delile) Lyons (*Tephrosia A.* Link; *Galega A.* Delile), of southern Europe, is an indigo-yielder, known as *Egyptian indigo*, and its leaves have been used to adulterate Senna.

The bark of *Albizzia anthelmintica* (Baill.) Courd. (*Acacia a.* Baill.; *Besenna a.* Rich.) is an important anthelmintic in Abyssinia under the names *Mussena*, *Mesenna*, *Bussena*, and *Bisinna*. It also occurs in European commerce, in flat or bent pieces 2 to 5 Cm. (1–2 In.) wide, and 5 Mm. ($\frac{1}{5}$ In.) thick, and 30 Cm. (12 In.) long, gray or yellowish-brown, smooth or somewhat fissured, the middle bark granular and yellowish and the tough bast pale-yellow; it is inodorous, and the inner layers have a nauseous sweet, bitterish, and persistently acrid taste. Thiel (1862) showed the presence of a saponin-like amorphous body, *musenin*, bitter, saccharine, and coloring principles, and about 5.5 per cent. of ash. The infusion is colored yellow by ferric chloride. The Abyssinians are said to take from 3 to 4 ounces (90–120 Gm.) of the powdered bark made into an electuary with honey, after fasting for 24 hours. The parasite is discharged, neither whole nor in fragments, but reduced to a sort of pulp. The medicine thus administered is apt to occasion nausea, but neither colic nor diarrhœa, and its use is followed after several hours by a purgative, usually castor oil. When musenna has been employed in Europe, it has generally failed to produce the results as a tæniacide which are attributed to it in its native country.

Besides its use as a food, the Horse-bean (*Faba vulgaris* L.) is a popular remedy for diarrhœa, and the ash of the burned stalks infused in white wine is a popular diuretic in France. A watery infusion of the flowers has been vaunted as an efficient remedy for attacks of gravel and for the nodosities caused by gout.

Daviesia latifolia R. Br. is a hop-like climber of Australia, where it is known as *Native hop bush*. It has a very bitter taste, and contains an oleoresin and a crystalline amaroid soluble in hot water and weak alcohol, but insoluble in ether. The drug is used as a bitter tonic. In Brazil, the bark of *Stryphnodendron Barbatimao* is used under the name *Barbatimao* as an astringent. The seeds are poisonous. In the Philippines the root-bark of *Clitoria Ternatea* L. is used under the name *Kolokantig* as a sedative diuretic, and the seeds are emeticocathartic. In the same country the bark of *Agati grandiflora* Desv. is used under the name *Katuray* as a bitter tonic, the flowers and leaves as a bitter purgative. *Bowdichia major* Mart. is used in Brazil under the name *Sebipira guacu* in the treatment of fevers and of rheumatic and gouty pains.

Medicago.—The flowers of the common *Lucerne* or *Alfafa* (*Medicago sativa* L.) contain a peculiar odorous principle having the fragrance of Elm bark, and have a considerable domestic use as an ingredient of cough remedies.

Trifolium.—During recent times, the flowers of the common *Red clover* (*T. pratense* L.) have come into use as a constituent of a popular alterative compound, but we have no information to indicate that they possess medicinal properties.

In Sierra Leone a fragrant exudation from *Daniella thurifera* Bennett is used as frankincense. The unripe seeds of *Parkia Africana* R. Br. are used as an aphrodisiac and as a coffee-substitute. Several species of *Hardwickia*, of Africa and the East Indies, yield oleoresins used like *Copaiba*. The root of *Epeiua Isumani* Oliv. is used for toothache. In India, the pith of an aquatic *Æschynomene* is turned into sheets and used for paper and for various decorative purposes. Hat-bodies made from it have a peculiar power for excluding the sun.

Fully a thousand species of this great family have been recorded as of medicinal interest.

LEPTANDRA, *U. S.*—Leptandra.

Culver's root, Culver's physic, Black-root, E.; *Leptandra-Wurzel*, G.; *Racine de leptandra* or *de véronique de Virginie*, Fr.

The dried rhizome and roots of *Veronica Virginica* L. (*Leptandra V.*—Nutt.; *V. Sibirica* L.; *Leptandra purpurea* Raf.—Fam. *Scrophulariaceæ*).

Origin.—From a tall (3 to 6 Ft.) perennial herb, common and abundant in rich woodlands, in eastern and central North America, in the southern section only in the

FIG. 255.

Leptandra (½ Nat.).

elevated regions. It is well distinguished by its simple, slender stems, clothed with whorls of 4 to 6 nearly sessile, lanceolate, serrate leaves and terminal panicles of slenderly lanceolate, acute spikes of white, rarely purplish flowers, the corollas short-tubular, the 2 stamens long-exserted. The drug is collected in the autumn, and should be kept at least a year before being used.

Description.—Rhizome of oblique growth, from 10 to 15 Cm. (4 to 6 In.) long, and 4 to 8 Mm. (⅛ to ⅓ In.) thick, bent and branched, the branches similar to the main rhizome, and readily separating from it; cylindraceous, slightly flattened, dark-gray-brown or sometimes

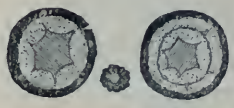
blackish, slenderly annular, bearing few cup-shaped stem-scars upon the upper surface and, upon the sides and underneath, numerous coarse, brittle roots of the same color and articu-

Fig. 256.

Leptandra (½ Nat.).

lated into saucer-shaped cavities of the rhizome; fracture tough and woody, exhibiting a thin, blackish bark, a hard, yellowish wood, and a large purplish-brown pith or partly hollow center; inodorous; taste bitter and somewhat acrid, becoming less acrid upon keeping.

Fig. 257.



Leptandra Virginica: transverse sections of rhizomes and roots.

We know of nothing which resembles Leptandra sufficiently to be mistaken for it.

Constituents.—Culver's root contains the bitter principle *leptandrin*, 6 per cent. of inert (?) resin, a little saponin, volatile oil, tannin, gum, mannit, and glucose. Leptandrin occurs in bitter, yellow or greenish needle-shaped crystals, soluble in hot water, alcohol, ether, and benzol. Exposed for a long time to the action of dilute mineral acid, or boiled with it for a short time, it loses its bitterness and a dark, resinous body is produced. Leptandrin is probably a glucoside. The alcoholic extract is the most active preparation.

Pharmaceutical Preparations.—Extract of Leptandra, Fluidextract of Leptandra, U. S. P.

Action and Uses.—In the recent state, leptandra is a violent cathartic and emetic. When dried, it is milder and more uncertain in its action. The drug is said to increase slightly the flow of bile, and to act as a stimulant to the mucous glands of the intestines. It has been employed as a substitute for mercurials, and is thought by some to be a reliable remedy in the treatment of duodenal indigestion and chronic constipation. The dose of the powdered drug as a cathartic is from 20 to 60 grains (1.3–4 Gm.). The impure resin, improperly called leptandrin, may be employed in doses of from 2 to 5 grains (0.12–0.30 Gm.).

LEVISTICUM.—Lovage.

Lavose or Levose, Sea parsley, E.; *Radix levistici*, P. G.; *Liveche*, Fr. Cod.; *Liebstockel, Badekraut, Barmutterwurz*, G.; *Ache de montagne*, Fr.

The dried rhizome and root of *Levisticum Levisticum* (L.) Lyons (*Ligusticum L.* L.; *Levisticum officinalis* Koch; *L. vulgare* Reichb.—Fam. *Umbelliferæ*).

Origin.—From a perennial, somewhat fleshy or succulent, widely branching herb, the stems ascending, with large decompound leaves on thick sheathing petioles, and bearing terminal umbels of yellow or yellowish-white flowers. It is a native of southern Europe, and is largely cultivated as a condiment and for medicinal purposes, and has become somewhat naturalized in the United States and elsewhere.

Description.—About 30 to 40 Cm. (12 to 16 In.) long, 2.5 to 3.5 Cm. (1 to 1½ In.) thick, several-headed, indistinctly annulate above, shrivelled and heavily wrinkled longitudinally, more or less branched, the branches similar but smaller, deep yellowish-brown externally, bright-yellow within; bark very thick, radiate, the outer portion fissured, exhibiting on transverse section irregular circles of orange-yellow resin-cells; wood-zone soft, with narrow medullary rays, and containing a pith in the upper portion, corresponding to that which is externally annulate and which is in reality rhizome; odor balsamic and resembling Angelica, as does the taste, though the latter is sweeter and more mucilaginous. The drug is readily mistaken for Angelica when in fragments, but is distinguished by its peculiar softness and sponginess, its yellow internal color, and the arrangement of its resin-cells.

Fig. 258.

Levisticum (½ Nat.).

Constituents.—With considerable sugar and gum, lovage contains as its important constituents a peculiar volatile oil (see Olea Destillata) and several resins possessing the general characters of the resins of its family.

Action and Uses.—Lovage has been employed as a stimulant, carminative, diuretic, and emmenagogue; and is said to be of value in the treatment of flatulent dyspepsia, dropsical effusions, and amenorrhœa. The dose in infusion (1 ounce—30 Gm.—to 1 pint—480 Cc.) is from 2 to 4 fluidrachms (4–8 Cc.).

This is the only species of the genus. Several species of the closely related genus Ligusticum will be found considered under Umbelliferæ.

LILIACEÆ.—The Lily Family.

This family, commonly regarded as comprising about 200 genera and nearly 2500 species, is, probably with good reason, divided by some modern botanists into the distinct families *Melanthaceæ*, *Convallariaceæ*, *Smilaceæ*, and *Liliaceæ* proper. For convenience, the entire group is here considered together. The family is pre-eminently ornamental, contributing a large number of the most beautiful and fragrant cultivated flowers, including the lilies, tulips, hyacinths, etc. The important food-plants onion, garlic, and asparagus are also contributed by this family. Of the 300 or so of recorded medicinal species, many will be found described under the titles Allium, Aloe, Asparagus, Colchicum, Convallaria, Sarsaparilla, Scilla, Veratrum, and Veratrina. Others of less importance are here considered. Many species, apart from those medicinally employed, are poisonous. The poisonous and medicinal constituents are of various classes, but usually glucosides, and very frequently of the saponin group.

SAPONIN GROUP.

Soap-root.—*Chlorogalum pomeridianum* (Ker.) Kunth (*Scilla p.* DC.; *Phalangium p.* Sweet; *Ornithogalum divaricatum* Lindl.) is the *Californian soap-root*, *-bulb*, or *-apple*, or *Amole*. Its large bulb, resembling that of squill, is universally used by the Indians of the regions where it grows, as a detergent and as a fish poison. It is especially valued for its stimulating effects upon the scalp. It has other uses dependent upon the action of its saponin, and it is an emetico-cathartic poison. Over the deserts of the southwestern United States and Mexico, the rhizomes of large species of Yucca are called "Soap-root," and have the same uses as those of the California variety. There is probably no better tonic or stimulant treatment for the hair than a free application of a solution of this juice in alcohol, water, or glycerin. Besides the saponin, it contains a great number of acicular raphides, which doubtless add, mechanically, to the stimulation. *Yucca filamentosa* L., of the southeastern United States, the *Adam's needle*, *Eve's thread*, *Thread-and-needle*, *Bear-grass* or *Bear-thread*, has a large rhizome which contains nearly 2 per cent. of saponin, and which is used as a stimulant, obviously due to the action of this constituent.

Trillium.—Various species of this genus, especially *T. erectum* L., of eastern and central North America, are used as uterine stimulants like Caulophyllum, under the names

Birthroot ("Bethroot" or "Bathroot"), *Wake-robin*, or *Indian shamrock*, chiefly for the action of a kind of saponin which they contain. The species named contains about 5 per cent. of this substance. All the species have a simple stem, mostly about 30 Cm. (1 Ft.) high, bearing near the summit a whorl of 3 reticulate-palmately veined and usually broad leaves. Just above these, it terminates in a single trimerous flower, which is followed by a triangular-ovoid, 3-celled, many-seeded dark-purple or red berry. *T. sessile* L., *T. viride* Beck., and *T. recurvatum* Beck. have sessile flowers, the last-named with petioled, the other two with sessile leaves, the first named with purple, the second with green flowers. In the other 5 species of the eastern United States the flower is stalked. *T. nivale* Riddell has obtuse leaves, while those of the others are acuminate. *T. undulatum* Willd. has the leaves petioled, the remaining 3 have them sessile or almost so. *T. grandiflorum* (Michx.) Salisb. (*T. rhomboideum grandiflorum* Mx.), the *Large-flowered birthroot* or *Wake robin* or *White wood lily*, has the flowers 5 to 10 Cm. (2 to 4 In.) or more broad, while those of the others are only about half as large. *T. erectum* has the flower erect and the petals flat or spreading, while *T. cernuum* L., the *Nodding wake robin*, *Cough-root*, *Ground lily*, or *White Benjamin*, has the flower recurved below the leaves and the petals also recurved. The commercial drug consists of a subglobular, oblong, or nearly obconical and oblique rhizome, which is truncate at the lower end and terminates above with a short tuft of sheathing leaf-bases; about 25–38 Mm. (1 or 1½ In.) long, 12–18 Mm. (½ to ¾ In.) in diameter, slightly flattened, finely but distinctly annulate, and, particularly in the upper portion, beset with circular rows of straw-colored or pale-brownish rootlets or with the short remnants of the same; externally of a yellowish orange-brown color, internally whitish or more frequently yellowish or light-brown, and upon transverse section seen to be composed of rather spongy parenchyma and of small scattered fibrovascular bundles, which are circular, elongated, or irregularly curved, and more numerous toward the circumference than near the center. It is inodorous or nearly so, and has a sweetish, astringent, afterward bitter and acrid taste.

Besides the saponin above referred to, Trillium contains resinous and fatty matter, much starch, apparently a little volatile oil, tannin, and coloring-matters.

T. globosum is the Chinese *Ch'ien-li-kwang*, and is in that country believed to have the effect of improving vision.

Muscari comosum Mill. (*Hyacinthus c.* L.), the *Feather hyacinth*, *Purple-* or *Purse-tassels* or *Tuzzimuzzy*, of Europe, as well as other species of *Muscari*, is used for its diuretic and stimulant properties. From the species named has been extracted *comosic acid*, which apparently acts like saponin.

Eriospermum latifolium Jaeg. (*Ornithogalum Capense* L.), of southern Africa, yields a tuber used as an emmenagogue, very much like Trillium, the action apparently due to saponin. The same is apparently true of *Limethis bicolor* Kunth, the *Cournianon* of the Mediterranean region, which is emetic and purgative.

Trillium was formerly employed by the North American Indians for the purpose of controlling uterine hemorrhage and producing uterine contractions during labor. It is said to be astringent, alterative, tonic, and sialagogue. The bruised plant has been locally applied as a stimulant to chronic ulcers. The internal dose of the dried root is stated to be 1 drachm (4 Gm.).

MISCELLANEOUS DRUGS AND POISONS.

Medeola, the *Indian cucumber* or *cucumber root*, is the rhizome of *Medeola Virginiana* L. (*Gyromia V.* Nutt.), a flocculent-woolly perennial herb with slender stem, 30 to 60 Cm. (1 to 2 Ft.) high, bearing above the middle a whorl of 6 or 8 lance-oblong leaves, which are about 7.5 Cm. (3 In.) long, a third as broad, and acute at both ends, and near the top a second whorl of half as many smaller and relatively broader ones, and terminating in 3 or 4 small trimerous, greenish-yellow, recurved flowers which are followed by small purplish-blue berries. The rhizome is horizontal, 25–38 Mm. (1 or 1½ In.) long, about 6 Mm. (¼ In.) thick, pointed at the lower end, beset with hair-like simple roots, pale brown-yellowish externally, white internally, and with a few small wood-bundles. It is without odor, and has a sweetish, in the fresh state somewhat cucumber-like, taste. Its constituents, among which is starch, have not been investigated. Nothing appears to have been added for many years to the scanty knowledge originally possessed of this drug, viz., that it was reputed to be hydragogue and diuretic, and therefore useful in dropsies.

Phormium, the *New Zealand flax* or *hemp*, or *Flax lily* (*Flachslilie, Neuseelandischer Flachs*, G.; *Lin* (or *Chanvre*) *de la Nouvelle Zelande*, Fr.), is the rhizome, roots, and leaf-bases of *Phormium tenax* Forst., of New Zealand and the neighboring islands. This is a Yucca-like plant, producing a basal tuft of linear, tough-fibrous leaves, the fiber of which is used as a flax-substitute, and a flower-stalk 4 or 5 M. (12 to 16 Ft.) long. The fleshy rhizome, roots, and leaf-bases are nsed in making a strong decoction which, with or without the addition of antiseptics, has been claimed to act in checking suppuration in wounds dressed with it.

Lilium candidum L., the *White* or *Meadow lily* of southwestern Asia, is well known in

cultivation. Its scaly bulb is employed medicinally. It has a mucilaginous, slightly bitter and nauseous taste, and contains mucilage and a slight amount of an acrid substance. It is used in uterine disorders but apparently without good reason. About a dozen other species of Lily are similarly employed.

Erythronium, Adder's-tongue, -leaf, or *-violet, Dog's-tooth violet, Trout lily, Yellow snake-leaf* or *Yellow Snowdrop,* is the plant *E. Americanum* Ker. (*E. angustatum* Raf.; *E. bracteatum* Bigel.), a very beautiful and pleasing early spring flower of eastern North America. The plant, which is very smooth, grows from a small ovoid fawn-colored corm, which is quite deeply buried in the soil and is of solid, firm consistence and white and starchy internally. The stem is slender, a few inches high, and bears near the ground a pair of oblong, dark-green, purplish-blotched leaves, and terminates in a handsome, large, pendulous, bright-yellow, trimerous, lily-like flower with the perianth-divisions strongly recurved. Its constituents have not been investigated. All parts, but especially the leaves and corm, are emetic, especially when fresh. It is mostly used in the form of a stimulating poultice, applied to swellings.

Uvularia or *Bellwort* is the rhizome of *U. perfoliata* L., a beautiful smooth herb about a foot high, the stem forking at the summit and bearing a single small, pendulous, yellow, lily-like flower from the end of one of the branches. The leaves are peculiar in the manner in which they clasp the stem at the base, whence the name *perfoliata.* The rhizome is slender, a few inches long, and sparsely provided with roots. It has a slightly acrid and mucilaginous taste somewhat similar to that of *Erythronium,* and the constituents, which have not been investigated, are probably similar. It is used for similar purposes, as well as for erysipelas, ulcerated mouth, etc. *U. latifolia* Sm. is the Chinese *Pei-mi-hiang,* or *Ming.*

Ruscus aculeatus L. (*R. flexuosus* Mill.), the *Ditch-, Sea-,* or *Tassel-grass,* or *Tassel pond-weed,* related to Asparagus, native of the Mediterranean region, is used as a diuretic, diaphoretic, and vulnerary. Its seeds are said to be used as a coffee-substitute.

Camassia esculenta Lindl., of the northwestern United States, produces a starchy bulb which is quite an important food among the Indians, and is probably capable of great improvement by cultivation. A number of species of *Asphodelus* are employed as foods, their roots being mucilaginous, like Salep. Fritillaria is a large genus, producing starchy bulbs, several of which are edible, like those of *Calochortus. F. imperialis* L., of Persia, is said to be there cultivated as a food-plant, its bulb poisonous when raw, but wholesome when cooked. *F. Indica* Spr., of the western United States, is reputed among stockmen to be a Loco-weed (see LEGUMINOSÆ). The large root-stock of *Melanthium Virginicum* L., the *Bunch-flower, Black-flower,* or *Quafodil,* of the eastern and central United States, is poisonous and is used as a parasiticide. *M. Cochin-Chinensis* Lour. (*Anguillaria C.* Spr.) is the Chinese *T'ien-men-tung,* and is there used as an anthelmintic, expectorant, etc. *Paradisia liliastrum* (L.) Bert. (*Anthericum l.* L.) is a heart poison, as is *Bulbine bulbosum* Hassk., of Australia. *Xerophyllum asphodeloides* (L.) Nutt. (*Helonias a.* L.; *H. setifolium* Michx.), of the southern United States, contains the alkaloid *xerophylline. Paris quadrifolia* L., the European *Wolfsberry* (*Einbeere,* G.), contains the poisonous glucoside *paridin* and is emetic. A number of species of *Zigadenus,* of the western United States, are intensely poisonous. *Z. venenosus* Wats., the *Death camas,* destroys great numbers of grazing animals, and is fatal to man when eaten by mistake for the *Camassia esculenta* or *Sweet camas. Chrosperma muscætoxicum* (Walt.) Kuntze (*Melanthium m.* Walt.; *Amianthium m.* Gray) is the *Fly-, Crow-,* or *Fall-poison* of the United States Atlantic coast-region. It is used as an insecticide, and is poisonous to birds.

LIMONIS CORTEX, *U. S., Br.*—Lemon Peel.

Cortex Fructus Citri, P. G.; *Flavido Corticis Citri,* P. A.; *Citronenschale, Limonenschale,* G.; *Écorce* (or *Zeste*) *de citron* (or *de limon*) Fr.; *Scorza do Limone,* It.; *Casca de Limao, Amarello da Casca de Limao,* Port.

The recently separated outer rind of the ripe fruit of *Citrus Limonum* Risso (*C. medica,* var. *B.* L.; var. *Limonum* Hook. f.—Fam. *Aurantiaceæ*).

Lemon Peel is official in nearly all pharmacopœias, though several specify the rind of the *Cedron* or *Cedrat.* The German admits only the outer portion of the rind of the fresh ripe fruit and requires that it be dried. The Russian, on the contrary, requires the retention of the white inner rind.

Origin.—A small tree, native of northwestern India and cultivated, in numerous varieties, in all tropical and subtropical countries. The different varieties vary in size and form, but are, from a medicinal point of view, identical. There is a sweet lemon, believed to be a distinct species (*C. Lumia* Risso), sometimes of gigantic size, sometimes smaller than the ordinary lemon. The Citron, Cedron, or Cedrat is the very large, lemon-like fruit used for making preserved or candied citron. It is the product of *C. medica* Risso, and is totally different in properties from either the lemon or the orange.

Various methods are employed for removing the peel. If removed in broad bands or ribbons, the removal of a considerable portion of the white inner with the oily outer layer is inevitable, and the aromatic constituents are correspondingly decreased in percentage. For this reason, *shredded* lemon peel, that removed in very narrow bands, is preferred. This product is itself, however, often deceptive, since it may be cut in an oblique direction in such a manner as to take away most or the whole of the white portion with the other.

Description.—Lemon peel forms either narrow bands or oblong and curved sections with little of a spongy, white inner layer adhering to them; the outer surface has a deep lemon-yellow color, and is somewhat uneven from numerous oil-glands imbedded in the tissue. This portion has an agreeable odor and an aromatic slightly bitter taste; it is the only part which possesses medicinal value. The Pharmacopœia now directs that the spongy white inner layer adhering to the segments, which is inodorous and nearly tasteless, should be removed before use.

Dried lemon and orange peels often closely resemble one another, and the former is frequently adulterated with the latter. Upon moistening orange peel with strong hydrochloric acid it quickly assumes a rich, dark-green color, while lemon peel is not colored, or merely becomes of a dingy yellowish-brown tint (*Clayton*). Lemon peel of poor appearance is often artificially colored to improve it.

Constituents.—Lemon peel is used wholly for the effect of its volatile oil (see Oleum Limonis). The slight bitterness is due to the same constituents as those described under Aurantii Amari Cortex. The black coloration imparted to the white layer by ferric salts is due to an undetermined constituent.

Action and Uses.—Lemon peel is a stimulant stomachic, and enters into a number of preparations to increase their efficacy and modify their taste.

LIMONIS SUCCUS, *U. S.*—Lemon Juice.

Succus limonis, Br.; *Succus Citro.*—*Limonensaft, Citronensaft*, G.; *Suc de citron* (or *de limon*), Fr.; *Succo de Limone*, It.; *Zumo de Limon*, Sp.

The freshly expressed juice of the ripe fruit of *Citrus Limonum* Risso (*C. medica*, var. *B.* L.; var. *Limonum* Hook. f.)—Fam. *Aurantiaceæ.*

Lemon juice is official in nearly all pharmacopœias. Several specify that the rind and seeds should be removed before the juice is expressed.

Origin (see Limonis Cortex).—The fruit of the lime (*C. acida* Roxb.) is very commonly substituted for lemon juice, and is in every respect its equal if not superior. It has been found far richer in citric acid. It is to be remembered that, as there is a sweet lemon, so there is a sweet lime (*C. Limetta* Risso).

Description.—A slightly turbid, yellowish liquid, usually having an odor of lemon, due to the accidental presence of some of the volatile oil of the rind. Taste acid, and often slightly bitter. Specific gravity 1.030 to 1.040 at 25° C. (77° F.). It reddens blue litmus-paper, and should contain from 7 to 9 per cent. of citric acid.

Ellwood determined the percentage of citric acid in lemon juice, collected during different months, to range from 32 to 42 grains per fluidounce. The U. S. P. demands the absence of acetic, sulphuric, and tartaric acids and sulphates, and also that at least 10 Cc. of normal potassium hydroxide solution shall be required to neutralize 10 Cc. of lemon juice, using phenolphthalein as indicator. The British Pharmacopœia allows only 3 per cent. of ash, and requires from 7 to 9 per cent. of citric acid; also that 110 minims of the juice be neutralized by about 11½ grains of potassium bicarbonate, about 9½ grains of sodium bicarbonate, or about 16½ grains of sodium carbonate.

Constituents.—Besides its 7 to 10 per cent. of citric acid, and the small amount of ash, lemon juice contains from 0.5 to 1 per cent. of gum and sugar. Witt found the principal constituents of the ash to be potash 44.34, lime 7.61, and phosphoric acid 7.56 per cent. Cossa found about 15 per cent. of phosphoric acid.

Action and Uses.—Lemon juice is an excellent refrigerant, and in the form of lemonade affords an agreeable beverage during the course of the acute febrile affections. It is largely employed, and is considered by many as a prophylactic and specific for the treatment of scurvy. Demulcent drinks are frequently flavored by the addition of lemon juice and sugar for the purpose of rendering them more palatable. It may be tried as a remedy for rheumatism, and when topically applied is said to be beneficial in the treatment of uterine hemorrhage.

LINIMENTA.—Liniments.

Embrocations, E., Fr.; *Linimente, Einreibungen*, G.

Liniments are liquid or semiliquid preparations which are intended for external use and are applied to the skin by friction. The vehicle may be oil or alcohol, or sometimes water; many are perfect solutions, others mechanical mixtures which should be well agitated before they are used; a few are of a soft solid consistence at the ordinary temperature, but become liquid when applied to the skin. The U. S. Pharmacopœia since 1880 uses cotton-seed oil in place of olive oil, formerly directed.

The so-called *drying liniments* or *medicated varnishes* consist of mucilage of tragacanth, starch, or dextrin, with egg-albumen, suitably medicated, which when applied to the skin leave a thin varnish or protective film similar to that obtained with collodion.

LINIMENTUM ACONITI, *Br.*—Liniment of Aconite.

Liniment d'aconite, Fr.; *Akonitliniment*, G.

Preparation.—Take of aconite root, in No. 40 powder, 20 ounces; camphor, 1 ounce; alcohol (90 per cent.), a sufficient quantity. Moisten the aconite with 20 fluidounces of the alcohol and set aside in a closed vessel for 3 days, occasionally agitating; transfer to a percolator, and, when the liquid ceases to pass, continue the percolation with more of the alcohol, allowing the liquid to drop into a receiver containing the camphor until 30 fluidounces of the liniment are produced.—Br.

This liniment is about two-thirds as strong as the fluidextract, and differs also from the latter in containing camphor. With proper care and manipulation the aconite root is practically exhausted by the above process.

Action and Uses.—Aconite liniment may be employed for the relief of local pain. It is especially useful in the treatment of superficial neuralgias. (See ACONITUM.)

LINIMENTUM AMMONIÆ, *U. S., Br.*—Ammonia Liniment.

Linimentum ammoniatum, P. G.; *Linimentum volatile, Linimentum ammoniacale.—Volatile liniment*, E.; *Liniment ammoniacal (volatil), Savon ammoniacal*, Fr.; *Flüchtiges Liniment, Flüchtige Salbe*, G.

Preparation.—Ammonia water, 350 Cc.; alcohol, 50 Cc.; oleic acid, 30 Cc.; cotton-seed oil, 570 Cc.; to make 1000 Cc. Mix them.—U. S.

To make a quart of official ammonia liniment, mix 11¼ fluidounces of ammonia water, 1½ fluidounces of alcohol, 1 fluidounce of oleic acid, and 18¼ fluidounces of cotton-seed oil, and shake well.

Take of solution of ammonia, 1 fluidounce; almond oil, 1 fluidounce; olive oil, 2 fluidounces. Mix together with agitation.—Br.

The German Pharmacopœia directs 3 parts of olive oil and 1 part of poppy-seed oil, and the French Codex 9 parts of expressed oil of almonds to 1 part of ammonia water. The fixed oil is partly decomposed, with the formation of an ammonia soap, by means of which the water and oil are kept well mixed, forming an opaque emulsion. Ammonia liniment may be prepared by shaking together in a bottle 3½ fluidounces of ammonia water, ½ fluidounce of alcohol, 3 fluidrachms of oleic acid, and 5⅝ fluidounces of cotton-seed oil. The addition of alcohol in the official formula is intended to preserve the fluidity of the liniment, as the latter has a tendency to thicken considerably if kept on hand for some time.

LINIMENTUM AMMONIATO-CAMPHORATUM, P. G.—*Linimentum ammoniæ camphoratum.—Camphorated volatile liniment*, E.; *Liniment ammoniacal camphré*, Fr.; *Flüchtiges Kampferliniment*, G.—The French Codex and German Pharmacopœia direct it to be made precisely like volatile liniment, except that camphor liniment is substituted for the almond and olive oil, respectively.

Uses.—This preparation is employed as a stimulant and rubefacient. As a rule it should be applied by rubbing, but if it be applied to the skin upon flannel and evaporation prevented, vesication may occur. The remedy is employed for the relief of rheumatic and neuralgic pains, and for the purpose of aborting beginning inflammations such as pharyngitis and bronchitis. If too severe in its action, it may be diluted with oil.

LINIMENTUM BELLADONNÆ, *U. S., Br.*—Belladonna Liniment.

Liniment de belladone, Fr.; *Belladonnaliniment*, G.

Preparation.—Camphor, 50 Gm.; fluidextract of belladonna root, a sufficient quantity to make 1000 Cc. Dissolve the camphor in about 800 Cc. of the fluidextract, and then add sufficient of the latter to make the product measure 1000 Cc.—U. S.

To make 1 pint of the official liniment, dissolve 365 grains of camphor in 12 ounces of fluidextract of belladonna root, and add sufficient fluidextract to bring the volume up to 16 fluidounces.

Liquid extract of belladonna, 10 fluidounces; camphor, 1 ounce; distilled water, 2 fluidounces; alcohol (90 per cent.), a sufficient quantity. Dissolve the camphor in 6 fluidounces of alcohol; add the liquid extract of belladonna, the distilled water, and sufficient alcohol to produce 20 fluidounces. Set aside for 24 hours and filter.—Br.

Owing to the difference in alkaloidal strength of the U. S. and Br. fluidextracts of belladonna, the former liniment will be about one-third stronger than the last named.

Uses.—Belladonna liniment is a useful preparation for the relief of rheumatic and neuralgic pains.

LINIMENTUM CALCIS, *U. S., Br.*—Lime Liniment.

Liniment of lime, Carron oil, E.; *Liniment calcaire, Savon calcaire*, Fr.; *Kalkliniment*, G.

Preparation.—Take of solution of lime, linseed oil, each 500 Cc. Mix them.—U. S.

Take of solution of lime, olive oil, each 2 fluidounces. Mix together, with agitation.—Br.

A lime soap is formed by this process, which keeps the excess of the oil emulsionized for a short time, the two separating together from the aqueous liquid.

The French Codex directs the separation of the soft saponaceous mass resulting from the agitation of 9 parts of lime water with 1 part of expressed oil of almonds, and its preservation for use.

Uses.—Carron oil when thickly spread upon lint or cotton forms an efficient application for the treatment of recent burns or scalds. It should be frequently renewed in order to prevent the dressings from adhering to the burned area.

LINIMENTUM CAMPHORÆ, *U. S., Br.*—Camphor Liniment.

Oleum camphoratum, P. G.; *Linimentum camphoratum.—Camphorated oil*, E.; *Liniment camphré, Huile camphré*, Fr.; *Kampherliniment*, G.

Preparation.—Take of camphor, in coarse powder, 200 Gm.; cotton-seed oil, 800 Gm.; to make 1000 Gm. Introduce the camphor and the cotton-seed oil into a suitable flask, and apply a gentle heat, by means of a water-bath, loosely stoppering the flask during the operation. Agitate from time to time, until the camphor is dissolved.—U. S.

To make about 1 pint of camphor liniment, dissolve 2 avoirdupois ounces of camphor in 14½ fluidounces of cotton-seed oil.

Take of camphor, 1 ounce; olive oil, 4 fluidounces. Dissolve the camphor in the oil.—Br.

Dissolve camphor 1 part in olive oil, 9 parts.—Fr. Cod., P. G. Oleum Camphoratum Forte of the German Pharmacopœia contains twice as much camphor as the preceding.

A simple solution of camphor in oil, which is best obtained by employing the camphor as a fine powder or by digesting the mixture in a closed bottle at a moderate heat.

Souley's *Carbolized Camphor Liniment* is made by dissolving pure carbolic acid 9 parts and camphor 25 parts in absolute alcohol 9 parts and adding oil 35 parts.

Uses.—Camphor liniment may be employed for the relief of sprains, bruises, and rheumatic pains, and as a mild counterirritant in bronchitis, especially of children. As an absorbent it has been successful when applied to glandular enlargements.

LINIMENTUM CAMPHORÆ AMMONIATUM, *Br.*—Ammoniated Liniment of Camphor.

Linimentum camphoræ compositum.—Compound camphor liniment, E.; *Liniment ammoniacal camphré anglais*, Fr.; *Ammoniak- und Kampherliniment*, G.

Preparation.—Take of camphor, 2½ ounces; oil of lavender, 1 fluidrachm; strong solution of ammonia, 5 fluidounces; alcohol (90 per cent.), a sufficient quantity. Dis-

solve the camphor and oil of lavender in 12 fluidounces of alcohol; add the strong solution of ammonia gradually, shaking them together, until after adding sufficient alcohol to produce 20 fluidounces of the liniment a clear solution is formed.—Br.

Uses.—This preparation combines the properties of both a rubefacient and an anodyne. It may be used for the relief of rheumatic and neuralgic pains.

LINIMENTUM CHLOROFORMI, *U. S., Br.*—Chloroform Liniment.

Liniment au chloroforme, Fr.; *Chloroformliniment*, G.

Preparation.—Take of chloroform, 300 Cc.; soap liniment, 700 Cc.; to make 1000 Cc. Mix them.—U. S.

Take of chloroform, liniment of camphor, each 2 fluidounces. Mix.—Br.

Chloroform 1 part, expressed oil of almond 9 parts.—Fr. Cod.

The preparations bearing the same name in the three pharmacopœias differ essentially in composition as well as in the proportion of chloroform.

Uses.—Chloroform liniment forms an efficient local application for the relief of many painful affections. Its full anodyne effect can only be obtained by preventing the evaporation of the chloroform. This may be accomplished by the use of oiled silk or waxed paper.

Allied Preparation.—Linimentum Aconiti et Chloroformi, *Liniment of Aconite and Chloroform*, N. F.—Tincture of aconite, 125 Cc.; chloroform, 125 Cc.; soap liniment, 750 Cc. Mix. This liniment is largely used under the name of Compound Chloroform Liniment.

LINIMENTUM CROTONIS, *Br.*—Liniment of Croton Oil.

Linimentum tiglii, N. F.—*Liniment crotoné*, Fr.; *Krotonöllinimeut*, G.

Preparation.—Take of croton oil, 1 fluidounce; oil of cajuput, alcohol, 90 per cent., each 3½ fluidounces. Mix.—Br.

Croton oil, 12 Cc.; oil of cajuput, 44 Cc.; alcohol, 44 Cc. Mix.—N. F.

This is simply a solution of croton oil in alcohol and oil of cajuput, and has the odor of the latter.

Uses.—This preparation is an active rubefacient and counterirritant, producing pustulation in a short time. From 20 to 30 minims (1.3–2 Cc.) may be rubbed upon a limited area and repeated at intervals of 8 hours until pustulation takes place, when its use should be stopped.

LINIMENTUM HYDRARGYRI, *Br.*—Liniment of Mercury.

Linimentum mercuriale.—Liniment mercuriel, Fr.; *Quecksilberliniment*, G.

Preparation.—Take of ointment of mercury, 1 ounce; strong solution of ammonia, 160 minims; liniment of camphor, a sufficient quantity. Add the strong solution of ammonia to sufficient liniment of camphor to produce 1½ fluidounces; triturate the ointment of mercury with sufficient liniment of camphor to produce 1½ fluidounces; mix the two liquids.—Br.

Uses.—Mercury liniment may be employed to promote the absorption of fluids, and to aid in the resolution of syphilitic tumors and chronic enlargements of joints and glands. Care should be exercised in its employment as it frequently produces salivation.

LINIMENTUM OPII, *Br.*—Liniment of Opium.

Anodyne liniment, E.; *Liniment opiacé*, Fr.; *Opiumliniment*, G.

Preparation.—Take of tincture of opium, soap liniment, each 2 fluidounces. Mix.—Br.

The *Liniment savonneux opiacé* of the French Codex was made by triturating 5 parts of powdered soap with 90 parts of expressed oil of almonds, and adding 5 parts of tincture of opium; it must be well agitated.

Uses.—Opium liniment may be used as an anodyne for the relief of sprains and rheumatic pains.

LINIMENTUM POTASSII IODIDI CUM SAPONE, *Br.*—Liniment of Potassium Iodide and Soap.

Liniment savonneux ioduré, Fr.; *Jodkalium-Seifenliniment*, G.

Preparation.—Take of curd soap, cut small, 2 ounces; potassium iodide, 1½ ounces; glycerin, 1 fluidounce; oil of lemon, 1 fluidrachm; distilled water, 10 fluidounces. Reduce the soap to fine shreds, and mix this with the water and glycerin in a porcelain dish over a water-bath. When the soap is dissolved, pour the liquid into a mortar in which the potassium iodide has previously been powdered. Mix briskly, and continue the trituration until the mixture is solid. Set aside for an hour; then rub well the oil of lemon into the cream-like product.—Br.

Uses.—This liniment is intended to be employed in conjunction with massage for the purpose of producing the systemic effect of the iodide.

LINIMENTUM SAPONIS, *U. S., Br.*—Soap Liniment.

Spiritus nervinus camphoratus; Liquid opodeldoc, E.; *Liniment savonneux camphré*, Fr.; *Flüssiger Opodeldok*, G.

Preparation.—Soap, dried and granulated, 60 Gm.; camphor, in small pieces, 45 Gm.; oil of rosemary, 10 Cc.; alcohol, 725 Cc.; water, a sufficient quantity to make 1000 Cc. Add the soap to 200 Cc. of boiling water, heat the mixture on a water-bath until a clear gelatinous mass results. Mix this, while yet warm, with 500 Cc. of alcohol, and stir it until solution is effected. Dissolve the camphor and oil of rosemary in 225 Cc. of alcohol by agitation in a bottle; add this solution to the warm soap mixture; mix thoroughly, and, if necessary, add enough water to make the product measure 1000 Cc. Set it aside in a cool place for 24 hours, then filter.—U. S.

To prepare 2 pints of soap liniment will require granulated dried soap, 885 grains, camphor 663 grains, oil of rosemary 154 minims, alcohol 24 fluidounces, and sufficient water to make the solution measure 32 fluidounces.

Take of soft soap, 2 ounces; camphor, 1 ounce; oil of rosemary, 3 fluidrachms; alcohol (90 per cent.), 16 fluidounces; distilled water, 4 fluidounces. Dissolve the soap in the distilled water; dissolve the camphor and oil of rosemary in the alcohol; mix the solutions; set aside for one week and filter.—Br.

The U. S. P. directions for making soap liniment are a great improvement over those of the last pharmacopœia, and a perfect solution can be effected in comparatively short time. The object of setting the liniment aside in a cool place for 24 hours, is to get rid of the sodium palmitate always present in Castile soap, and which is but sparingly soluble in the menstruum when cold. Since the Br. formula directs the use of soft soap, separation will not occur in the cold, potassium soap being soluble in alcohol cold or warm.

Uses.—Soap liniment is a mild anodyne and absorbent, but is principally used as a vehicle for other remedies.

Allied Preparations.—Linimentum Saponato-Camphoratum, P. G.—*Camphorated soap liniment, Solid opodeldoc*, E.; *Opodeldok*, G.—Medicinal soap, 40 parts; camphor, 10 parts; alcohol, 420 parts; oil of thyme, 2 parts; oil of rosemary, 3 parts; ammonia water, 25 parts. Dissolve the soap and camphor in the alcohol with the aid of a gentle heat, and filter the solution while still warm; add the oils of thyme and rosemary, and finally the ammonia water. Cool the mixture quickly.—P. G.

This preparation is practically identical with that of the National Formulary, the chief difference being that the latter directs a little more camphor and the use of stronger ammonia water in place of the 10 per cent. solution. Solid opodeldoc is better known as Steer's Opodeldoc, and is usually put up in wide-mouth vials, which are filled while the solution is still warm and fluid. It is white or yellowish in color, opalescent, and somewhat translucent, and readily liquefies at the temperature of the body.

LINIMENTUM SAPONIS MOLLIS, *U. S.*—Liniment of Soft Soap.

Tinctura saponis viridis, U. S., 1880. *Spiritus saponis kalinus Hebra.—Teinture de savon vert*, Fr.; *Hebra's Seifenspiritus*, G.

Preparation.—Soft soap, 650 Gm.; oil of lavender, 20 Cc.; alcohol, a sufficient quantity to make 1000 Cc. Mix the oil of lavender with 300 Cc. of alcohol, dissolve in

this the soft soap by stirring or agitation, and set the solution aside for 24 hours. Then filter it through paper, and pass sufficient alcohol through the filter to make the product measure 1000 Cc.—U. S.

To make 1 pint of liniment of soft soap will require soft soap $10\frac{3}{4}$ avoirdupois ounces, oil of lavender 3 fluidrachms, and alcohol sufficient to make the solution measure 16 fluidounces.

Uses.—Liniment of soft soap has been employed as a local remedy for chronic skin affections, such as psoriasis, lichen, and prurigo.

LINIMENTUM SINAPIS, *Br.*—Liniment of Mustard.

Liniment sinapisé, Fr.; *Senfliniment*, G.

Preparation.—Volatile oil of mustard, $1\frac{1}{2}$ fluidrachms; camphor, 120 grains; castor oil, 5 fluidrachms; alcohol (90 per cent.), 4 fluidounces. Dissolve the camphor in the alcohol; add the oil of mustard and castor oil. Mix.—Br.

The solution is readily effected by agitation in a vial.

The Compound Liniment of Mustard (*Linimentum Sinapis Compositum*), of the U. S. P. 1890, was made by dissolving camphor 60 Gm. in alcohol 500 Cc.; then adding to this solution fluid extract of mezereum 200 Cc., volatile oil of mustard 30 Cc., and castor oil 150 Cc., and finally sufficient alcohol to make the product measure 1000 Cc.

Uses.—This liniment is a powerful rubefacient and counterirritant, and affords a convenient method for applying volatile oil of mustard. It may be employed as a substitute for mustard plaster. Its uses are described under SINAPIS (which see).

LINIMENTUM TEREBINTHINÆ, *U. S., Br.*—Turpentine Liniment.

Linimentum terebinthinatum.—Liniment térébenthiné, Fr.; *Terpentinliniment*, G.

Preparation.—Resin cerate, 650 Gm.; oil of turpentine, 350 Gm.; to make 1000 Gm. Add the oil to the cerate, previously melted, and mix them thoroughly. —U. S.

Take of soft soap, 2 ounces; camphor, 1 ounce; oil of turpentine, 13 fluidounces; distilled water, 5 fluidounces, or a sufficient quantity. Mix the soft soap with 2 fluidounces of distilled water; dissolve the camphor in the oil of turpentine; gradually add the latter solution to the former, triturating until the mixture becomes a thick, creamy emulsion; lastly mix with sufficient distilled water to produce 20 fluidounces.—Br.

The first formula yields what is known as *Kentish liniment;* the cerate should be melted at a low heat, and then the oil gradually added, with continued stirring. The second process is a considerable modification of the first.

Uses.—Linimentum terebinthinæ is not frequently employed at the present time. It may be applied as a soothing and protective dressing to burns and scalds, and is considered by some as an efficient remedy in the treatment of superficial erysipelas and frost-bite.

LINIMENTUM TEREBINTHINÆ ACETICUM, *Br.*—Liniment of Turpentine and Acetic Acid.

Linimentum album.—Acetic turpentine liniment, Stokes' Liniment, St. John Long's Liniment, E.; *Liniment térébenthiné acetique*, Fr.; *Terpentin- und Essigliniment*, G.

Preparation.—Take of oil of turpentine, 4 fluidounces; glacial acetic acid, 1 ounce; liniment of camphor, 4 fluidounces. Mix.—Br.

The National Formulary gives the following directions: Oil of turpentine, 100 Cc.; fresh egg, albumen and yolk, 1; oil of lemon, 4 Cc.; acetic acid (36 per cent.), 20 Cc.; rose-water, 85 Cc. Triturate or beat the contents of the fresh egg with the oil of turpentine and the oil of lemon in a mortar until they are thoroughly mixed. Then incorporate the acetic acid and rose-water. Shake the mixture whenever any of it is to be dispensed.

The latter preparation, which differs materially from the former, is extensively used in this country, especially by the laity. If properly made, it will not separate, and increases in whiteness as it becomes older. The use of oil of lemon is quite superfluous, since its odor is masked by that of the oil of turpentine, and the albumen of the egg can be reduced to one-half with decided benefit. It will be found advantageous to pour the

oil and egg mixture into a bottle and add the water and acid mixture in divided portions, shaking well after each addition until a thick, creamy emulsion is formed.

Uses.—This preparation has been largely employed in the past as a stimulating liniment in the treatment of chronic rheumatic complaints. At present it is rarely prescribed by the medical profession.

LINUM, *U. S., Br.*—Flaxseed.

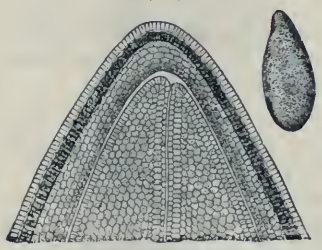
Semen Lini, P. G.; *Linseed*, E.; *Leinsamen, Flachssamen*, G.; *Semence (Graine) de lin*, Fr.; *Linaza*, Sp.; *Linhaca, Sementes de Linho*, Port.; *Semi di Lino*, It.

The ripe seed of *Linum usitatissimum* L. (*L. sativum* Blackw.)—Fam. *Linaceæ*.

Linum is official in all pharmacopœias, several of which require that it be renewed annually.

Origin.—From a slender annual of cultivation, about 2 feet high, little if at all branched, with alternate, exstipulate, linear-lanceolate leaves, and regular and symmetrical 5-merous blue flowers. The 5-celled or imperfectly 10-celled capsule contains 10 seeds. The original home of the flax is uncertain, but is probably the Mediterranean basin. It is cultivated in nearly all temperate and in some tropical regions, and is everywhere naturalized. Cultivation has developed a number of strong forms sometimes regarded as species. The principal source of flax and flaxseed is Russia.

Fig. 259.



Flaxseed, and transverse section near edge (× 65).

Description.—From 4 to 6 Mm. ($\frac{1}{6}$ to $\frac{1}{4}$ In.) long and a little more than half as broad, ovate, obtusely and obliquely pointed, flattened, the edges subacute, the base rounded; anatropous, the hilum and micropyle upon one edge, near the point; light-brown to dark-brown, smooth and shining, finely pitted under a strong lens. Structurally, the thickish testa possesses a layer of gum-cells, forming an abundance of mucilage under the action of water; the kernel consists of 2 white or yellowish oily cotyledons enclosed in a very thin perisperm. The odor should be none, or very faint; the testa bland, oily, and mucilaginous.

Ground flaxseed should be recently prepared, of a gray-brown color, yielding to carbon disulphide not less than 30 per cent. of fixed oil, the oil readily saponifiable, free from starch and fibre, and of but slight and not rancid or unpleasant odor. If 0.1 Gm. of ground linseed be mixed with 20 Cc. of water and the mixture heated to boiling, then cooled and diluted with cold water to 100 Cc., the addition of 0.5 Cc. of iodine test-solution should not produce more than a pale-blue color (limit of starch). By exposure to heat, light, and a damp atmosphere, or otherwise carelessly preserved, flaxseed, especially when ground, is apt to become rancid and foul-smelling. It is also subject to insect attack. It is generally regarded as unfit for use after the lapse of more than a year.

Constituents.—The seeds contain fixed oil, wax, resin, tannin, gum, gluten, and albumen. Only the young seeds are said to contain starch. The integuments contain much gum ($C_{12}H_{20}O_{10}$), about 15 per cent. of the seed, which swells with water to make a viscid, odorless, and almost tasteless mucilage, which is precipitated by alcohol and lead subacetate, but not by tannin. Dilute acids split it into gum, sugar, and cellulose, and, boiled with nitric acid, it yields *mucic acid*. Analyses of seeds from different sources (Dey and Cowil, 1895) gave the following yields of oil: English, 29.5; Dutch, 34.5; Turkish, 36.5; Canadian (also contained starch), 27; Russian (also contained starch), 39; South American, 39.5; and Bombay, 40 per cent. The ash amounted to from 2 to 4 per cent. The young plant yields a glucoside, *linamarin*, in odorless, bitter colorless needles, soluble in water and alcohol, but not in ether, and with dilute acids decomposed into sugar, hydrocyanic acid, and a volatile acetone. A ferment (zymase), contained in linseed meal, is said to cause the same decomposition.

Varieties and Adulterants.—In commerce, a number of geographical varieties of flaxseed are recognized, but, aside from the presence of impurities, there is no great difference in their qualities. The tropical varieties are usually larger and paler, and are less highly esteemed. To a certain extent the source can be determined by the accompanying weed-seeds.

Damaged flour and other starchy material is often introduced in grinding, and is at once detected by the microscope or the iodine test. The commonest sophistication is the

substitution, in whole or in part, of the linseed meal used as cattle-food, made by grinding up the linseed cake (*Placentis Seminæ Lini*) left after expression of the oil. This is detected by the less oily appearance of the mass and by the reduced percentage-yield of oil (less than 25 per cent.). To restore the appearance, mineral oil has been then added, but its saponification properties are thus lost or impaired.

In commerce, the percentage of impurities is roughly determined by shaking in a conical muslin bag, the impurities settling into the point. Foreign seeds and earthy impurities should not exceed 2 or 3 per cent., and are often less than 1 per cent. Occasionally they amount to 25 per cent. or more. Such seeds consist chiefly of mustard and rape and their relatives. By imperfect cleansing, sand and small stones are often present.

Actions and Uses.—Infusions of flaxseed are used as demulcents in cases of acute inflammation of the gastro-intestinal tract. They act as soothing agents, and by forming a protective coating over the mucous membrane tend to prevent farther irritation. They have also been recommended in acute bronchitis and cystitis, and in inflammatory conditions of the entire genito-urinary tract; but their value in these conditions is probably limited. An infusion made by macerating 3 drachms of flaxseed and 30 grains of extract of licorice with 10 ounces of boiling water, to which has been added a small quantity of lemon juice and sugar, is the most palatable form of administration. Flaxseed meal moistened with boiling water was formerly employed as a poultice, but is now almost entirely supplanted by hot antiseptic fomentations.

Allied Plants.—The genus *Linum*, L., contains nearly a hundred species, and several of them possess distinct properties. The herbage of *L. catharticum* L. (*Cathartolinum pratense* Reichb.), of Europe, is used as a purgative. *L. Chamissonis* Schied. (*L. aquilinum* Mol.), of Chile, is there employed under the names *Ratamilla* and *Yanga* as a stomachic and febrifuge, as are *L. ramossissimum* Gay and *L. selaginoides* Lam., of the same region. The root and bark of the related *Hugonia Mystax* L., of India, are employed as an anthelmintic, diuretic, and diaphoretic.

LIQUOR ACIDI ARSENOSI, *U. S.*—Solution of Arsenous Acid.

Liquor arsenici hydrochloricus, Br.; *Liquor arsenici chloridi*, U. S., 1870; *Hydrochloric solution of arsenic*, E.; *Liqueur arsénicale hydrochlorique*, Fr.; *Chlorarsenik-lösung*, G.

Preparation.—Arsenic trioxide, in small pieces, 10 Gm.; diluted hydrochloric acid, 50 Cc.; distilled water, a sufficient quantity to make 1000 Cc. Boil the arsenic trioxide with the hydrochloric acid and 250 Cc. of distilled water until solution has been effected. Filter the liquid, and pass sufficient distilled water through the filter to make the solution measure 1000 Cc.—U. S.

To make 1 pint of the official solution of arsenous acid, boil 73 grains of arsenic trioxide and 384 minims of diluted hydrochloric acid with 4 ounces of distilled water until dissolved; filter and add sufficient distilled water to make 16 fluidounces.

The solution of the Br. P. is identical with the above, except that 12½ Cc. of hydrochloric acid are directed in place of 50 Cc. of diluted hydrochloric acid, the latter being equal to about 14.3 Cc. of the stronger acid.

The hydrochloric acid simply facilitates solution of the arsenic trioxide in water, whereby the latter is converted into arsenous acid, thus: $As_2O_3 + 3H_2O = 2H_3AsO_3$, and does not enter into chemical reaction with it. Hence the solution contains simply the two acids, and the name solution of arsenic chloride, formerly used, was wrongly applied, since arsenous chloride, As_2Cl_6, is at once decomposed in contact with water.

Properties.—The solution is colorless, has an acid reaction and an acidulous taste. Hydrogen sulphide yields at once a bright-yellow precipitate of arsenic sulphide. In arsenic strength it corresponds with Fowler's Solution, containing 1 per cent. of arsenous acid, or 4.56 grains to the fluidounce, or 4.35 grains to the Imperial fluidounce; Valangin's Solution contained 0.38 per cent. of arsenous acid, or 1¾ grains to the fluidounce.

The strength is determined as follows: If to 24.6 Cc. of solution of arsenous acid 2 Gm. of sodium bicarbonate and 100 Cc. of water be added, and mixed with a little starch test-solution, it should require not less than 50 Cc. of tenth-normal iodine volumetric solution until the blue tint of iodide of starch makes its appearance (corresponding to 1 Gm. of arsenic trioxide in 100 Cc. of the solution.—U. S. 25 Cc. diluted with

water should discharge the color of 50.8 to 50.9 Cc. of volumetric solution of iodine, the presence of a slight excess of sodium bicarbonate being maintained throughout the operation.—Br.

Action and Uses.—This preparation may be employed for the same purpose as Fowler's Solution. It has no apparent advantage over the latter remedy. The beginning dose is from 2 to 5 minims (0.10–0.30 Cc.), largely diluted with water.

LIQUOR ACIDI CHROMICI, *Br.*—Solution of Chromic Acid.

Soluté d'acide chromique, Fr.; *Chromsäurelösung*, G.

An aqueous solution containing the equivalent of 25 per cent. of chromic anhydride, CrO_3, or 29.5 per cent. of chromic acid, H_2CrO_4.

Preparation.—Chromic anhydride, 25 Gm.; distilled water, 75 Cc. Dissolve.—Br.

Properties.—Solution of chromic acid is an orange-red liquid, without odor, and having a caustic, strongly acid character. Its specific gravity is 1.185.

Chromic acid should be weighed in glass or porcelain vessels and all contact with organic matter carefully avoided. The solution should be preserved in glass-stoppered bottles.

Action and Uses.—The employment of this solution is described under CHROMII TRIOXIDUM (which see).

LIQUOR AMMONII ACETATIS, *U. S.*, *Br.*—Solution of Ammonium Acetate.

Liquor ammonii acetici, P. G.; *Spiritus Mindereri.—Spirit of Mindererus*, E.; *Acétate d'ammoniaque liquide, Esprit de Mindérérus*, Fr.; *Ammoniumacetatlösung*, G.

An aqueous solution of ammonium acetate, containing not less than 7 per cent. of the salt, together with small amounts of acetic and carbonic acids.

Preparation.—Ammonium carbonate, 5 Gm.; diluted acetic acid, 100 Cc. Add the ammonium carbonate (which should be in translucent pieces, free from white pulverulent bicarbonate) gradually to the cold diluted acetic acid, and stir until it is dissolved. This preparation should be freshly made when wanted.—U. S.

Each fluidounce of diluted acetic acid, U. S. P., would require about 23 grains (22.84) of official ammonium carbonate in the preparation of Spirit of Mindererus, as directed above.

The solution of the Br. P. is of about the same strength, but prepared in a different manner. 50 Gm. of ammonium carbonate are dissolved in 500 Gm. of distilled water, neutralized with acetic acid, and sufficient distilled water added to make the solution measure 1000 Cc.

The official formula insures a definite amount of ammonium acetate, together with an excess of acetic acid; in following the pharmacopœial directions the dispenser will be sure that no excess of alkali can possibly be present. The 100 Cc. of diluted acetic acid ordered in the above formula contain 6.048+ Gm. of absolute acetic acid, of which 5.728+ Gm. will be required to neutralize the 5 Gm. of official ammonium carbonate (consisting of ammonium acid carbonate and carbamate), as may be seen from the equation $NH_4HCO_3NH_4NH_2CO_2 + 3HC_2H_3O_2 = 3NH_4C_2H_3O_2 + H_2O + 2CO_2$ — 156.01 : 178.74 : : 5 : x, $x = 5.728+$.

Solution of ammonium acetate should never be kept on hand for dispensing purposes, as it absorbs ammonia from the air, and finally acquires an alkaline reaction.

Properties.—It is a "clear colorless liquid, free from empyreuma, of a mildly saline taste and acid reaction. It is wholly volatilized by heat. When heated with potassium hydroxide it evolves vapors of ammonia. If to 5 Cc. of the solution 1 Cc. each of sulphuric acid and alcohol be added, and the mixture boiled, the odor of ethyl acetate will be developed.—U. S.

Action and Uses.—Solution of ammonium acetate is employed as a diuretic and diaphoretic. When given internally, it is of value in the early stages of acute tonsillitis, acute bronchitis, and in the exanthematous diseases where the eruption is delayed. It is also said to be of value in the treatment of epidemic influenza, menstrual disorders, acute alcoholic intoxication, and chronic skin affections. It has been employed as a

lotion in the treatment of bruises, beginning abscesses, glandular enlargements, and impetigo capitis. The internal dose of the U. S. P. preparation is from 4 to 8 fluidrachms (16–30 Cc.). The British preparation may be given in practically the same dose.

LIQUOR AMMONII CITRATIS, *Br.*—Solution of Ammonium Citrate.

Citrate d'ammoniaque liquide, Fr.; *Ammoniumcitratlösung*, G.

Preparation.—Ammonium carbonate, 1¾ ounces or 87.5 Gm.; citric acid, 2½ ounces, or 125 Gm.; distilled water, a sufficient quantity. Dissolve the citric acid in 5 times its weight of distilled water; neutralize with ammonium carbonate, and sufficient distilled water to produce 1 Imperial pint or 1000 Cc.—Br.

This solution contains about 72 grains of ammonium citrate in each fluidounce. It should be preserved in green-glass bottles, to avoid solution of the lead contained in flint glassware.

Action and Uses.—This preparation possesses the same properties and uses as Liquor Ammonii Acetatis. The dose is from 4 to 8 fluidrachms (16–30 Cc.).

LIQUOR ANTISEPTICUS, *U. S.*—Antiseptic Solution.

Liqueur Antiseptique, Fr.; *Antiseptische Lösung*, G.

Preparation.—Boric acid, 20 Gm.; benzoic acid, 1 Gm.; thymol, 1 Gm.; eucalyptol, 0.25 Cc.; oil of peppermint, 0.50 Cc.; oil of gaultheria, 0.25 Cc.; oil of thyme, 0.10 Cc.; alcohol, 250 Cc.; purified talc, 20 Gm.; water, a sufficient quantity to make 1000 Cc. Dissolve the boric acid in 700 Cc. of water, and the benzoic acid in 150 Cc. of alcohol, and pour the aqueous solution into the alcoholic solution. Then dissolve, in a mortar, the thymol in the eucalyptol and oils of peppermint, gaultheria and thyme; thoroughly incorporate the purified talc, and add, with constant trituration, the solution first prepared. Allow the mixture to stand, with occasional agitation, during 48 hours, filter, add 100 Cc. of alcohol to the clear filtrate, and a sufficient quantity of water to make the finished product measure 1000 Cc.—U. S.

To make a pint of the official antiseptic solution, 155 grains of boric acid should be dissolved in 11½ ounces of water, and 7 grains of benzoic acid in 2½ ounces of alcohol, and the two liquids then mixed. After dissolving 7 grains of thymol in a mixture of 8 drops of oil of peppermint, 4 drops each of eucalyptol and oil of gaultheria, and 1 drop of oil of thyme, triturate with 155 grains of purified talc, and add the solution of benzoic and boric acids. Shake occasionally during 48 hours, filter, and add to the clear filtrate first 1½ ounces of alcohol, and then sufficient water to bring the volume up to 1 pint.

Antiseptic solution prepared by the above formula is a colorless liquid, having a pleasant odor, which improves after the solution has stood for some time. When freshly made the odor of oil of peppermint predominates, but is gradually blended with that of the oil of wintergreen and the eucalyptol and thymol.

Action and Uses.—This is a mildly antiseptic solution with an agreeable odor and taste, and may be employed as a substitute of many proprietary preparations possessing a similar formula. Diluted with from 2 to 8 parts of water it is used as a general antiseptic, and is particularly serviceable in inflammations of the mouth, throat, ear, and nose.

It is extensively employed as a dentifrice.

In the treatment of pelvic inflammatory diseases of women, the solution may be applied both as a douche, in the strength of 1 to 2 tablespoonfuls (16–30 Cc.) to the pint (480 Cc.) of hot water, and by means of a tampon saturated with a mixture of 1 part of the solution with 4 parts of glycerin. In the dose of from ½ to 2 drachms (2–8 Cc.), it is administered internally to arrest decomposition of the contents of the stomach and intestines.

LIQUOR ARSENI ET HYDRARGYRI IODIDI, *U. S., Br.*—Solution of Arsenous and Mercuric Iodide.

Solutio Donovani.—Donovan's Solution, E.; *Soluté d'iodo-arsénite de mercure, Liqueur de Donovan*, Fr.; *Jodquecksilber-Arseniklösung, Donovansche Tropfen*, G.

Preparation.—Arsenous iodide, 10 Gm.; red mercuric iodide, 10 Gm.; distilled

water, a sufficient quantity, to make 1000 Cc. Triturate the iodides with 150 Cc. of distilled water until they are dissolved. Filter the liquid, and pass sufficient distilled water through the filter to make the solution measure 1000 Cc.—U. S.

The Br. P. preparation is of exactly the same strength as the preceding.

A fluidounce of Donovan's Solution contains 4.56 grains each of arsenous iodide and red mercuric iodide; the liquid should be kept in a dark place, and should not be dispensed if the color has changed to yellowish-red and the odor of iodine become apparent.

This is a solution of the two iodides in very nearly the proportion of their molecular weights, and containing them mixed, but not chemically combined.

Properties.—It is a clear, colorless, or pale-yellowish liquid, has a metallic taste, and gives precipitates with solutions of silver, alkalies, and salts of the alkaloids.

Action and Uses.—Donovan's Solution is employed as an alterative. It is thought by some to cause the speedy resolution of skin lesions occurring in advanced syphilis, and to afford relief from the night pains resulting from the same disease. It has also been employed in the treatment of many chronic skin affections, such as lupus, lepra, psoriasis, and impetigo. The beginning dose is from 1 to 5 minims (0.05–0.3 Cc.), well diluted with water.

LIQUOR ATROPINÆ SULPHATIS, *Br.*—Solution of Atropine Sulphate.

Soluté de sulfate d'atropine, Fr.; *Schwefelsaure Atropinlösung*, G.

Preparation.—Take of atropine sulphate, 17½ grains; salicylic acid, 2 grains; distilled water, 4 fluidounces. Dissolve the atropine sulphate and salicylic acid in sufficient boiled and cooled distilled water to produce 4 fluidounces of solution.—Br.

110 minims of this solution contain 1 grain of atropine sulphate.

Action and Uses.—The uses of this preparation are fully described under ATROPINE (which see). The internal dose is from 1 to 2 minims (0.05–0.10 Cc.).

LIQUOR BISMUTHI ET AMMONII CITRATIS, *Br.*—Solution of Bismuth and Ammonium Citrate.

Liquor bismuthi.—Solution of bismuth, Liquid bismuth, E.; *Soluté de citrate de bismuth ammoniacal*, Fr.; *Wismuth-Ammoniakcitratlösung*, G.

Preparation.—Bismuth oxynitrate, 613 grains; potassium citrate, 613 grains; potassium carbonate, 175 grains; nitric acid, 1 fluidounce; solution of ammonia and distilled water, of each, a sufficient quantity. Dissolve the bismuth oxynitrate in the nitric acid diluted with an equal volume of distilled water; add distilled water with constant stirring until the liquid is very faintly opalescent; add the potassium citrate and carbonate dissolved in a little distilled water; heat the liquid to the boiling-point; cool; separate the precipitate; wash it with distilled water until free from nitrates. Gradually add solution of ammonia to the moist precipitate until it is just dissolved; dilute with distilled water to 1 pint. Filter.—Br.

This preparation is described as a colorless solution of alkaline reaction, and having a specific gravity of 1.070. It has a slightly metallic taste, is freely soluble in water, and yields a white precipitate upon addition of alkalies. When heated with the latter, ammonia is evolved. Each fluidrachm represents 3 grains of bismuth oxide.

Tests.—Evaporated to dryness and the product ignited, a residue with a yellow edge results, which, when suitably treated, should not yield any reaction characteristic of silver, lead, copper, arsenic, iron, selenium, or tellurium. If 10 Cc. of the solution be mixed with 40 Cc. of water and treated with hydrogen sulphide in excess, a black precipitate is obtained, which, when washed and dried, should weigh at least 0.55 Gm. —Br.

The reactions involved in making the above solution are the formation of normal bismuth nitrate, which is subsequently decomposed by the potassium citrate, forming bismuthous citrate and potassium nitrate, potassium carbonate being added to neutralize the excess of nitric acid present. The insoluble bismuth citrate is finally brought into solution by means of ammonia water. The exact character of the compound in the finished product is an open question, some authorities contending that the ammonia liberates bismuthous hydroxide, which is kept in solution by aid of the newly formed ammonium

citrate, while others assert that a compound having the composition $BiC_6H_5O_7NH_3$ is formed.

Action and Uses.—This solution is employed as an astringent in the treatment of diarrhœa resulting from a relaxed condition of the mucous membrane of the bowel. It should not be used if any irritation is present. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

LIQUOR CALCIS, *U. S., Br.*—Solution of Calcium Hydroxide; Lime Water.

Aqua calcariæ, P. G.; *Aqua calcariæ ustæ, Aqua calcis, Calcaria soluta.—Solution of lime*, E.; *Eau (Liqueur) de chaux*, Fr.; *Kalkwasser*, G.

A saturated aqueous solution of calcium hydroxide ($Ca(OH)_2 = 73.56$), containing not less than 0.14 per cent. of the pure hydroxide.

The percentage of calcium hydroxide varies with the temperature, being somewhat over 0.17 per cent. at 15° C. (59° F.), and diminishing as the temperature rises.

Preparation.—Lime, 12 Gm.; distilled water, a sufficient quantity. Slake the lime by the gradual addition of 70 Cc. of the water, then add 360 Cc. of water, and stir occasionally during half an hour. Allow the mixture to settle, decant the liquid, and throw this away. Now add to the residue 3600 Cc. of distilled water, stir well, wait a short time for the coarser particles to subside, and pour the liquid, holding the undissolved lime in suspension, into a glass-stoppered bottle. Pour off the clear liquid when wanted for use.—U. S.

Wash calcium hydroxide 2 ounces with distilled water until free from chlorides; then shake it with 1 gallon of distilled water contained in a stoppered green-glass bottle for 2 or 3 minutes; set aside for 12 hours. The clear solution may be drawn off with a siphon as it is required for use, or transferred to a green-glass bottle furnished with a well-ground stopper.—Br.

When water is added to burned lime or calcium oxide, this is converted into *calcium hydroxide*, $Ca(OH)_2$, which dissolves in the excess of water. If used for this purpose, the lime should be prepared from marble, when it will be nearly pure; but if made from ordinary limestone, it usually contains alkalies which are readily soluble in water, hence it should be treated with a portion of the water, and this rejected to remove the impurities mentioned. The water should be kept, at a low temperature, upon the lime to retain the solution saturated, and this should be drawn off as needed.

Properties.—Lime water is a clear, colorless, inodorous solution of a slightly alkaline, disagreeable taste, but of a strongly alkaline reaction to test-paper; its specific gravity is 1.0015 at 15° C. (59° F.). When exposed to air, it becomes covered with a pellicle of calcium carbonate; the same compound is formed with loss of the alkaline reaction if carbon dioxide is passed through the solution and the solution heated to expel the excess of the gas (absence of alkalies or alkali carbonates). If lime water is heated to boiling, it becomes turbid from the separation of calcium hydroxide, which dissolves again on cooling. On the addition of test-solution of oxalic acid, lime water yields a white precipitate of calcium oxalate, which is insoluble in acetic, but soluble in hydrochloric, acid.

Tests.—Since at 15° C. (59° F.) lime requires about 780 parts of water for solution, 1 fluidounce (U. S. measure) of lime water contains 0.57 grain of lime or 0.75 grain of calcium hydroxide, which is equal to 0.125 and 0.165 per cent., respectively. At 21° C. (70° F.) 800 parts of water are required for solution, indicating 0.125 per cent. of calcium oxide or 0.166 per cent. of calcium hydroxide. According to Thomas Maben (1883), 1 part of CaO is soluble.

at	10°	20°	30°	40°	60°	80°	99° C.
in	770	791	862	932	1136	1362	1650 parts of water.
equal to	0.129	0.126	0.116	0.107	0.088	0.073	0.06 per cent. CaO.

50 Cc. of lime-water should require, for complete neutralization, not less than 19 Cc. of tenth-normal sulphuric acid (corresponding to about 0.14 per cent. of calcium hydroxide), using phenolphthalein as indicator.—U. S. 24 Cc. should require for neutralization 10 Cc. of tenth-normal solution of sulphuric acid. It should yield no characteristic reaction with the tests for lead or for chlorides.—Br.

Lime-water is a very important article in pharmacy, and should receive careful

attention, as it is chiefly used as an antacid for infants. The supply should be kept in tightly corked bottles, preferably made of green glass, in a cool place, as carbon dioxide is readily absorbed and heat is unfavorable to solution of the lime. Lime water is best decanted from the sediment, or, if filtered, this must be done under cover. It must not be supposed, however, that even the best lime will furnish unlimited quantities of good lime water, and the supply should be tested from time to time, either volumetrically, as directed by the Pharmacopœia, or empirically by breathing into a small quantity of it through a glass tube or boiling a little of it in a test-tube—in either case a turbid liquid should result, due to the separation of calcium carbonate in the first place, or calcium hydroxide in the second.

Action and Uses.—Lime water is an antacid and feeble astringent. It stimulates the flow of the gastric secretion and materially aids in the digestion of milk by preventing too rapid coagulation of the casein. Mixed with an equal quantity of milk and given in small quantities at short intervals, it frequently relieves nausea and vomiting resulting from gastric irritability. It is also useful in the treatment of diarrhœa and diabetes when these conditions are associated with a uric acid diathesis. When given to infants or nursing mothers, it is probably utilized by the organism in the formation of bone.

Externally it is employed as a wash in the treatment of parasitic skin diseases and sluggish ulcerations. Mixed with an equal part of linseed oil, it forms an excellent application for recent burns and scalds. Lime water has also been employed as an injection in the treatment of leucorrhœa and chronic inflammation of the urethra. In the form of a spray it is said to be valuable as a solvent for the false membrane occurring in diphtheria. The dose is from 4 fluidrachms to 4 fluidounces (16–120 Cc.), the smaller amount being preferable for the relief of vomiting.

Allied Preparation.—Liquor Calcis Saccharatus, Br., *Saccharated Solution of Lime.*—Calcium hydroxide, 50 Gm. (or 1 ounce); refined sugar, in powder, 100 Gm. (or 2 ounces); distilled water, 1000 Cc. (or 20 fluidounces). Mix the calcium hydroxide with a solution of the sugar in the distilled water. Set aside in a stoppered green-glass bottle for a few hours, shaking occasionally; separate the clear solution with a syphon, avoiding unnecessary exposure to air.—Br.

It is well known that sugar materially increases the solubility of lime in water, the amount taken up depending upon the temperature and the concentration of the sugar solution. The above preparation contains nearly 2 per cent. of lime (calcium oxide), or about 8 grains in 1 fluidounce. "The specific gravity of saccharated solution of lime is 1.055; 10 Gm. should require for neutralization 6.3 Cc. of volumetric solution of sulphuric acid."—Br.

LIQUOR CALCIS CHLORINATÆ, *Br.*—Solution of Chlorinated Lime.

Chlorure de chaux liquide, Fr.; *Chlorkalklösung*, G.

Preparation.—Take of chlorinated lime, 1 pound; distilled water, 1 gallon. Mix well the water and the chlorinated lime, and, having transferred the mixture to a stoppered bottle, let it be well shaken several times for the space of 3 hours. Pour out now the contents of the bottle on a calico filter, and let the solution which passes through be preserved in a stoppered bottle.—Br.

The solution has the odor, taste, and general properties of chlorinated lime (see page 349). Its specific gravity is about 1.055, and when fresh it should yield about 3 per cent. of available chlorine. The Br. P. requires that the brownish-red solution obtained by adding 1 Cc. of hydrochloric acid to a mixture of 1 Gm. of the solution and 0.5 Gm. of potassium iodide dissolved in water, shall require not less than 5.6 Cc. of decinormal solution of sodium thiosulphate for complete decoloration, which corresponds to 2 per cent. of available chlorine.

Action and Uses.—This solution is employed for the removal of foul odors arising from putrefaction. Applied to the skin it acts as a stimulant, and may be employed as a remedy for chronic cutaneous affections. Internally it is said to be an antidote for hydrocyanic acid. The internal dose is from $\frac{1}{2}$ to 1 fluidrachm (2–4 Cc.), largely diluted with water.

LIQUOR CALUMBÆ CONCENTRATUS, *Br.*—Concentrated Solution of Calumba.

Preparation.—Calumba root, in No. 5 powder, 10 ounces; alcohol (90 per cent.), 4½ fluidounces; distilled water, 20 fluidounces or a sufficient quantity. Macerate the calumba for 24 hours with 10 fluidounces of distilled water; press strongly; again macerate the residue for 24 hours with 10 fluidounces of distilled water; press strongly. Mix the expressed liquids, and heat for 5 minutes to 82.2° C. (180° F.). When cold add the alcohol; set aside; decant or filter, adding sufficient distilled water to produce 1 pint (Imperial measure).—Br.

This is a new preparation in the Br. P., and is in reality a concentrated cold-water infusion, preserved by alcohol, and intended to be used for making infusion of calumba by simple dilution with water. The use of a coarse powder (No. 5, as directed) is necessary to avoid the formation of a thick mucilaginous fluid. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

Action and Uses.—This solution is employed as a bitter tonic. Its uses are mentioned under CALUMBA (which see).

LIQUOR CAOUTCHOUC, *Br.*—Solution of India-rubber.

Preparation.—India-rubber, 1 ounce; benzene and carbon disulphide, of each, 10 fluidounces (Imperial measure). Cut the India-rubber into fine shreds, and place it in a well-stoppered bottle containing the previously mixed benzene and carbon disulphide. Set aside in a cool place, and agitate occasionally until solution is effected.—Br.

This preparation closely resembles the solution of gutta-percha, formerly official in the U. S. P.; the formula is given in the National Formulary, as follows:

LIQUOR GUTTA-PERCHÆ. *Solution of Gutta-percha.*—Gutta-percha, in thin slices, 15 Gm.; commercial chloroform, 100 Cc.; lead carbonate in fine powder, 17 Gm. Add the gutta-percha to 75 Cc. of the chloroform, contained in a bottle, cork it well, and shake it occasionally until the gutta-percha is dissolved. Then add the lead carbonate previously mixed with the remainder of the chloroform, and, having several times shaken the whole together, at intervals of half an hour, set the mixture aside until the insoluble matters have subsided and the solution has become perfectly clear. Lastly decant the liquid and preserve it in small, cork-stoppered vials.—N. F.

The chief use of these solutions is as adhesive agents in the preparation of mustard leaves, although they may also be used in place of collodion as coverings for abraded surfaces. Although the British solution may be more quickly prepared, the disagreeable odor of the carbon disulphide renders it objectionable for many purposes.

Action and Uses.—Solution of gutta-percha is a protective covering to the skin in cases of abrasion or localized superficial inflammation. It is thought by some to be superior to collodion, being non-irritating, more elastic, and less contractile. It may be applied by means of a camel's-hair brush or a glass rod.

LIQUOR CHIRATÆ CONCENTRATUS, *Br.*—Concentrated Solution of Chiretta.

Preparation.—Chiretta, in No. 40 powder, 10 ounces; alcohol (20 per cent.), 25 fluidounces or a sufficient quantity. Moisten the chiretta with 5 fluidounces of the alcohol; pack in a closed percolator; set aside for 3 days; percolate with the remaining alcohol, added in 10 equal portions at intervals of 12 hours; continue percolation with more alcohol until the product measures 1 pint (Imperial measure).—Br.

In the same manner are prepared the following:

LIQUOR CUSPARIÆ CONCENTRATUS, Br.—*Concentrated Solution of Cusparia.*

LIQUOR KRAMERIÆ CONCENTRATUS, Br.—*Concentrated Solution of Krameria.*

LIQUOR SERPENTARIÆ CONCENTRATUS, Br.—*Concentrated Solution of Serpentary.*

These concentrated solutions may be looked upon as weakly alcoholic 50 per cent. tinctures. By some they are considered as concentrated infusions. They are miscible with water and contain sufficient alcohol to preserve them. The dose is from ½ to 1 fluidrachm.

Action and Uses.—The therapeutic value of these preparations is described under the respective drugs from which they are prepared.

LIQUOR CHLORI COMPOSITUS, *U. S.*—Compound Solution of Chlorine.

Soluté de chlore composé, Fr.; *Zusammengesetzte Chlorlösung*, G.

An aqueous solution containing, when freshly prepared, about 0.4 per cent. of chlorine, with some chlorinated products and potassium chloride.—U. S.

Preparation.—Potassium chlorate, granulated, 5 Gm.; hydrochloric acid, 18 Cc.; distilled water, a sufficient quantity to make 1000 Cc. Add the hydrochloric acid, diluted with 20 Cc. of distilled water, to the potassium chlorate contained in a flask of the capacity of about 2000 Cc. Insert in the flask a stopper perforated to admit a funnel of the capacity of about 100 Cc., containing about 10 Gm. of purified cotton, well wetted with cold water; place the flask in a water-bath containing boiling water for a period of from 2 to 3 minutes; when the flask is completely filled with a greenish-yellow gas, remove it from the bath and add cold distilled water through the cotton in the funnel, in four separate portions of 250 Cc. each. After the addition of each separate portion of cold distilled water, stopper the flask securely and thoroughly agitate the contents. This solution should be freshly made when wanted.—U. S.

Although the Pharmacopœia includes the name Chlorine Water among the official titles of this preparation, the latter by no means corresponds to the chlorine water of the 1890 Pharmacopœia, and should not be used when chlorine water is intended as a chemical reagent, since it contains other compounds in solution which might interfere with the reaction desired. Compound solution of chlorine is intended for internal administration of chlorine, and the official formula makes the extemporaneous preparation of the solution an easy task. When moderately dilute hydrochloric acid is allowed to act upon potassium chlorate as directed above, a greenish-yellow gas is formed, which has been called *euchlorine*, and is a mixture of chlorine and chlorine dioxide. The reaction occurring may be shown by the following equation: $2KClO_3 + 4HCl = 2KCl + 2H_2O + 2ClO_2 + Cl_2$. Care is necessary in adding the distilled water, in divided portions, to guard against the loss of chlorine gas when inserting the stopper prior to agitating the flask. The finished solution is a liquid of almost golden-yellow color and a strong chlorine odor. It retains its color for some time, but is best preserved in small bottles, well-stoppered and paraffined.

Physicians will be satisfied to use the above solution in place of chlorine water, as the accompanying impurities are not injurious; but whenever pure chlorine water is desired, the solution mentioned under AQUA CHLORATA (page 215) should be used.

Action and Uses.—As mentioned above, this preparation affords a convenient and efficient substitute for aqua chlorata, to be used as a disinfecting gargle in the putrid sore throat of scarlet fever, diphtheria, smallpox, etc. For this purpose it should be diluted with from 2 to 4 parts of water.

Although better disinfectants are at our disposal, this solution is of value as a local application to suppurating wounds, sloughing ulcers, and gangrene. Its internal administration in typhoid and typhus fever and other diseases is attended with little or no beneficial result; however, in the dose of from ½ to 1 drachm (2–4 Cc.), well diluted, it may correct decomposition in the alimentary canal and correct the fetor of the evacuations.

LIQUOR CRESOLIS COMPOSITUS, *U. S.*—Compound Solution of Cresol.

Liquor cresoli saponatus, P. G.—*Soluté de crésol composé*, Fr.; *Kresolseifenlösung*, G.

Preparation.—Cresol, 500 Gm.; linseed oil, 350 Gm.; potassium hydroxide, 80 Gm.; water, a sufficient quantity to make 1000 Gm. Dissolve the potassium hydroxide in 50 Gm. of water in a tared dish, add the linseed oil, and mix thoroughly. Then add the cresol, and stir until a clear solution is produced, and, finally, sufficient water to make the finished product weigh 1000 Gm.—U. S.

If avoirdupois weight is preferred, 1.6 ounces of potassium hydroxide may be dissolved in 1 ounce of water, 7 ounces of linseed oil added, and finally 10 ounces of

cresol; the weight of the finished product is to be brought up to 20 ounces by addition of water.

The process of solution will be materially expedited if the potassium hydroxide solution be warmed on a bath of hot water during the addition of the linseed oil, in order to effect perfect saponification, and then adding the cresol in divided portions while continuing the heat and stirring constantly.

The directions of the P. G. are almost identical with the above, except that crude cresol is to be used and mixed with an equal weight of soft linseed-oil-potash soap on a water-bath.

Properties.—Compound cresol solution is a clear brownish-yellow liquid, of oil-like consistence, and slippery to the touch. It is apt to become darker with age, and froths considerably when mixed with water and shaken. It has a decided cresol odor, and an alkaline reaction. Prepared with crude cresol, it is of darker, almost brown, color, and has been marketed under such names as *lysol, phenolin, sapocresol,* etc.

Action and Uses.—Compound solution of cresol corresponds in composition to several proprietary preparations which are largely employed as disinfectants and antiseptics in surgical and obstetric practice and household sanitation. Solutions varying in strength of from 1 to 5 per cent. are used as vaginal and intrauterine douches following labor and in acute and chronic inflammations of the pelvic organs; as urethral and vesical irrigations in urethritis and cystitis, as callyrid in gonorrhœal ophthalmia, as general antiseptic applications to wounds, abscesses, ulcers, etc., and to sterilize surgical instruments, the hands of the operator, and the field of operation.

In operations upon the vagina it possesses the advantage over bichloride of mercury solutions in that it renders the parts soft and pliable instead of harsh and rough.

LIQUOR EPISPASTICUS, *Br.*—Blistering Liquid.

Liqueur vésicant, Fr.; *Blasenziehende Flüssigkeit,* G.

Preparation.—Take of cantharides, in powder, 10 ounces; acetic ether, a sufficient quantity. Mix the cantharides with 5 fluidounces of acetic ether; pack in a percolator, and at the expiration of 24 hours pour acetic ether over the contents of the percolator; allow the solution to pass slowly through until 1 pint (Imperial measure) is obtained. —Br.

This preparation is of double the strength of the last (1885) Blistering Liquid. It is chiefly used for making Blistering Collodion. At one time it was known in Great Britain as *Liniment of Cantharides.*

Action and Uses.—Because of the acetic acid present, this solution produces vesication more rapidly than the other preparations of cantharides. It should be thoroughly rubbed into the skin with a brush or mop, and should be applied only over a limited area.

LIQUOR ETHYL NITRITIS, *Br.*—Solution of Ethyl Nitrite.

Solutê de nitrite d'éthyle, Fr.; *Aethylnitritlösung,* G.

Preparation.—Ethyl nitrite made by interaction of 90 per cent. alcohol, sodium nitrite, and diluted sulphuric acid, at a low temperature, is added to a mixture of 95 volumes of absolute alcohol and 5 volumes of glycerin, in the proportion of 3 parts by weight to 97 parts by weight of the glycerin-alcohol mixture.—Br.

Properties and Tests.—Solution of ethyl nitrite is a limpid liquid, practically colorless, of characteristic apple-like odor and taste. It is highly inflammable. Specific gravity 0.823 to 0.826. When solution of ethyl nitrite is poured on an acidulated strong solution of ferrous sulphate contained in a test-tube, a deep olive-brown coloration is produced at the surface of contact of the two liquids, widening as the tube is gently shaken. The solution should not effervesce when shaken carefully with sodium bicarbonate (absence of acid). 10 Cc. of the solution mixed with 5 Cc. of volumetric solution of sodium hydroxide and 5 Cc. of water should not assume a yellow color (absence of aldehyde). 1 volume of solution, agitated briskly at intervals during 5 minutes in a brine-charged nitrometer with 1 volume of solution of potassium iodide and 1 volume of diluted sulphuric acid, should yield, at the ordinary temperature, 15.5° C. (60° F.), and pressure, and when freshly prepared, at least 7.6 volumes of nitric oxide gas; and even after the solution of ethyl nitrite has been kept for some time, and the vessel con-

taining it has occasionally been opened, it should possess at least five-sixths of the strength just indicated.—Br.

Solution of ethyl nitrite was introduced into the last edition of the British Pharmacopœia evidently for the purpose of providing a more stable preparation than the well-known spirit of nitrous ether, from which latter it differs but slightly in strength. It is well known that the presence of water predisposes ethyl nitrite to decomposition, and hence the spirit of that name has often been found unsatisfactory. By dissolving freshly made ethyl nitrite in absolute alcohol the tendency to deteriorate is very materially lessened. Owing to its low boiling-point, solution of ethyl nitrite should be preserved in small vials in a cool place.

Action and Uses.—This solution may be employed for the same conditions and in the same doses as SPIRITUS ÆTHERIS NITROSI (which see).

LIQUOR FERRI ACETATIS, *Br.*—Solution of Ferric Acetate.

Acétate ferrique liquide, Fr.; *Ferriacetatlösung*, G.

Preparation.—Solution of ferric sulphate, 2½ fluidounces; solution of ammonia, 4 fluidounces; glacial acetic acid, liquefied, 1½ fluidounces; distilled water, a sufficient quantity. Mix the solution of ammonia with 1 pint (Imperial measure) of distilled water; gradually add to this the solution of ferric sulphate diluted with 1 pint (Imperial measure) of distilled water; stir well together, taking care that ammonia is, even finally, in slight excess, as indicated by the odor of the mixture; let the whole stand for 2 hours, stirring occasionally; transfer to a calico filter; wash the precipitated ferric hydroxide with distilled water until free from sulphates; let drain; squeeze it to remove superfluous moisture; dissolve it in the glacial acetic acid; make the volume up to 1 pint (Imperial measure) with distilled water; allow any insoluble matter to subside; pour off the clear solution.—Br.

Properties.—Solution of ferric acetate, made as above, is a red liquid, having the specific gravity 1.031, and is miscible in all proportions with water and 90 per cent. alcohol. It has an acetous odor and a sour, styptic taste. The Br. P. demands the absence of lead, copper, arsenic, zinc, calcium, sodium, ammonium, potassium, ferrous salts, and nitrates, and permits only very slight reactions with the tests for sulphates.

Solution of ferric acetate has been dropped from the U. S. and German pharmacopœias. The former (1890) gave the following directions for preparing a solution of about 1.160 specific gravity, which is very much stronger than the above, containing about 33 per cent. of anhydrous ferric acetate, $Fe_2(C_2H_3O_2)_6$, and representing about 7.5 per cent. of metallic iron. Solution of ferric sulphate, 1000 Gm.; glacial acetic acid, 260 Gm.; ammonia water, 850 Cc.; water, distilled water, each a sufficient quantity to make 1000 Gm. Mix the ammonia water with 3000 Cc. of cold water, and the solution of ferric sulphate with 10,000 Cc. of cold water. Add the latter solution slowly to the diluted ammonia water, stirring constantly. Let the mixture stand until the precipitate has subsided as far as practicable, and then decant the supernatant liquid. Add to the precipitate 6000 Cc. of boiling water, mix well, and set the mixture aside, as before. Repeat the washing with successive portions of boiling water, in the same manner, until the washings are no longer affected by sodium cobaltic nitrite test-solution (showing the removal of ammonia and its salts). Transfer the mixture to a wet muslin strainer, allow the precipitate to drain completely, and press it, folded in the strainer, until its weight is reduced to 700 Gm. or less. Now add the precipitate gradually to the glacial acetic acid contained in a jar provided with a glass stopper, stirring the mixture after each addition until each portion added is nearly dissolved before adding another portion. Finally, add sufficient distilled water to make the product weigh 1000 Gm.; mix thoroughly; allow it to become clear by subsidence, and decant the clear solution. Keep the product in well-stoppered bottles, in a cool place, protected from light.

To make 1 pint of this solution 14 fluidounces of solution of ferric sulphate should be diluted with 10 pints of water, and then poured slowly into a mixture of 15¼ fluidounces of ammonia water and 4 pints of water. The well-washed and drained precipitate, free from ammonium salts, should be dissolved in 4 fluidounces of glacial acetic acid, as directed above, and finally sufficient distilled water added to bring the volume of finished product up to 16 fluidounces.

Action and Uses.—This solution combines the properties of a chalybeate and astringent. It may be employed for the same purposes as the other astringent preparations of iron, but for internal use is probably of less value than the tincture of ferric acetate. The dose is from 5 to 10 minims (0.3–0.6 Cc.).

LIQUOR FERRI CHLORIDI, *U. S.*—Solution of Ferric Chloride.

Liquor ferri perchloridi fortis, Br.; *Liquor ferri sesquichlorati*, P. G.; *Liquor ferri muriatici oxydati.—Solution of chloride of iron, Strong solution of ferric chloride*, E.; *Solution de perchlorure de fer, Chlorure ferrique liquide*, Fr.; *Eisenchloridlösung, Flüssiges Eisenchlorid*, G.

The specific gravities of the official solutions of ferric chloride are—1.315 U. S., 1.42 Br., 1.280 to 1.282 P. G., and they contain not less than 29 per cent. U. S. (with some free hydrochloric acid), about 46 per cent. Br., 29.02 per cent. P. G., of anhydrous ferric chloride, representing, respectively, 10, 15.84, and 10 per cent. of metallic iron.

Preparation.—Iron, in the form of fine wire and cut into small pieces, 125 Gm.; hydrochloric acid, 680 Gm.; nitric acid, distilled water, each a sufficient quantity to make 1000 Gm. Put the iron wire into a flask capable of holding double the volume of the intended product. Pour upon it 420 Gm. of hydrochloric acid previously diluted with 250 Cc. of distilled water, and heat upon a water-bath for not less than 1 hour and 15 minutes or until effervescence ceases; then boil the liquid, filter it through paper, and, having rinsed the flask and iron wire with a little boiling distilled water, pass the washings through the filter. To the filtered liquid add 220 Gm. of hydrochloric acid, and pour the mixture, slowly and gradually, in a stream, into 65 Gm. of nitric acid contained in a capacious porcelain vessel, and warm gently. After effervescence ceases apply heat, by means of a sand-bath, until the liquid is free from nitric acid. If the solution has acquired a black color, continue the addition of nitric acid, drop by drop, until red fumes are no longer evolved, and the solution assumes a clear reddish-brown color. Finally, add the remaining 40 Gm. of hydrochloric acid, and sufficient distilled water to make the whole weigh 1000 Gm.—U. S.

To prepare 1 pint of solution of ferric chloride would require 1550 grains of iron wire, 105 fluidrachms of hydrochloric acid (divided into three portions of 64, 34, and 7 fluidrachms, respectively), and $6\frac{1}{2}$ fluidrachms of nitric acid. The first portion of hydrochloric acid should be diluted with 6 fluidounces of distilled water.

Liquor Ferri Perchloridi Fortis, Br.—Mix iron wire, 4 ounces; hydrochloric acid, $12\frac{1}{2}$ fluidounces; and water, 7 fluidounces; when effervescence ceases, heat to boiling, filter, rinse the flask and contents with a little water, and pour this over the filter; add to the filtrate hydrochloric acid, 7 fluidounces; then pour the solution in a slow continuous stream into $1\frac{1}{2}$ fluidounces of nitric acid, the evolution of red fumes being promoted, if necessary, by a slight application of heat. Evaporate the product until no more nitrous fumes escape and a precipitate begins to form; then add hydrochloric acid 1 fluidounce and sufficient water to produce $17\frac{1}{2}$ fluidounces of the solution.—Br.

Liquor Ferri Perchloridi, Br.—Mix strong solution of ferric chloride 1 fluidounce with distilled water sufficient for 4 fluidounces. Its specific gravity is 1.11.

The reactions which take place in the preparation of solution of ferric chloride result first in the formation of ferrous chloride, and subsequently in the conversion of this salt into ferric chloride with escape of nitric oxide, as shown by the following equations: $Fe + 2HCl = FeCl_2 + H_2$; $6FeCl_2 + 2HNO_3 + 6HCl = 6FeCl_3 + 2NO + 4H_2O$. The U. S. P. solution contains about 1.6 per cent. of uncombined HCl.

Properties.—Solution of ferric chloride is a reddish-brown liquid, which has a faint odor of hydrochloric acid, an acid reaction, and a strongly styptic taste. It may be mixed with water and alcohol in all proportions without producing a precipitate. Diluted with water, it gives a brown precipitate with ammonia or potassium hydroxide, a white one with silver nitrate (chloride), and a dark-blue precipitate of Prussian Blue with potassium ferrocyanide. It is not altered by exposure to the sunlight, except in the presence of various organic matters, by which the salt is partly reduced to ferrous chloride; and it remains clear when heated to boiling unless ferric oxychloride be present, when it becomes turbid, a slight turbidity being best observed in reflected light. On being evaporated

to dryness a reddish-brown salt is left, which at a red heat is partly decomposed and partly volatilized.

Tests.—The same reactions which are used for determining the purity of the salt (see FERRI CHLORIDUM, page 620) are likewise employed for this solution. On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the solution (1 in 10), the crystal should not become colored brown, nor should a brownish-black color develop around it (absence of nitric acid). A freshly prepared solution of potassium ferricyanide should color the solution olive-brown, but not blue (ferrous salt). If the iron be completely precipitated from a portion of the solution by an excess of ammonia water, the filtrate should be colorless, and should not yield a precipitate with hydrogen sulphide test-solution (absence of zinc or copper); nor should it leave a fixed residue on evaporation and gentle ignition (absence of salts of the fixed alkalies). If to 3 drops of solution of ferric chloride 10 Cc. of tenth-normal sodium thiosulphate test-solution be added, and then slowly heated to boiling, no brown precipitate of ferric hydroxide should separate (absence of oxychloride). If 10 Gm. of the solution be diluted to measure 100 Cc., and 11.1 Cc. be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 10 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be allowed to stand for half an hour at a temperature of 40° C. (104° F.), then cooled and mixed with a few drops of starch test-solution, it should require not less than 20 Cc. of tenth-normal sodium thiosulphate solution to discharge the blue or greenish color of the liquid (each Cc. of the volumetric solution consumed corresponding to 0.5 per cent. of metallic iron).—U. S. 5 Cc. of the solution, diluted with 80 Cc. of water, and mixed with an excess of ammonia water, should yield a reddish-brown precipitate which, when washed and incinerated, weighs 1.6 Gm.—Br.

Action and Uses.—Because of its astringent properties this solution is employed as a hæmostatic agent. It causes immediate coagulation of the blood when injected into veins or applied to an open wound. For this reason it has been employed as an injection for the cure of varices, hemorrhoids, and aneurisms. It has been injected into fatty tumors with the object of effecting their removal, but the procedure is attended with danger. Diluted with water and locally applied, it is sometimes useful in reducing the size of nasal polypi and erectile tumors. When sufficiently diluted (1 : 32), it may be employed in the treatment of post-partum hemorrhage. Internally it is usually employed in the form of TINCTURA FERRI CHLORIDI (which see). The dose of the solution is from 2 to 10 minims (0.10–0.6 Cc.), largely diluted and taken through a glass tube.

Allied Preparations.—FERRUM DIALYSATUM. *Liquor ferri dialysatus; Liquor ferri oxychlorati*, P. G.; *Dialyzed iron, Solution of oxychloride of iron*, E.; *Fer dialysé*, Fr.; *Eisenoxychloridlösung, Flüssiges Eisenoxychlorid*, G.

Dialyzed iron is made by saturating an aqueous solution of ferric chloride with ferric hydroxide, putting the liquid into a dialyzer, and suspending this in water which is often renewed—as long, indeed, as it acquires an acid reaction. Very little iron will pass through the parchment septum; when dialysis is completed, the ferric solution is diluted, so that 100 grains of it, when evaporated and dried at a temperature not exceeding 100° C. (212° F.), will leave a solid residue weighing 5 grains.

Similar solutions were obtained by Ordway (1858) and Béchamp (1859) by leaving pure ferric hydroxide in contact with ferric chloride for a prolonged time. Th. Graham (1861) subjected this to dialysis, and succeeded in removing the acid until chlorine corresponding to 1.5 per cent. of HCl was left. Such a solution, however, which would correspond to $Fe_2Cl_6.95Fe_2O_3$, gelatinized ultimately.

E. Scheffer (1878) showed that by precipitation with ammonia very basic oxychlorides of iron may be obtained, which, after having been thoroughly washed, will slowly dissolve in distilled water. The limits at which a soluble precipitate is obtained appear to have been reached on mixing 150 volumes of the official solution of ferric chloride with 91.5 volumes of ammonia water. The washed precipitate contained 97.83 per cent. Fe_2O_3 to 2.17 per cent. Fe_2Cl_6, and required over 7 weeks for effecting solution in distilled water.

The German Pharmacopœia does not direct dialysis, but has adopted the following process: Dilute solution of ferric chloride (specific gravity 1.281) 35 parts with water 160 parts, and pour the mixture slowly into ammonia water 35 parts, previously diluted with water 320 parts; wash the precipitate, express, and add hydrochloric acid (specific gravity 1.124) 3 parts; agitate occasionally for 3 days, then warm gently until solution has been effected, and dilute with water until the liquid has the specific gravity 1.050.

Owing to the retention of ammonia by ferric hydroxide, solutions of the latter in acid

or ferric chloride must vary somewhat in character, and therefore are properly subjected to dialysis for separating ammonium chloride and increasing the basic character of the ferric oxychloride.

Liquid oxychloride or dialyzed iron is perfectly transparent in thin layers of a deep brown-red color, inodorous, and almost destitute of styptic taste. It is miscible with alcohol, glycerin, syrup, and distilled water, but not with spring water or other, even dilute, saline solutions. A small quantity of tannin merely darkens the liquid; a larger quantity causes a deep-brown gelatinous precipitate. A minute quantity of silver nitrate will not disturb the liquid; a larger quantity will cause a gelatinous brown precipitate, which is again soluble in distilled water; but on adding first a slight excess of ammonia, filtering from the ferric hydroxide, acidulating with nitric acid, and then testing with silver nitrate, a white precipitate of silver chloride is formed. If to 1 Cc. of the liquid, diluted with 19 Cc. of distilled water, 1 drop each of nitric acid and 5 per cent. silver nitrate solution be added, the mixture should be clear in transmitted light.—P. G. This test indicates the thorough washing of the ferric hydroxide and the absence of ammonium chloride from the solution; a few drops more of either the acid or test-solution will cause a turbidity or precipitate. Prepared by the P. G. process, it has the specific gravity 1.050, and contains nearly 3.5 per cent. of iron or about 7 per cent. of oxychloride, having approximately the composition $Fe_2Cl_6.8Fe_2(OH)_6$. A solution which, when evaporated on a water-bath until the residue is pulverulent and weighs 5 per cent., has, according to E. B. Shuttleworth (1877), the specific gravity 1.034. If 5 per cent. of residue is left after completely drying on a water-bath, the specific gravity is 1.040, and if the same amount of residue is left after ignition, the specific gravity of the solution is 1.046.

Liquor Ferri Albuminati, P. G. *Solution of iron albuminate*, E.; *Eisenalbuminatlösung*, G.—This is prepared as follows: 35 parts of dry egg-albumen are dissolved in 1000 parts of water, the solution strained and poured slowly and in a thin stream, under constant stirring, into a mixture of 120 parts of oxychloride of iron solution and 1000 parts of water; the precipitate is well washed with water until all chlorine is removed, and then dissolved in a mixture of 3 parts of 15 per cent. sodium hydroxide solution and 50 parts of water. To the solution are added 150 parts of alcohol, 100 parts of cinnamon water, 2 parts of aromatic tincture, and sufficient water to make the finished product weigh 1000 parts. It contains about 0.4 per cent. of metallic iron and mixes clear with alcohol. (See Ferri Albuminas.)

Liquor Ferri Peptonati. *Solution of iron peptonate*, E.; *Eisenpeptonatessenz*, G.—The supplement of the 1890 P. G. directs the preparation as follows: Dry peptone, 8 Gm., are dissolved in 100 Gm. of hot water, and to the solution, when cold, are added 174 Gm. of solution of oxychloride of iron (specific gravity 1.050), gradually and with constant stirring. The fluid is exactly neutralized by means of dilute sodium hydroxide solution and the resulting precipitate washed by decantation with distilled water until the washings are no longer affected by silver nitrate solution. The precipitate is drained on a muslin strainer, mixed with 200 Gm. of simple syrup, warmed, and dissolved by the careful addition of dilute (1.5 per cent.) sodium hydroxide solution. To this solution are finally added alcohol, 100 Gm.; tincture of orange peel, 3 Gm.; aromatic tincture and tincture of vanilla, of each 1.5 Gm.; acetic ether, 5 drops, and sufficient distilled water to make the total product weigh 1000 Gm. It is a clear reddish-brown liquid, containing about 0.6 per cent. of metallic iron, and should be protected against light. (See Ferri Peptonas.)

These so-called *indifferent iron preparations* are very sensitive to carbon dioxide and sodium chloride, and hence they must be prepared as rapidly as possible and with distilled water previously boiled and cooled again.

LIQUOR FERRI ET AMMONII ACETATIS, *U. S.*—Solution of Iron and Ammonium Acetate.

Mistura ferri et ammonii acetatis, U. S. P., 1880.—*Basham's Mixture.*

Preparation.—Tincture of ferric chloride, 40 Cc.; diluted acetic acid, 60 Cc.; solution of ammonium acetate, 500 Cc.; aromatic elixir, 120 Cc.; glycerin, 120 Cc.; water, a sufficient quantity to make 1000 Cc. To the solution of ammonium acetate (which should not be alkaline) add, successively, the diluted acetic acid, the tincture of ferric chloride, the aromatic elixir, and the glycerin, and lastly, sufficient water to make the product measure 1000 Cc. This preparation should be freshly made when wanted. —U. S.

To prepare 1 pint of Basham's Mixture would require 308 minims of tincture of ferric chloride, 460 minims of diluted acetic acid, 8 fluidounces of solution of ammonium acetate, 2 fluidounces of aromatic elixir, 2 fluidounces of glycerin, and sufficient water to bring the volume up to 16 fluidounces.

Basham's Mixture, as prepared by the present official formula, is about twice as strong as that of the 1890 Pharmacopœia.

This preparation was at one time the cause of much annoyance to the pharmacist on account of its instability. As now made, it keeps perfectly; although the Pharmacopœia directs that it shall be freshly made when wanted, this is scarcely necessary; we have found it to remain unchanged for a period of 75 days, exposed to diffused light at summer temperature. The use of glycerin in place of simple syrup was first suggested by H. R. LeValley (*Drugg. Circ.*, 1887).

Ferric chloride and ammonium acetate mutually decompose each other, forming ferric acetatic and ammonium chloride, some of the ammonium acetate remaining unchanged. The deep-red color of the liquid is due to the newly formed ferric acetate.

Action and Uses.—This astringent chalybeate is largely employed in the treatment of chronic nephritis. It produces diuresis, decreases albuminuria, and is considered the best preparation of iron to employ for combating the anæmia of Bright's disease. The dose is from 2 to 8 fluidrachms (8–30 Cc.).

LIQUOR FERRI PERNITRATIS, *Br.*—Solution of Ferric Nitrate.

Solution of nitrate of iron, E.; *Azotate de fer liquide*, Fr.; *Eisennitratlösung, Ferrinitratlösung*, G.

Preparation.—Iron, 1 ounce; nitric acid, 4½ fluidounces; distilled water, a sufficient quantity. Dilute the nitric acid with 16 ounces of the distilled water; introduce the iron; set aside until the metal is dissolved, taking care to moderate the action, should it become too violent, by the addition of a little more distilled water; filter the liquid; add sufficient distilled water to produce 30 fluidounces (Imperial measure).—Br.

Properties.—Solution of ferric nitrate is a clear, reddish-brown liquid, of 1.107 specific gravity, and having a distinctly acid and astringent taste. It remains unaltered on exposure to light and air except in the presence of organic compounds, by many of which it is deoxidized. It affords the reactions characteristic of ferric salts and of nitrates.

Tests.—Potassium ferricyanide, silver nitrate, and barium nitrate should not disturb the solution, proving the absence of ferrous salt, chloride, and sulphate. If precipitated with an excess of ammonia, the filtrate evaporated to dryness, and the salt heated to redness, no residue should be left (showing the absence of other metals). The Br. P. requires that 5 Cc. treated with an excess of solution of ammonia shall give a precipitate which, when washed, dried, and incinerated, weighs 0.23 Gm. Such a residue would correspond to the presence of about 12.6 per cent. of anhydrous ferric nitrate, representing 2.98 per cent. of metallic iron.

The U. S. P. no longer recognizes this preparation. That of 1890 directed it to be made by dissolving the well-washed and drained ferric hydroxide, obtained from 180 Gm. of solution of ferric sulphate by means of diluted ammonia water, in nitric acid 71 Gm., and finally adding sufficient distilled water to make the finished product weigh 1000 Gm. This solution was weaker than the above, having a specific gravity of 1.050 and containing only 6.2 per cent. of anhydrous ferric nitrate.

Following the directions of the Br. P., ferric nitrate is formed with the evolution of red vapors, according to the equation $Fe_2 + 8HNO_3 = 4Fe_2(NO_3)_6 + 2NO + 4H_2O$. Considerable heat is produced, and the reaction must be closely watched, and moderated if necessary by the addition of cold water. If the acid is somewhat in excess in the finished product, the color will be much lighter, and a colorless solution may even result. Ferric nitrate has been obtained in deliquescent colorless crystals containing 12 or 18 molecules of water, and yielding colored solutions.

Action and Uses.—This solution is more astringent than the vegetable salts of iron, and less so than those prepared with sulphuric or hydrochloric acid. It may be employed in the treatment of chronic diarrhœa, dysentery, mucous diarrhœa, and in leucorrhœa and menorrhagia occurring in feeble and anæmic individuals. In the latter conditions it is employed internally and also in the form of an injection containing from 10 to 30 minims (0.6–2.0 Cc.) to 1 ounce (30 Cc.) of water. The internal dose is from 5 to 10 minims (0.3–0.6 Cc.), well diluted.

LIQUOR FERRI SUBSULPHATIS, *U. S.*—Solution of Ferric Subsulphate.

Solution of basic ferric sulphate, Solution of persulphate of iron, Monsel's Solution, E.; *Liqueur hémostatique de Monsel,* Fr.; *Basisch-schwefelsaure Eisenoxydlösung, Monselsche Eisenlösung,* G.

An aqueous solution of basic ferric sulphate (of variable chemical composition), representing not less than 13.57 per cent. of metallic iron.

Preparation.—Ferrous sulphate, in clear crystals, 675 Gm.; sulphuric acid, 65 Gm.; nitric acid, distilled water, each a sufficient quantity to make 1000 Gm. Add the sulphuric acid to 500 Cc. of water in a capacious porcelain dish, heat the mixture to nearly 100° C. (212° F.), and then add 70 Gm. of nitric acid, and mix well. Divide the coarsely powdered ferrous sulphate into four equal portions, and add one of these portions, at a time, to the hot liquid, stirring after each addition, until effervescence ceases. When all the ferrous sulphate has been dissolved, add a few drops of nitric acid, and if this causes a further evolution of red fumes, continue to add nitric acid, a few drops at a time, until it no longer causes red fumes to be evolved; then boil the solution until it assumes a ruby-red color and is free from nitrous odor. Lastly, add sufficient distilled water to make the product weigh 1000 Gm. Keep the product in well-stoppered bottles, in a moderately warm place (not under 22° C. or 71.6° F.), protected from the light.—U. S.

Note.—Solution of subsulphate of iron is to be dispensed when solution of persulphate of iron is prescribed by the physician.

To prepare 1 pint of Monsel's Solution would require 1 pound and 650 grains of ferrous sulphate, 736 grains each of sulphuric and nitric acids, and a sufficient quantity of distilled water, 12 fluidounces being used to dilute the acids in the first instance.

This process is a slight modification of that proposed by Dr. Squibb (1860). On introducing the ferrous sulphate in small portions into the heated acids, a black color is produced from the union of nitric oxide with ferrous sulphate, which disappears with the copious evolution of red nitrous vapors as fast as the sulphate dissolves in the hot liquid. The mixture foams most toward the end of the process, and after the liquid has again subsided, a little of it should be tested with nitric acid to insure its complete oxidation. The amount of sulphuric acid used is insufficient for forming the normal ferric sulphate. A basic or oxysulphate is the result, which has the composition $Fe_4O(SO_4)_5 + Aq$, or $5Fe(SO_4)_3.Fe(OH)$. The mineral *copiapite* is a crystallized hydrate of the same combination. Other more basic ferric sulphates are known, some being soluble, others insoluble, in water.

Properties.—Monsel's Solution is a deep red-brown liquid, being nearly of a syrupy consistence, and of specific gravity 1.548 at 25° C. (77° F.). It is almost inodorous, has a very astringent but not caustic taste, and an acid reaction, and mixes with water and alcohol in all proportions without decomposition. On dropping sulphuric acid into it the color becomes lighter, and with a larger quantity (½ volume) of the acid a separation of whitish anhydrous ferric sulphate takes place (difference from solution of tersulphate). Diluted with distilled water, it yields a red-brown precipitate with ammonia or potassa, a dark-blue one with potassium ferrocyanide, and a white one insoluble in nitric or hydrochloric acid with barium chloride. When evaporated at a moderate heat upon a glass or porcelain plate, it yields transparent, deliquescent scales, and at a somewhat higher temperature is converted into a yellowish powder which is less deliquescent.

Tests.—The solution, diluted with 20 parts of water, should be colored a pure brown with freshly prepared solution of potassium ferricyanide, and it should not at once turn green or greenish blue (absence of ferrous salt). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the solution, the crystal should not become brown, nor should there be a brownish-black zone developed around it (absence of nitric acid). If 10 Gm. of the solution be diluted to measure 100 Cc., and 11.1 Cc. of this liquid be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 10 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be allowed to stand for half an hour at a temperature of 40° C. (104° F.), and then cooled, and mixed with a few drops of starch test-solution, it should require not less than 27.2 Cc. of tenth-normal sodium thiosulphate solution to discharge the blue or

greenish color of the liquid (each Cc. of the volumetric solution consumed corresponding to 0.5 per cent. of metallic iron).—U. S.

Action and Uses.—Monsel's Solution is a very powerful styptic, and because of its deficiency in sulphuric acid, is less irritating than ferric sulphate. This renders it useful in the control of hemorrhage from incised wounds, the nasal cavities, etc., in which it is desirable to produce as little irritation as possible. Diluted with water, it has been used in the form of a spray in the treatment of epistaxis and hæmoptysis. It may be locally applied to bleeding cavities after the extraction of teeth, and when given internally is said to control hemorrhage from the stomach. The internal dose is from 5 to 10 minims (0.3–0.6 Cc.), largely diluted with water. When used in the atomizer, the solution should contain 10 minims (0.6 Cc.) to 1 ounce (30 Cc.) of water.

LIQUOR FERRI TERSULPHATIS, *U. S.*—Solution of Ferric Sulphate.

Liquor ferri persulphatis, Br.; *Solution of normal ferric sulphate*, E.; *Persulfate de fer liquide*, Fr.; *Ferrisulfatlösung, Schwefelsaure Eisenoxydlösung*, G.

An aqueous solution of normal ferric sulphate, $Fe_2(SO_4)_3$, containing about 36 per cent. of the salt, and representing not less than 10 per cent. of metallic iron.

Preparation.—Ferrous sulphate, in clear crystals, 500 Gm.; sulphuric acid, 96 Gm.; nitric acid, distilled water, each a sufficient quantity to make 1000 Gm. Add the sulphuric acid to 250 Cc. of water in a capacious porcelain dish, heat the mixture to nearly 100° Cc. (212° F.), then add 56 Gm. of nitric acid, and mix well. Divide the coarsely powdered ferrous sulphate into four equal portions, and add these portions, one at a time, to the hot liquid, stirring after each addition until effervescence ceases. When all the ferrous sulphate has been dissolved, if the solution has acquired a black color, add nitric acid, a few drops at a time, heating and stirring until it no longer causes red fumes to be evolved, and the solution assumes a clear reddish-brown color; then boil the liquid until it is free from nitric acid. Lastly, add sufficient distilled water to make the product weigh 1000 Gm. Filter if necessary.—U. S.

To prepare 1 pint of solution of ferric sulphate would require 11 avoirdupois ounces of ferrous sulphate, 940 grains of sulphuric acid, 540 grains of nitric acid, and a sufficient quantity of distilled water, of which 4½ fluidounces should be used for dilution of the acids.

Take of ferrous sulphate, 8 ounces; sulphuric acid, nitric acid, of each, 6 fluidrachms; distilled water, a sufficient quantity. Add the sulphuric acid to 10 ounces of the water, and dissolve the ferrous sulphate in the mixture with the aid of heat. Mix the nitric acid with 2 ounces of the water, and add to this acid, warmed, the solution of ferrous sulphate. Concentrate the whole by boiling until, by the sudden disengagement of ruddy vapors, the liquid ceases to be black and acquires a red color. If any ferrous salt remains in the solution, add a few drops of nitric acid, and boil again. When the solution is cold, make the quantity 11 fluidounces (Imperial measure) by the addition, if necessary, of distilled water.—Br.

The reaction which takes place in these processes is precisely the same as in making the subsulphate of iron, the only difference being that the sulphuric acid is used in sufficient quantity to form normal ferric sulphate, $Fe_2(SO_4)_3$. The reaction is explained by the equation $6FeSO_4 + 3H_2SO_4 + 2HNO_3 = 3Fe_2(SO_4)_3 + N_2O_2 + 4H_2O$. From 100 parts of ferrous sulphate, 200 parts, U. S. (198.14 parts, Br.) of the solution are prepared.

Properties.—Solution of normal ferric sulphate is a dark, reddish-brown liquid, having no odor, a very astringent and at the same time acid taste, and an acid reaction. It is miscible in all proportions with alcohol and water without causing decomposition. Its behavior to ammonia, potassium ferrocyanide, and barium chloride is the same as that of the subsulphate, but for the precipitation of the anhydrous salt about 3 volumes (instead of ½ volume) of sulphuric acid are required. On slowly mixing 2 volumes of the solution with 1 volume of concentrated sulphuric acid, in a beaker, no solid white mass will separate on standing (difference from subsulphate). The pharmacopœial solution contains 36 per cent. U. S., 36.3 per cent. Br., of anhydrous ferric sulphate, and has the specific gravity 1.432 at 25° C. (77° F.) U. S., 1.441 at 15.5° C. (60° F.) Br. Hager gives the following densities for solutions containing the anhydrous salt—

25	26	27	28	28.5	29	29.5	30	31	32 per cent.
1.271	1.284	1.297	1.310	1.316	1.323	1.330	1.337	1.351	1.365

Tests.—The absence of ferrous salt, chloride, nitric acid, and foreign salts is determined in precisely the same manner as for the subsulphate (which see). If 1.11 (1.1176) Gm. of the solution be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be allowed to stand for half an hour at a temperature of 40° C. (104° F.), then allowed to cool, and mixed with a few drops of starch test-solution, it should require not less than 20 Cc. of tenth-normal sodium thiosulphate solution to discharge the blue or greenish color of the liquid (each Cc. of the volumetric solution consumed corresponding to 0.5 per cent. of metallic iron).—U. S. 5 Cc. of the solution diluted with 80 Cc. of water and mixed with an excess of ammonia water should yield a precipitate which, when washed and ignited, weighs 1.04 Gm.—Br.

Action and Uses.—This preparation may be substituted for Liquor Ferri Subsulphatis. It should be remembered, however, that the latter is less irritating and more astringent. The principal employment of the tersulphate is in the preparation of the arsenic antidote.

LIQUOR FORMALDEHYDI, *U. S.*—Solution of Formaldehyde.

Formaldehydum solutum, P. G.—*Formol, Formalin*, E., G.; *Soluté d'aldéhyde formique*, Fr.; *Formaldehydlösung*, G.

An aqueous solution containing not less than 37 per cent., by weight, of absolute formaldehyde (CH_2O or HCHO = 29.79), a product of the partial oxidation of methyl alcohol. It should be kept in well-stoppered bottles, in a cool place, protected from light.—U. S.

Preparation.—Formaldehyde solution is prepared by passing heated vapors of methyl alcohol mixed with air over heated copper spirals, or coke, or by passing methane (marsh gas) over a heated mixture of copper, pumice, and asbestos fibres, and then passing the products of the resulting oxidation into water and removing undecomposed methyl alcohol by subsequent distillation. The solution thus obtained is finally adjusted to the proper strength either by dilution or by concentration.

Properties.—The official solution is a clear, colorless liquid, having a specific gravity of 1.075–1.078 at 25° C. (77° F.), a pungent odor, a caustic taste, and an irritating action upon mucous surfaces. It is miscible with water and alcohol in all proportions, but is not miscible with ether. On standing, the solution sometimes becomes milky in appearance, due to the separation of paraformaldehyde. The aqueous solution shows a neutral reaction with litmus, but owing to slow oxidation of the formaldehyde by the air, resulting in the formation of formic acid, its reaction is frequently slightly acid. If 1 volume of the solution be mixed with 5 volumes of distilled water and then treated with an ammoniacal solution of silver nitrate, a gray precipitate of metallic silver, in finely divided form, will be produced, which often adheres as a metallic mirror to the sides of the test-tube. Formaldehyde solution added to an alkaline cupric tartrate solution and then heated, causes the separation of red cuprous oxide, the liquid becoming colorless. If the aqueous solution of formaldehyde be evaporated over sulphuric acid, or in a vacuum, white solid paraformaldehyde is rapidly formed, which is insoluble in water, and which sublimes at about 100° C. (212° F.) and melts at 153°–172° C. (307.4°–341.6° F.), and is resolved into ordinary gaseous formaldehyde. The same result is obtained if the solution be evaporated to dryness on a water-bath; but if the solution, previous to evaporation, be made alkaline by addition of ammonia water, a white crystalline residue is obtained, known as hexamethylenetetramine, which is readily soluble in water.

Tests.—If 5 Cc. of sulphuric acid (specific gravity 1.34) be placed in a test-tube and a little salicylic acid be dissolved in it, and 2 drops of formaldehyde solution be added and the liquid be very gently warmed, a permanent deep-red color should immediately appear. If 20 Cc. of the solution be evaporated to dryness on a water-bath, a white amorphous mass should remain, which upon ignition should not leave a residue (absence of mineral matter). If 20 Cc. of formaldehyde solution, to which a couple of drops of phenolphthalein test-solution have been added, be titrated with normal potassium hydroxide solution, not more than 0.5 Cc. of the normal solution should be required for neutralization (absence of more than 0.1 per cent. of formic and other acids). If 20 Cc. of the solution be diluted with 60 Cc. of distilled water and the liquid be divided

into approximately four equal portions, no turbidity or precipitate should be produced on the addition to one portion of silver nitrate test-solution (absence of chloride); barium chloride test-solution to the second portion (absence of sulphate); hydrogen sulphide or potassium ferrocyanide test-solution to the third portion (absence of metals); ammonium oxalate test-solution to the fourth portion (absence of calcium).—U. S. If 100 Cc. of formaldehyde solution be treated with 100 Cc. of ammonia water, and allowed to stand at least 6 hours and then distilled until 25 Cc. of distillate have been collected, and to the distillate thus obtained, a quantity of salicylic acid about the size of a pea, and sulphuric acid equal to about one-third the volume of the distillate be added, and the whole heated for a few minutes, no odor of oil of wintergreen should be observed in the cooled liquid (absence of methyl alcohol). If 10 Cc. of the solution be mixed with 10 Cc. of iodine test-solution, and potassium hydroxide test-solution be added drop by drop until the yellow color of the liquid disappears, no milky turbidity should be produced, nor should the odor of iodoform be developed (absence of acetone).

Assay of Formaldehyde Solution.—The U. S. P. prescribes the following method for determining the percentage of formaldehyde present: Transfer 3 Cc. of solution of formaldehyde to a well-stoppered Erlenmeyer flask, and weigh accurately. Add 50 Cc. of normal solution of sodium hydroxide, and follow this immediately, but slowly, through a small funnel, with 50 Cc. of solution of hydrogen hydroxide, to which a drop of litmus test-solution has been added, and which has been neutralized with normal sodium hydroxide solution. After the reaction has ceased and the foaming has subsided, rinse the funnel and sides of the vessel with distilled water, and, after allowing it to stand 10 minutes, titrate back with normal sulphuric acid, using litmus test-solution as indicator. Subtract the number of cubic centimeters of normal sulphuric acid used from 50 (the number of Cc. of normal sodium hydroxide solution employed), multiply the remainder by 2.979, and divide the product by the weight of the solution taken; the quotient represents the percentage of absolute formaldehyde in the liquid.

This method of estimating formaldehyde quantitatively was suggested by Blank and Finkenbeiner in 1898, and involves the oxidation of formaldehyde to formic acid at the expense of the hydrogen dioxide added, the acid being neutralized by the alkali hydroxide and hydrogen being eliminated according to the following reaction: $2H.CHO + H_2O_2 + 2NaOH = 2H.COONa + 2H_2O + H_2$. Since 59.58 Gm. of formaldehyde will yield by oxidation sufficient formic acid to neutralize 79.52 Gm. of sodium hydroxide, as shown by the equation above, each cubic centimetre of normal sodium hydroxide solution neutralized by the newly formed formic acid, in the official test, corresponds to 0.02979 Gm. of formaldehyde.

Action and Uses.—This preparation is employed in medicine for its powerful antiseptic properties. By heat it may be converted into a gas, which latter is employed for the purpose of disinfecting rooms previously exposed to contagion. One pint of the solution when converted into vapor is considered sufficient to disinfect a room containing 500 cubic feet. It has been largely, but unlawfully, used for preserving milk and other foods which are prone to deteriorate. When largely diluted, it may be employed intravenously for the purpose of combating septicæmia. Diluted with from 3 to 10 parts of water, it is said to retard the growth of uterine cancer, but its employment is quite painful and not wholly unattended with danger.

Formaldehydum. *Formic aldehyde, Methyl aldehyde*, E.; *Formaldehyd, Ameisenaldehyd*, G. HCHO or CH_2O.—This compound, which was discovered by A. W. Hofmann in 1868, is at ordinary temperature a colorless gas possessing a strong, pungent, irritating odor. It is condensable to a colorless liquid which boils at —21° C. (5.8° F.), and which if kept at —20° C. (—4° F.) readily changes to the solid insoluble polymeric form. Aqueous solutions of formaldehyde containing 50 per cent. of the gas are obtainable, but polymerize readily, and hence commercial solutions are made of 35 or 40 per cent. strength. Formaldehyde is a strong reducing agent, readily reducing silver, gold, and copper from aqueous alkaline solutions. It gives the reactions common to aldehydes and forms many condensation-products. It enters into direct combination with albumin, casein, gelatin, agar-agar, starch, dextrin, acids, and alkali hydroxides, and enters into quantitative reaction with ammonia, forming hexamethylenetetramine, according to the equation $6CH_2O + 4NH_3 = (CH_2)_6N_4 + 6H_2O$. Heated with dilute sodium hydroxide solution, formaldehyde is converted into formic acid. Dilute solutions of formaldehyde shaken with calcium hydroxide produce formose, which is convertible into isoformose on continued boiling of the solution in the presence of tin.

Formaldehyde is a powerful disinfectant, antiseptic, and preservative. Commercially it is extensively used for these purposes, and lately has been found useful in the tanning of hides and skins. Besides the properties of formaldehyde already mentioned above under

Liquor Formaldehydi, the following reactions are available for its recognition in very dilute solutions: To the solution add a few drops of a weak solution of phenylhydrazine hydrochloride and a few drops of a fresh solution of sodium nitroprusside, then a few drops of concentrated solution of sodium hydroxide, when in the presence of formaldehyde a blue color will be developed (Rimini). About 0.05 Gm. of resorcin is added to the suspected solution and the latter then mixed with an equal volume of 50 per cent. sodium hydroxide solution and the mixture heated to boiling, when a permanent red color develops in the presence of formaldehyde (Lebbin). Hehner's test for formaldehyde in milk is a very delicate reaction: Dilute the milk with an equal volume of water and superimpose it upon 94 per cent. sulphuric acid containing a trace of ferric chloride. A violet-blue coloration will appear at the point of contact of the two liquids.

Derivatives of Formaldehyde.—Amyloform.—A white, odorless, innocuous, non-irritant powder, insoluble in water, not decomposed by heat under 180° C. (356° F.), but decomposed by acids and alkalies with liberation of formaldehyde. It is prepared by making a dilute mixture of starch in water, and then adding a strong solution of formaldehyde. After allowing the mixture to stand for some time it is heated to boiling, then evaporated to dryness, and the residue pulverized. Recommended as a substitute for iodoform.

Glutoform.—*Glutol, Formaldehyde-gelatin, Collaform.*—A white insoluble powder prepared by the action of formaldehyde upon a solution of gelatin. Various methods are employed. Schroeder directs 50 parts of gelatin to be dissolved in 50 parts of boiling water, and when the solution is complete, to add 2 Cc. of formaldehyde, to stir thoroughly the agglutinated mass, transfer it to a cold dish, and to pour over it a solution of formaldehyde. After allowing it to react for some hours the solid residue is dried and pulverized. Recommended as a germicidal dusting-powder.

Geoform.—*Kreoform.*—A condensation-product from the action of formaldehyde upon guaiacol. A colorless, tasteless, non-irritant powder, insoluble in water, soluble in alcohol and ether, and in aqueous alkali hydroxide solutions, from which last it is reprecipitated by acids. Recommended as a germicidal dusting powder.

Paraform.—*Paraformaldehyde, Triformol, Trioxymethylene.* $(CH_2O)_3$.—A white, amorphous to crystalline powder, insoluble in cold water, soluble in boiling water and in solutions of fixed alkali hydroxides. With calcium hydroxide it yields formic acid and a fermentable sugar, formose. It combines with the haloid acids. It is slowly sublimable at 100° C. (212° F.), but does not melt below 152° C. (305.6° F.). The sublimed paraform melts at 172° C. (341.6° F.) (Tollens). At higher temperatures it is decomposed into formaldehyde. Employed in surgery for its antiseptic properties.

Thymoform. $[C_6H_3(CH_3).C_3H_7O]_2.CH_2$.—A yellowish, almost tasteless powder, of a slight thymol odor, insoluble in water, glycerin, and petroleum ether. Soluble in alcohol, ether, chloroform, carbon disulphide, and fixed oils. Iodothymoform is prepared by iodizing thymoform. It is a yellow powder melting at 150° C. (302° F.), insoluble in water and glycerin, but soluble in alcohol, ether, chloroform, and fixed oils.

Protogen.—*Ovoprotogen.*—A yellow powder, used as a food-product, and obtained by the action of formaldehyde upon white of egg.

LIQUOR HYDRARGYRI NITRATIS, *U. S.*—Solution of Mercuric Nitrate.

Liquor hydrargyri nitratis acidus, Br.; *Liquor hydrargyri nitrici oxydati.—Acid solution of nitrate of mercury, Solution of pernitrate of mercury*, E.; *Azotate (Nitrate) mercurique liquide, Nitrate acide (Pernitrate) de mercure*, Fr.; *Mercurinitratlösung, Quecksilberoxydnitratlösung*, G.

A liquid containing about 60 per cent. of mercuric nitrate, $Hg(NO_3)_2$, together with about 11 per cent. of free nitric acid.—U. S.

Preparation.—Red mercuric oxide, 40 Gm.; nitric acid, 45 Gm.; distilled water, 15 Gm.; to make 100 Gm. Mix the nitric acid with the distilled water, and dissolve the red mercuric oxide in the mixture. Keep the solution in glass-stoppered bottles.—U. S.

The foregoing formula will yield a little over 1½ fluidounces (1.61 +) of solution.

Take of mercury, 4 ounces; nitric acid, 5 fluidounces; distilled water, 1½ fluidounces. Mix the nitric acid with water in a flask, and dissolve the mercury in the mixture without the application of heat. Boil gently for 15 minutes, cool, and preserve the solution, which should weigh about 3 times the quantity of the mercury employed, in a stoppered bottle not exposed to the light.—Br.

Mercury, 100 parts; nitric acid, 150 parts; water, 50 parts. Dissolve and evaporate to 225 parts.—Fr. Cod.

The mercury is dissolved in the last two processes by the action of nitric acid, with elimination of red nitrous vapors, to form mercuric nitrate; $3Hg_2 + 16HNO_3$ yields $6Hg(NO_3)_2 + 4NO + 8H_2O$. It is necessary to apply some heat, particularly at the close of the reaction, to convert into mercuric any mercurous salt which may be present. The United States process yields the same solution more rapidly, and involves simply a combination of the mercuric oxide with nitric acid, water being liberated; $HgO + 2HNO_3$ yields $Hg(NO_3)_2 + H_2O$. The three solutions do not differ materially from one another, representing respectively 35 (Br.), 40 (U. S.), 43 (Fr.) per cent. of mercuric oxide.

Properties.—The solution is colorless, and has a slight odor of nitric acid, a strong acid reaction, and a caustic and metallic taste. Its specific gravity is about 2.086 at 25° C. (77° F.) U. S. P., about 2.0, Br. A crystal of ferrous sulphate dropped into it soon becomes surrounded with a dark-colored liquid (nitrate). Dropped upon copper, a deposit of mercury is at once produced, and the diluted solution gives a yellow precipitate with sodium or potassium hydroxide solution and a scarlet-red precipitate with potassium iodide; this latter precipitate is soluble in an excess of the precipitant. Nearly one-fourth of the nitric acid is uncombined, and prevents the separation of a basic salt on dilution with water. Evaporated by heat on a glass or porcelain dish, a white salt is left, which on the further application of heat is decomposed, assuming a yellow, red, and brown color, and is finally completely volatilized. The solution, mixed with alcohol and heated, produces *fulminating mercury*, which is very explosive.

Tests.—The characters given are sufficient to determine the quality of the preparation. On the addition of water no precipitation should occur (free nitric acid). Diluted hydrochloric acid should occasion no precipitate, potassa solution a yellow (not black), and potassium iodide a scarlet-red (not yellow or green) precipitate (absence of mercurous salt).

Action and Uses.—This solution is employed locally only when a powerfully caustic action is desired. It destroys the parts with which it comes in contact, and produces a zone of inflammation around the cauterized area. It may be applied to chancres, cancers, lupus, small boils, acne, and erosions of the uterine cervix. If accidentally taken in overdose, it produces burning pain in the mouth, œsophagus, and gastro-intestinal tract, with nausea, vomiting, purging, and collapse followed by death. Poisoning by this solution should be treated by the administration of mild alkalies, demulcent drinks, opium, and stimulants as needed.

Allied Preparations. MILLON'S TEST SOLUTION.—Dissolve with a gentle heat mercury in an equal weight of strong nitric acid, dilute the solution with twice its bulk of water, and decant from the precipitate; the liquid must contain some free nitric and nitrous acid. A solution of nearly the same mercury strength, but containing no nitrous acid, is obtained by diluting the pharmacopœial (U. S.) solution of mercuric nitrate with an equal bulk of water. Millon's reagent is used as a reagent for proteids, the mixture, as well as the precipitate, acquiring a red color on boiling.

HYDRARGYRI PROTONITRAS. *Nitras (azotas) hydrargyrosus*, Fr. Cod.—*Mercurous nitrate*, E.; *Azotate mercureux*, Fr.; *Mercuronitrat, Salpetersaures Quecksilberoxydul*, G.—Mercury, 4 parts; nitric acid, 3 parts; water, 1 part. After 24 hours collect the crystals, wash them with a little diluted nitric acid, and dry.—Fr. Cod. The salt forms colorless monoclinic plates or prisms having the composition $Hg_2(NO_3)_2 2H_2O$, molecular weight 559.4; it melts at 70° C. (158° F.), is completely soluble in a little warm water, but is by more water decomposed into a soluble acid and an insoluble basic salt; the solution imparts to the skin a purplish-red color, turning black.

LIQUOR HYDRARGYRI NITRICI OXYDULATI, S. HYDRARGYRUM OXYDULATUM SOLUTUM, S. LIQUOR BELLOSTII.—*Solution of mercurous nitrate*, E.; *Liqueur de Belloste*, Fr.; *Mercuronitratlösung*, G.—Dissolve without heat mercurous nitrate 100 parts in nitric acid 15 parts and water 885 parts. On exposure to the air oxidation to mercuric nitrate takes place.

LIQUOR HYDRARGYRI PERCHLORIDI, *Br.*—Solution of Mercuric Chloride.

Liquor hydrargyri bichloridi.—Solution of corrosive sublimate, E.; *Soluté de bichlorure de mercure*, Fr.; *Sublimatlösung*, G.

Preparation.—Take of mercuric chloride, 10 grains; distilled water, 1 pint (Imperial measure). Dissolve.—Br.

This is a colorless solution having the metallic taste of the salt from which it is made. It contains ½ grain of corrosive sublimate to the (Imperial) fluidounce.

Liqueur de Van Swieten, Fr. Cod., Van Swieten's Solution, is a solution of 1 part of corrosive sublimate in 100 parts of alcohol and 900 parts of water.

Action and Uses.—This solution may be taken in doses of from ½ to 2 fluidrachms (2–8 Cc.).

LIQUOR IODI COMPOSITUS, *U. S.*—Compound Solution of Iodine.

Lugol's Solution, E.; *Soluté iodurê de Lugol*, Fr.; *Lugolsche Jodlösung*, G.

An aqueous solution, which should contain not less than 5 per cent. of iodine and 10 per cent. of potassium iodide.—U. S.

Preparation.—Iodine, 5 Gm.; potassium iodide, 10 Gm.; distilled water, 85 Gm.; to make 1000 Gm. Dissolve the iodine and potassium iodide in the distilled water. Keep the solution in well-stoppered bottles.—U. S.

To prepare 4 fluidounces of Lugol's Solution 108 grains of iodine and 216 grains of potassium iodide should be dissolved in 4 ounces of distilled water.

Solutions of potassium iodide dissolve iodine in different proportions, weak solutions taking up 1 atom of I for each molecule of KI, or 76.5 parts for 100 parts of the salt. The dissolved portion therefore has the composition KI_3.

Properties.—The solution is of a dark brown-red color, having the caustic taste of iodine and imparting to starch-paste a dark-blue color. When boiled, iodine is given off, but the whole of it does not volatilize until the liquid is evaporated to dryness and the residuary mass heated nearly to redness. When agitated with chloroform, ether, or carbon disulphide, the solution is decolorized. If 3 Gm. of the solution be diluted with about 20 Cc. of distilled water and boiled until colorless, and then allowed to cool, after adding 2 drops of potassium chromate test-solution, not less than 18 Cc. nor more than 18.4 Cc. of decinormal silver nitrate solution should be required to produce a permanent red color of silver chromate. If 6.3 Gm. of the solution be mixed with a few drops of starch test-solution, it should require for complete decoloration not less than 24.75 Cc. of tenth-normal sodium thiosulphate solution.

Action and Uses.—The medical properties of this solution depend principally upon the free Iodine (which see) which it contains. It may be employed in the treatment of constitutional syphilis, and is thought to be very servicable in those cases which fail to respond to potassium iodide. The ordinary dose is 5 minims (0.3 Cc.), corresponding to ¼ grain (0.015 Gm.) of iodine.

Allied Preparations.—Liquor Iodi Fortis, Br.—*Strong solution of iodine.*—This solution, which is almost identical with the liniment of iodine of the 1885 Br. P., is made by dissolving iodine, 1¼ ounces, and potassium iodide, ¾ ounce, in 1¼ fluidounces of distilled water, adding 90 per cent. alcohol 9 fluidounces, and shaking the mixture.

Liquor Iodi Causticus, N. F.—*Caustic solution of iodine; Churchill's iodine caustic.*—Iodine, 480 grains; potassium iodide, 960 grains; distilled water, 4 fluidounces.

Causticum Iodi.—*Lugol's Caustic.*—Iodine and potassium iodide, of each, 1 part; water, 2 parts. By substituting glycerin for the water, *Hebra's iodine caustic* is obtained.

LIQUOR MAGNESII CARBONATIS, *Br.*—Solution of Magnesium Carbonate.

Aqua magnesio-effervescens.—Fluid magnesia, E.; *Eau magnésienne, Magnésie liquide*, Fr.; *Magnesiawasser, Kohlensaure Magnesialösung*, G.

Preparation.—Take of magnesium sulphate, 2 ounces; sodium carbonate, 2½ ounces; distilled water, a sufficiency. Dissolve the two salts separately, each in ½ pint of water. Heat the solution of magnesium sulphate to the boiling-point, then add to it the solution of sodium carbonate, and boil them together until carbon dioxide ceases to be evolved. Collect the precipitated magnesium carbonate on a calico filter, and wash it with distilled water until the filtrate is free from sulphate. Mix the washed precipitate with a pint of distilled water, and, putting them into a suitable apparatus, pass into it pure washed carbon dioxide. Let the mixture remain in contact with excess of carbon dioxide, retained there under a pressure of about 3 atmospheres, for 24 hours or

longer; decant the solution, into which again pass carbon dioxide. Finally, keep the solution in bottles securely closed to prevent the escape of carbon dioxide. The solution contains about 10 grains of magnesium carbonate in a fluidounce.—Br.

The first part of the above process embraces the preparation of magnesium oxycarbonate, $4(MgCO_3).Mg(OH)_2$, which is the official Magnesii Carbonas. By the subsequent operation this is dissolved in water by the aid of carbon dioxide in excess, whereby magnesium carbonate, $MgCO_3$, and bicarbonate, MgH_2CO_3, are formed.

Properties and Tests.—It is a colorless solution, which should effervesce on opening the vessel, carbon dioxide escaping, and has a slightly acidulous taste, free from bitterness. When the solution is exposed to cold, prismatic crystals of magnesium carbonate, $MgCO_3.5H_2O$, appear, which on exposure to the air lose water and become $MgCO_3.3H_2O$. It should yield no characteristic reaction for sulphates. 20 Cc. evaporated to dryness afford a white residue of pure hydrous magnesium carbonate, which after being calcined weighs between 0.16 and 0.19 Gm. This residue is insoluble in water, and when dissolved in dilute acid responds to the tests for magnesium. —Br.

Action and Uses.—This slightly effervescent solution is employed as an antacid and laxative. Its taste is disagreeable, and it has no advantages over extemporaneous mixtures containing magnesia. The dose is from 1 to 2 fluidounces (30–60 Cc.).

LIQUOR MAGNESII CITRATIS, *U. S.*—Solution of Magnesium Citrate.

Liquor magnesii citrici.—Limonade au citrate de magnésie, Limonade purgative citro-magnésienne, Fr.; *Magnesiumcitratlösung, Magnesiumlimonade,* G.

Preparation.—Magnesium carbonate, 15 Gm.; citric acid, 33 Gm.; syrup of citric acid, 60 Cc.; potassium bicarbonate, in crystals, 2.5 Gm.; water, a sufficient quantity. Dissolve the citric acid in 120 Cc. of water, and, having added the magnesium carbonate, stir until it is dissolved. Filter the solution into a strong bottle of the capacity of 360 Cc., containing the syrup of citric acid. Then add sufficient water to nearly fill the bottle, drop in the potassium bicarbonate, and immediately close the bottle with a cork, which must be secured with twine. Lastly, shake the mixture occasionally until the potassium bicarbonate is dissolved.—U. S.

Effervescent solution of magnesium citrate has been the source of frequent annoyance to the pharmacist. The present official directions are an improvement on those of 1890 in ordering an increased quantity of citric acid, which will produce a solution less liable to deposit if kept on hand for some time, although of decidedly more acid taste. When magnesium carbonate and citric acid are brought together in the presence of water, carbon dioxide is generated and magnesium citrate is formed; the exact composition of the latter salt depends upon the amount of base or acid present. Normal magnesium citrate of the composition $Mg_3(C_6H_5O_7)_2$ is but slightly soluble in water, and crystallizes from its solutions with 14 molecules of water; it is formed whenever 10 molecules of citric acid are allowed to react with 3 molecules of official magnesium carbonate, as follows: $3[4(MgCO_3).Mg(OH)_2.5H_2O] + 10H_3C_6H_5O_7.H_2O = 5Mg_3(C_6H_5O_7)_2 + 12CO_2 + 43H_2O$. The acid magnesium citrate, $MgHC_6H_5O_7$, is very soluble in water, and is the compound aimed at by the formula of both pharmacopœias; it is produced by the following reaction: $4(MgCO_3).Mg(OH)_2.5H_2O + 5H_3C_6H_5O_7.H_2O = 5MgHC_6H_5O_7 + 4CO_2 + 16H_2O$, which shows that each molecule of official magnesium carbonate requires 5 molecules of citric acid. The 15 Gm. of magnesium carbonate ordered in the official formula require 21.61+ Gm. of citric acid to form the normal, or 32.43 Gm. to form the acid salt; the Pharmacopœia orders 33 Gm. of acid, of which only 31.85 Gm. are available for the magnesium salt, as the quantity of official syrup of citric acid ordered does not contain sufficient acid to decompose the 2.5 Gm. of potassium bicarbonate subsequently added. The official solution must contain, therefore, a mixture of acid and normal salts, the former largely predominating. If a solution of acid magnesium citrate only is desired which will not deposit in the course of time, the quantity of citric acid in the official formula must be increased to 33.58 (32.43 + 1.15) Gm., which includes the necessary amount of acid to supply the deficiency in the syrup stated above; this, however, produces a very acid liquid, and may be objected to by many persons on that account. A solution of normal magnesium citrate is admirably adapted for extemporaneous prepara-

tion, but it does not keep well for any length of time; the following formula, in which the quantity of magnesium carbonate directed by the Pharmacopœia has been retained, but the amount of citric acid has been reduced to five-sixths, will be found to yield a very satisfactory solution for use within 24 hours, and contains just sufficient excess of citric acid (2.24 Gm.) to make the taste agreeably acidulous: Mix 25 Gm. of citric acid in powder with 15 Gm. of magnesium carbonate, and add 180 Cc. of water; stir well until dissolved, and filter the solution into a strong bottle of 360 Cc. capacity containing 60 Cc. of syrup of citric acid. Add sufficient water to nearly fill the bottle, and drop in 2.5 Gm. of potassium bicarbonate in crystals; the bottle should be immediately closed with a perfect soft cork, which is to be secured with wire or twine. Finally, shake the bottle until all crystals are dissolved.

The Pharmacopœia orders plain water to be used, but if the solution is to be kept on hand, distilled, or, better yet, recently boiled and filtered, water will be found preferable, so as to avoid the formation of fungi. The potassium bicarbonate added is converted into neutral potassium citrate, the carbon dioxide which is eliminated remaining in solution. Magnesium carbonate is preferable to the oxide, as it is less apt to vary in composition; but if the latter is chosen, 6.23 Gm. of magnesium oxide may be used in place of 15 Gm. of the official carbonate.

To prepare the solution, 10 times (or any other convenient multiple) of the quantities of citric acid and magnesium carbonate are weighed out and mixed with the corresponding quantity of water; after the magnesia is dissolved, the liquid is passed through a paper filter, divided equally among the requisite number of bottles, each containing the necessary quantity of syrup; sufficient water is then added to each bottle, after which the potassium bicarbonate in crystals is dropped in. The corks are then inserted and securely fastened by twine, and the bottles laid upon their sides in a cool place. Prepared in this way, the crystals gradually dissolve in the syrup, and this slowly mixes with the lighter saline solution; if it be wanted for immediate use, by slight agitation the syrup and bicarbonate are dissolved in the aqueous fluid.

The solution is colorless, free from sediment, and of a pleasant acidulous taste, free from bitterness.

Action and Uses.—Solution of magnesium citrate is largely employed as a mild refrigerant cathartic. As a laxative it may be given in doses of from 4 to 6 fluidounces (120–180 Cc.). In order to obtain its full purgative effect an entire bottle (12 fluidounces—360 Cc.) should be administered either at once or in divided doses.

Allied Preparations.—LIQUOR MAGNESII ACETATIS.—*Solution of magnesium acetate*, E.; *Soluté d'acétate de magnésie*, Fr.; *Magnesiumacetatlösung*, G.—Renaud proposed a solution made by dissolving 40 parts of magnesium carbonate in sufficient acetic acid (137 parts), filtering, and evaporating to 100 parts. It is a colorless, syrupy liquid, having a bitterish taste less pleasant than the citrate, and containing nearly 60 per cent. of the dry acetate, $Mg(C_2H_3O_2)_2$ (molecular weight, 142.02). The dry salt is white, gum-like, very deliquescent, and freely soluble in water and alcohol.

ELIXIR MAGNESII ACETATIS.—Solution of magnesium acetate, 66 parts; alcohol, 14 parts; syrup of orange peel (or of lemon peel), 70 parts. This contains 25 per cent. of the dry salt, but less alcohol than directed by Garot's formula.

LIQUOR MORPHINÆ ACETATIS, *Br.*—Solution of Morphine Acetate.

Soluté d'acétate de morphine, Fr.; *Essigsaure Morphinlösung*, G.

Preparation.—Take of morphine acetate, 17½ grains; diluted acetic acid, 38 minims; alcohol (90 per cent.), 1 fluidounce; distilled water, a sufficient quantity. Mix the alcohol with an equal volume of distilled water, adding the diluted acetic acid; dissolve the morphine acetate in the mixture; dilute with sufficient distilled water to produce 4 fluidounces of solution.—Br.

The addition of diluted acetic acid is for the purpose of preventing dissociation of the morphine acetate; the alcohol likewise is intended to preserve the solution. 110 minims of the solution contain 1 grain of the morphine salt.

Uses.—See MORPHINA. Dose, from 15 to 30 minims (1–2 Cc.).

LIQUOR MORPHINÆ HYDROCHLORIDI, *Br.*—Solution of Morphine Hydrochloride.

Soluté de hydrochlorate de morphine, Fr.; *Salzsaure Morphinlösung*, G.

Preparation.—Take of morphine hydrochloride, 17½ grains; diluted hydrochloric acid, 38 minims; alcohol (90 per cent.), 1 fluidounce; distilled water, a sufficient quantity. Mix the alcohol with an equal volume of distilled water, adding the diluted hydrochloric acid; dissolve the morphine hydrochloride in the mixture; dilute with sufficient distilled water to produce 4 fluidounces of solution.—Br.

Although the presence of alcohol is essential for the prolonged preservation of the solution, the addition of diluted hydrochloric acid seems unnecessary. 110 minims of the solution contain 1 grain of morphine hydrochloride.

Uses.—See MORPHINA. Dose, from 15 to 30 minims (1–2 Cc.).

LIQUOR MORPHINÆ TARTRATIS, *Br.*—Solution of Morphine Tartrate.

Soluté de tartrate de morphine, F.; *Weinsteinsaure Morphinlösung*, G.

Preparation.—Take of morphine tartrate, 17½ grains; alcohol (90 per cent.), 1 fluidounce; distilled water, a sufficient quantity. Mix the alcohol with an equal volume of distilled water; dissolve the morphine tartrate in the mixture; add sufficient distilled water to produce 4 fluidounces.—Br.

This is a new preparation, morphine tartrate having been introduced on account of its greater solubility and stability. 110 minims of the solution contain 10 grains of the salt.

Action and Uses.—See MORPHINA. Dose, 15 to 30 minims (1–2 Cc.).

LIQUOR PANCREATIS, *Br.*—Pancreatic Solution.

Liquor Pancreaticus.—Soluté de pankreatine, Fr.; *Pankreatinlösung, Pankreasessenz*, G.

A liquid preparation containing the digestive principles of the fresh pancreas of the pig.

Preparation.—Pancreas, freed from fat and external membrane, and finely divided by trituration with washed sand or powdered pumice-stone, 5 ounces; alcohol (20 per cent.), 20 fluidounces. The pancreas should be added to the alcohol and digested in a closed vessel for 7 days, and then filtered. The preparation is most active when the animal from which it is obtained has been fed shortly before being killed.—Br.

Properties and Tests.—Pancreatic solution is a pale-yellowish liquid, 1 volume of which should completely peptonize 40 volumes of milk, as shown by the following test given in the Br. P.: If 2 Cc. of the solution, together with 0.2 Gm. of sodium bicarbonate and 20 Cc. of water, be added to 80 Cc. of milk, and the mixture be kept at a temperature of 45° C. (113° F.) for 1 hour, coagulation should no longer occur on the addition of nitric acid.

The *Liquor Pancreaticus* of the National Formulary differs from the preceding, being made as follows: pancreatin (U. S. P.), 17.5 Gm.; sodium bicarbonate, 50 Gm.; glycerin, 250 Cc.; compound spirit of cardamom, 35 Cc.; alcohol, 35 Cc.; purified talcum, 15 Gm.; water, a sufficient quantity to make 1000 Cc. Triturate the pancreatin and the sodium bicarbonate gradually with 650 Cc. of water; add the alcohol, compound spirit of cardamom, and purified talcum; mix them thoroughly by shaking, and pour the mixture upon a wetted filter, returning the first portions of the filtrate until it runs off clear. Wash the filter with sufficient water to obtain 750 Cc. of filtrate. To this add the glycerin. Each fluidrachm represents 1 grain of pancreatin.

Action and Uses.—See PANCREATINUM. Dose, 1 to 4 fluidrachms (4–16 Cc.).

LIQUOR PICIS CARBONIS, *Br.*—Solution of Coal Tar.

Soluté de goudron de houille, Fr.; *Kohlentheerlösung*, G.

Preparation.—Take of prepared coal tar, 4 ounces; quillaia bark, in No. 20 powder, 2 ounces; alcohol (90 per cent.), a sufficient quantity. Moisten the powdered quillaia bark with 1 fluidounce of the alcohol, and set aside for 24 hours in a closed vessel. Pack the mixture in a percolator, and pour over the contents, at intervals, further portions of alcohol, until 20 fluidounces of tincture have been obtained. To the tincture add the prepared coal tar, and digest at 48.9° C. (129° F.) for 2 days, occasionally stirring. Cool and decant or filter.—Br.

In the above process the saponin extracted from the soap bark by the alcohol is intended to keep the alcohol-soluble constituents of the coal tar in proper suspension when the solution is mixed with water for use. The prepared coal tar of the Br. P. is made by placing commercial coal tar in a shallow vessel, and maintaining it at a temperature of 48.9° C. (120° F.) for 1 hour, stirring frequently.

Action and Uses.—This preparation is employed externally in the treatment of many chronic skin affections.

LIQUOR PLUMBI SUBACETATIS, *U. S.*—Solution of Lead Subacetate.

Liquor Plumbi Subacetatis Fortis, Br.; *Liquor Plumbi Subacetici*, G.—*Acetum Plumbi, Acetum Saturni, Plumbum hydrico-aceticum solutum. Strong solution of lead subacetate, Goulard's Extract*, E.; *Sous-acétate de plomb liquide, Extrait de Saturne, Extrait de Goulard, Vinaigre de plomb*, Fr.; *Bleiessig*, G.

An aqueous liquid containing in solution not less than 25 per cent. of lead subacetate (approximately, $Pb_2O(C_2H_3O_2)_2$, 543.74), U. S. Specific gravity, 1.235 at 25° C. (77° F.), U. S.; 1.275, Br.; 1.235 to 1.240, P. G.; 1.32, Fr. Cod.

Preparation.—Lead acetate, 180 Gm.; lead oxide, 110 Gm.; distilled water, a sufficient quantity to make 1000 Gm. To the finely pulverized lead oxide contained in a mortar or porcelain dish, of about 1 liter capacity, add slowly and in portions, with constant trituration, the lead acetate, which has been previously dissolved in 700 Cc. of boiling distilled water, and boil the liquid for ½ hour, with occasional stirring. Finally, when cool, filter the solution, and add sufficient distilled water, which has been previously boiled and cooled, to make the finished product weigh 1000 Gm. Keep the solution in well-stoppered bottles.—U. S.

Take of lead acetate, 5 ounces; lead oxide, in powder, 3½ ounces; distilled water, a sufficient quantity. Boil the lead acetate and the lead oxide in 20 fluidounces of distilled water for half an hour, constantly stirring, and maintaining the volume of the liquid by occasional additions of distilled water; filter; when the liquid is cold, add sufficient distilled water to produce 1 pint (Imperial measure).—Br.

Lead acetate, 3 parts; lead oxide, 1 part; distilled water, 8 parts. Boil and preserve the weight.—Fr. Cod.

Lead acetate, 3 parts; lead oxide, 1 part; water, ½ part. Mix at the heat of a water-bath until the mixture has become white or nearly so; then add 9½ parts of water, set aside to settle, and filter.—P. G.

The slight increase in the quantities of lead acetate and oxide ordered in the U. S. P. formula was necessary to insure the presence of 25 per cent. of lead subacetate in the finished product. The solution may also be prepared by the process suggested by Haussmann, which is admirably adapted to the pharmacist's needs, and has the advantage of keeping the solution protected against atmospheric influences during its preparation: Pour 710 Cc. of distilled water, heated to boiling, into a strong bottle previously warmed and graduated at 710 Cc.; add quickly 180 Gm. of pure crystallized lead acetate in small pieces or granules, cork the bottle, and dissolve by gentle agitation. After solution of the salt, add in divided small portions 110 Gm. of lead oxide (97–99 per cent. pure), previously sifted, shaking the bottle after each addition. In about 10 minutes the yellow color of the lead oxide will disappear, and after 2 hours all reaction will have ceased. The mixture may then be filtered under cover. The resulting solution will measure about 810 Cc., or very nearly 27½ fluidounces.

Several basic lead acetates are known, the composition of which depends upon the

proportions in which the lead acetate and oxide are employed; thus the United States and British pharmacopœias, using the acetate and oxide in the proportion of their molecular weights, obtain in solution the basic compound indicated by the formula $Pb_2O(C_2H_3O_2)_2$, according to the equation $(Pb(C_2H_3O_2)_2 + 3H_2O) + PbO = Pb_2O(C_2H_3O_2)_2 + 3H_2O$; while the German and French pharmacopœias, directing the use of 3 parts of lead acetate to 1 of lead oxide, cause the production of a less basic compound, as shown by the equation $2(Pb(C_2H_3O_2)_2 + 3H_2O) + PbO = Pb_3O(C_2H_3O_2)_4 + 6H_2O$.

In the preparation of this solution other basic lead acetates, such as $Pb_3O_2(C_2H_3O_2)_2$, are also formed in small quantities in addition to those mentioned, and an insoluble white residue is always left, consisting of a very basic compound, probably having the composition $Pb_6O_5(C_2H_3O_2)_2$.

Properties.—Solution of lead subacetate is a colorless liquid having a sweet, astringent taste, and an alkaline reaction to test-paper. On exposure to air, or on being mixed with water containing air in solution, it yields a white film, and finally a white precipitate of basic lead carbonate. It unites readily with liquid and solid fats, and may be mixed with an equal volume of alcohol without precipitation. Added to a solution of acacia, it produces a dense white precipitate. In other respects the solution conforms to the reactions of lead acetate.

Tests.—After acidulating the solution with acetic acid, potassium ferrocyanide should produce a white precipitate free from any blue (iron) or red (copper) tint. When completely precipitated by an excess of sulphuric acid, the filtrate, on being evaporated to dryness, should leave no residue or only a very slight one (absence of other salts). When precipitated by an excess of ammonia, the filtrate should not have a blue color (absence of copper). "If 10 Gm. of the solution be diluted with distilled water, which has been previously boiled and cooled, to measure 100 Cc., and 13.6 (13.594) Cc. of this are added to 35 Cc. of tenth-normal oxalic acid solution, contained in a graduated cylinder, and after thorough shaking, the mixture is diluted with distilled water to measure 50 Cc., and again well shaken; then after the precipitate has settled, 10 Cc. of the clear solution, after diluting with about 50 Cc. of water and adding 5 Cc. of sulphuric acid, should not require more than 2 Cc. of tenth-normal potassium permanganate solution to produce a permanent pink tint. Each Cc. of tenth-normal oxalic acid solution required for the precipitation of the 13.6 Cc. of the diluted solution corresponding to 1 per cent. of lead subacetate present."—U. S. Each Gm. should require for complete precipitation 17 Cc. of tenth-normal sulphuric acid solution.—Br.

The reaction occurring in the official process of assay may be shown by the following equation: $Pb_2O(C_2H_3O_2)_2 + 2(H_2C_2O_4 + 2H_2O) = 2Pb(C_2O_4) + 2HC_2H_3O_2 + 5H_2O$. Hence each Cc. of tenth-normal oxalic acid will precipitate 0.013327 Gm. of lead subacetate, which corresponds practically to 1 per cent. of 1.36 Gm., the weight of the original solution taken. The number of Cc. of tenth-normal potassium permanganate required to produce a pink tint, multiplied by 5 (as only $\frac{1}{5}$ of the clear supernatant liquid is used), and then subtracted from 35 will indicate the exact quantity of tenth-normal oxalic acid required for precipitation of 1.36 Gm. ($\frac{1}{10}$ of 13.6 Cc.) solution used.

Action and Uses.—Goulard's Extract is employed locally as a sedative astringent in the treatment of sprains and bruises. As a rule, it should not be applied to incised wounds or abrasions of the skin. This solution is entirely too strong and requires dilution before applying. From ½ to 1 fluidounce (16–30 Cc.) added to 1 pint (480 Cc.) of water is usually sufficient.

LIQUOR PLUMBI SUBACETATIS DILUTUS, *U. S.*, *Br.*—Diluted Solution of Lead Subacetate.

Aqua Plumbi, P. G.; *Aqua Saturnina.—Lead Water*, E.; *Eau de Saturne, Eau blanche*, Fr.; *Bleiwasser, Kühlwasser*, G.

An aqueous liquid, which should contain about 1 per cent. of lead subacetate.—U. S.

Preparation.—Solution of lead subacetate, 40 Gm.; distilled water, a sufficient quantity to make 1000 Gm. Mix the solution of lead subacetate with sufficient distilled water, previously boiled and cooled, to make the product weigh 1000 Gm.—U. S.

To prepare a pint of lead water, 260 minims of solution of lead subacetate should be mixed with sufficient distilled water, previously boiled, to make 16 fluidounces.

Take of strong solution of lead subacetate, 2 fluidrachms; alcohol (90 per cent.), 2 fluidrachms; distilled water, a sufficient quantity. Mix the alcohol with 19½ fluidounces of recently boiled and cooled distilled water; add the strong solution of lead subacetate and shake.—Br.

The use of distilled water does not prevent the mixture from becoming turbid at once, the carbon dioxide held in solution or contained in the atmosphere producing lead carbonate; this gas is therefore expelled by the previous boiling of water. Since, however, the decomposition will again take place when exposed to the atmosphere, it is best to prepare lead water only in small quantities; for preparing 4 fluidounces of it 65 minims of Goulard's Extract are required; the French and German Pharmacopœias order 2 per cent.

The solution should be kept in well-stoppered bottles.

The terms *Aqua Plumbi Goulardi; Goulard's Lead Water, Goulard's Lotion, Goulard Water*, E.; *Eau de Goulard*, Fr.; *Goulard'sches Wasser*, G.; are applied to dilute solution of lead subacetate containing alcohol, as in the case of the British formula above.

Action and Uses.—This solution possesses the same properties as Goulard's Extract, but in a milder degree. As a rule it is too weak to be of any material benefit.

LIQUOR POTASSII ARSENITIS, *U. S.*—Solution of Potassium Arsenite.

Liquor arsenicalis, Br.; *Liquor kalii arsenicosi*, P. G.; *Solutio arsenicalis Fowleri, Kali arsenicosum solutum.—Arsenical Solution, Fowler's Solution*, E.; *Liqueur (solution) arsenicale de Fowler*, Fr.; *Fowlersche Tropfen*, G.

An aqueous solution, which should contain potassium arsenite corresponding to 1 per cent. of arsenic trioxide.—U. S.

Preparation.—Arsenic trioxide, in fine powder, 10 Gm.; potassium bicarbonate, 20 Gm.; compound tincture of lavender, 30 Gm.; distilled water, a sufficient quantity to make 1000 Gm. Boil the arsenic trioxide and potassium bicarbonate with 100 Cc. of distilled water, in a tared dish, until solution has been effected. Then add sufficient distilled water to make the solution, when cold, measure 970 Gm., and lastly, add the compound tincture of lavender. Filter through paper.—U. S.

To prepare ½ pint of Fowler's Solution, 37 grains of arsenic trioxide and 74 grains of potassium bicarbonate should be boiled with 6 fluidrachms of distilled water until dissolved; when cool, sufficient distilled water should be added to bring the volume up to 7¾ fluidounces, and finally ¼ fluidounce of compound spirit of lavender is to be added.

Take of arsenious anhydride, in powder, and potassium carbonate, each, 87½ grains; compound tincture of lavender, 5 fluidrachms; distilled water, a sufficient quantity. Heat the arsenious anhydride and the potassium carbonate with 10 fluidounces of distilled water in a 1 pint flask until a clear solution is obtained, cool; add the compound tincture of lavender and sufficient distilled water to produce 1 pint (Imperial measure) of the solution.—Br.

The U. S. P. very properly directs the mixture of potassium bicarbonate and arsenic trioxide to be boiled in a small quantity of water, whereby combination and solution are readily effected. The solution is most conveniently prepared in a test-tube of sufficient capacity or a small flask having a long neck, so as to lessen evaporation of the water. The exact nature of the compound in solution is somewhat in doubt, some authorities believing that when 1 molecule of arsenic trioxide and 4 molecules of acid potassium carbonate are brought together with water, as in the official process, secondary potassium ortho-arsenite, K_2HAsO_3, is formed; others claim that primary potassium ortho-arsenite, KH_2AsO_3, is produced; while still others assert that potassium meta-arsenite, $KAsO_2$, only is formed, as in the preparations of the British and German pharmacopœias made with equal weights of arsenic trioxide and normal potassium carbonate. Some authorities even claim that the solution is not that of a definite arsenical compound at all, but simply a solution of the arsenous acid in the alkaline liquid, and that the U. S. P. solution will likewise be changed to this condition by the absorption of carbon dioxide from the atmosphere. Solution of potassium arsenite is likely to develop fungi in the course of time, and if an excess of alkali be present, as in the

British and German preparations, the arsenous acid is gradually converted into arsenic acid; it is, therefore, better not to keep the solution on hand in large quantities. While the preparations of the United States and British pharmacopœias are colored reddish by the compound tincture of lavender added, those of the German and French pharmacopœias are colorless.

The amount of arsenic trioxide represented in the solution may be conveniently ascertained by means of iodine, using starch paste as an indicator. The official tests are as follows: If 24.6 Cc. of the solution of potassium arsenite be diluted with water to 100 Cc., the mixture very slightly acidified wtih diluted hydrochloric acid, and then made alkaline with 2 Gm. of sodium bicarbonate, it should require not less than 50 Cc. of tenth-normal iodine solution to produce a permanent yellow tint (corresponding to 1 Gm. of arsenic trioxide in 100 Cc. of the solution).—U. S. 25 Cc. of the solution, neutralized with hydrochloric acid and diluted with water, should discharge the color of 50.8 to 50.9 Cc. of volumetric solution of iodine, the presence of a slight excess of sodium bicarbonate being maintained throughout the operation.—Br.

The addition of sodium bicarbonate in the official tests is for the purpose of neutralizing the newly formed arsenic and hydriodic acids, thus preventing decomposition of the latter by the former, which would vitiate the results by constantly liberating iodine.

Uses.—The employment of this solution is fully discussed under ARSENI TRIOXIDUM (which see). The beginning dose is from 1 to 5 minims (0.05–0.3 Cc.), which amount may be gradually increased until its physiological effects are observed.

LIQUOR POTASSII CITRATIS, *U. S.*—Solution of Potassium Citrate.

Mistura potassii citratis; Liquor kali citrici.—Citrate de potasse liquide, Fr.; *Kaliumcitratlösung*, G.

An aqueous liquid, containing in solution not less than 8 per cent. of anhydrous potassium citrate, with small amounts of citric and carbonic acids.—U. S.

Preparation.—Citric acid, 6 Gm.; potassium bicarbonate, 8 Gm.; water, a sufficient quantity. Dissolve the citric acid and the potassium bicarbonate each in 40 Cc. of water. Filter the solutions separately, and wash the filters with sufficient water to obtain in each case 50 Cc. of solution. Finally, mix the two solutions, and when effervescence has nearly ceased, transfer the liquid to a bottle. This preparation should be freshly made when wanted.—U. S.

To make 4 fluidounces of the official solution use 112 grains of citric acid and 154 grains of potassium bicarbonate, dissolving each separately in 2 ounces of water.

This solution of potassium citrate differs from Mistura Potassii Citratis, U. S. 1880, in the absence of the yellowish color and the agreeable lemon flavor. It has a mildly saline and pleasant acidulous taste. "If 10.14 Gm. of solution of potassium citrate be evaporated to dryness and then thoroughly carbonized at a temperature not exceeding a low red heat, and the residue extracted with boiling distilled water until the washings cease to react with methyl-orange test-solution, the filtrate should require for complete neutralization not less than 16 Cc. of half-normal sulphuric acid, methyl-orange test-solution being used as indicator (each Cc. of the half-normal sulphuric acid consumed representing 0.5 per cent. of anhydrous potassium citrate)."—U. S.

The direction to make the solution fresh as wanted is a commendable one, since aqueous solutions of citric acid undergo decomposition.

POTIO RIVERI, P. G., is less than one-third the strength of the preceding; it is made from citric acid 4 parts, water 190 parts, and crystallized sodium carbonate 9 parts.

POTIO DE RIVIERE, Fr. Cod. Dissolve citric acid and potassium bicarbonate, of each 2 Gm., separately in water 50 Gm., and syrup 15 Gm.; the solutions are often dispensed in separate vials.

Action and Uses.—This excellent refrigerant diaphoretic is largely employed in the treatment of fevers when the skin is hot and dry. It is largely used in treating the fevers of infants, and its efficacy is frequently increased by the addition of small doses of spirit of nitrous ether and tincture of aconite. Neutral mixture, which is prepared by substituting a solution consisting of equal parts of water and lemon-juice for the solution of citric acid, is much more agreeable to the taste. The dose is from $\frac{1}{2}$ to 1 fluidounce (16–30 Cc.).

LIQUOR POTASSII HYDROXIDI, *U. S.*—Solution of Potassium Hydroxide.

Liquor potassæ, Br. (U. S., 1890); *Liquor kali caustici*, P. G.; *Lixivium causticum.—Solution of potassa, Solution of potash*, E.; *Potasse caustique liquide, Lessive caustique*, Fr.; *Kalilauge, Ætzkalilauge*, G.

An aqueous solution of potassium hydroxide, KOH; molecular weight, 55–74—containing about 5 per cent. U. S., 5.85 per cent. Br., 15 per cent. P. G., of the hydroxide. Specific gravity, about 1.046 at 25° C. (77° F.) U. S., 1.058 Br., 1.126 to 1.130 P. G.

Preparation.—Potassium hydroxide, 60 Gm.; distilled water, 940 Gm. Dissolve the potassium hydroxide in the distilled water.

The potassium hydroxide used in this process should be of the full strength and quality directed by the Pharmacopœia (85 per cent.). Potassium hydroxide of any other strength, however, may be used, if a proportionately larger or smaller quantity be taken; the proper amount for the above formula being ascertained by dividing 5100 by the percentage of absolute potassium hydroxide contained therein. Solution of potassium hydroxide should be kept in bottles made of green glass, and provided with glass stoppers coated with paraffin or petrolatum.—U. S.

To prepare 1 pint of solution of potassa 450 grains of the official potassium hydroxide may be dissolved in sufficient distilled water to obtain 16 fluidounces of finished product.

The Br. P. no longer gives a method of preparation for this solution.

Solution of potassium hydroxide is prepared on a large manufacturing scale by gradually adding a boiling dilute solution of pure potassium carbonate to boiling milk of lime and boiling the mixture for 10 or 15 minutes to insure complete decomposition of the potassium salt. The mixture is strained through linen, the liquid set aside in well-closed vessels until clear, and then decanted and concentrated. The reaction occurring is between equal molecules of potassium carbonate and calcium hydroxide, 140 parts of the former requiring about 75 parts of the latter.

Properties.—Solution of potassium hydroxide is a clear and colorless liquid of the specific gravity stated above, and has a strong alkaline reaction and a very caustic taste. The slight peculiar odor which it usually has is due to its action upon organic bodies which may have been derived from the atmosphere. It dissolves wool, skin, and other animal and many vegetable substances, and decomposes fats, forming therewith soluble soaps. It attracts carbon dioxide from the air with great avidity, and must therefore be preserved in well-stoppered bottles. Green glass free from lead is best adapted for the purpose, but it is likewise somewhat decomposed by alkalies, which cause the stopper to become firmly fastened into the bottle unless protected by a thin layer of paraffin. Potassium hydroxide solution decomposes the salts of ammonium, of the metals, and of all the alkaloids, and induces the decomposition of tannin and its derivatives; a drop taken by a platinum loop and held in a non-luminous flame imparts to it a violet tint. As a test of identity, and considering the strong yellow color given by sodium compounds, the flame may be examined through blue glass to cut off the color of sodium. It differs from soda solution in yielding a white crystalline precipitate with excess of concentrated solution of tartaric acid, and a yellow one on the addition of hydrochloric acid and platinic chloride.

1.146	17	1.349	35	1.578	53		
1.155	18	1.361	36	1.590	54		

The table on page 913 by Gerlach shows the specific gravity at 15° C. (59° F.) of solutions containing from 1 to 70 per cent. of potassium hydroxide.

Tests.—Solution of potassium hydroxide should conform to the reactions and tests given under POTASSII HYDROXIDUM for an aqueous solution of the same. The U. S. P. demands that 28 (27.9) Gm. of solution of potassium hydroxide shall require about 25 Cc. of normal sulphuric acid for complete neutralization, methyl orange being used as an indicator, each Cc. of the acid corresponding to 0.2 per cent. of absolute potassium hydroxide. According to the Br. P., 9 Cc. of the solution should require for neutralization 10 Cc. of normal sulphuric acid, corresponding to 0.557 Gm. of KOH, which is equivalent to 5.85 per cent.

Action and Uses.—For the employment of this solution see POTASSII HYDROXIDUM.

LIQUOR POTASSII PERMANGANATIS, *Br.*—Solution of Potassium Permanganate.

Soluté de permanganate de potasse, Fr.; *Kaliumpermanganatlösung*, G.

Preparation.—Potassium permanganate, 87½ grains; distilled water, a sufficient quantity. Dissolve the potassium permanganate in sufficient distilled water to produce 1 pint (Imperial measure) of the solution.—Br.

The solution, which contains 1 per cent. of potassium permanganate, is of a deep-purple color and shows the chemical behavior of the salt.

Action and Uses.—For the employment of this solution see POTASSII PERMANGANAS.

LIQUOR QUASSIÆ CONCENTRATUS, *Br.*—Concentrated Solution of Quassia.

Preparation.—Quassia wood, in No. 40 powder, 2 ounces; alcohol (20 per cent.), 22 fluidounces. Mix the quassia with 2 fluidounces of the alcohol; pack in a closed percolator; set aside for 3 days; percolate with the remaining alcohol, added in 10 equal portions at intervals of 12 hours; continue percolation with more alcohol until the product measures 1 pint (Imperial measure).—Br.

Concentrated solution of quassia is 8 times as strong as the infusion of quassia of the 1885 British Pharmacopœia, and keeps much better on account of the alcohol present.

Action and Uses.—This preparation is employed as a simple bitter (see QUASSIA).

LIQUOR RHEI CONCENTRATUS, *Br.*—Concentrated Solution of Rhubarb.

Preparation.—Rhubarb, in No. 5 powder, 10 ounces; alcohol (20 per cent.), 25 fluidounces. Moisten the rhubarb with 5 fluidounces of the alcohol; pack in a closed percolator; set aside for 3 days; percolate with the remaining alcohol added in 10 equal portions at intervals of 12 hours; continue percolation with more alcohol until the product measures 1 pint (Imperial measure).—Br.

This preparation, which may be looked upon as a weakly alcoholic 50 per cent. tincture of rhubarb, is about 20 times as strong as the former infusion of rhubarb, and is a decidedly more elegant looking preparation. It will precipitate upon standing.

Action and Uses.—The uses of solution of rhubarb are mentioned under RHEUM (which see).

LIQUOR SARSÆ COMPOSITUS CONCENTRATUS, *Br.*—Concentrated Compound Solution of Sarsaparilla.

Preparation.—Sarsaparilla, cut transversely and bruised, 20 ounces; sassafras root, in shavings, 2 ounces; guaiacum wood, in shavings, 2 ounces; dried liquorice root, bruised, 2 ounces; mezereon bark, cut small, 1 ounce; alcohol (90 per cent.), 4½ fluidounces; distilled water, a sufficient quantity. Infuse the sarsaparilla in 3 successive portions of 5 pints of the distilled water, for 1 hour each, at 71.1° C. (160° F.). Boil the other solid ingredients with distilled water until exhausted. Rapidly concentrate the mixed infusion and decoction until, when cold, the liquid measures 16 fluidounces;

add the alcohol; set aside for at least 14 days; filter. The product should measure 1 pint (Imperial measure).—Br.

Concentrated compound decoction of sarsaparilla would seem to be a more appropriate name for this preparation. It contains the same ingredients as the compound decoction of the preceding Br. P. and is 8 times as strong. The addition of alcohol causes the precipitation of some inert matter and subsequently preserves the liquid. The dose is from 2 to 8 fluidrachms (8–30 Cc.).

LIQUOR SENEGÆ CONCENTRATUS, *Br.*—Concentrated Solution of Senega.

Preparation.—Senega root, in No. 20 powder, 10 ounces; a mixture of 2 parts of alcohol (20 per cent.) and 1 part of alcohol (45 per cent.), 25 fluidounces. Moisten the senega with 4 fluidounces of the menstruum; pack in a closed percolator; set aside for 3 days; percolate with the remaining menstruum, added in 10 equal portions at intervals of 12 hours; continue percolation with more menstruum until the product measures 1 pint (Imperial measure).—Br.

Concentrated solution of senega is no doubt intended as a concentrated infusion of the drug, being 10 times as strong as the infusion of the 1885 British Pharmacopœia, made with boiling water. While the alcohol (about 28 per cent. in the finished product) is intended to preserve the solution, it cannot prevent the tendency to gelatinize caused by the presence of the pectin, which will even occur in much more strongly alcoholic preparations of the drug unless an alkali has been added. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

LIQUOR SENNÆ CONCENTRATUS, *Br.*—Concentrated Solution of Senna.

Preparation.—Senna, in No. 5 powder, 20 ounces; tincture of ginger, 2½ fluidounces; alcohol (90 per cent.), 2 fluidounces; distilled water, a sufficient quantity. Divide the senna into 3 equal portions; slightly moisten one portion with distilled water; pack in a percolator; set aside for 24 hours; pass distilled water through it until 5 fluidounces are obtained. Slightly moisten the second portion of senna with this liquid; pack in a percolator; set aside for 24 hours; percolate with the remainder of the liquid obtained from the first portion, and also with an additional 5 fluidounces obtained by passing more distilled water through the first portion. Repeat the process with the third portion of the senna, and continue successive percolation through the 3 portions, until a quantity of 16 fluidounces has been collected from the third percolator. Heat the liquid to 82.2° C. (180° F.) for 5 minutes; cool; set aside for 7 days; filter. Add the alcohol and tincture of ginger, previously mixed; set aside for 7 days; filter. The product should measure 1 pint (Imperial measure).—Br.

This concentrated infusion of senna is prepared by repercolation with cold water instead of boiling water, as directed for the infusion of 1885, and is 10 times as strong as the latter. Heating the watery percolate causes coagulation of albuminous matter, any mucilaginous matter taken up by the aqueous menstruum being precipitated by the alcoholic mixture afterward added. The ginger is intended as a corrective, to prevent griping. The dose is from ½ to 1 fluidrachm (2–4 Cc.).

LIQUOR SODÆ CHLORINATÆ, *U. S., Br.*—Solution of Chlorinated Soda.

Liquor sodæ chloratæ, U. S., 1890; *Liquor natri chlorati, Liquor natri hypochlorosi. Labarraque's Solution, Bleaching Solution*, E.; *Chlorure de soude liquide, Liqueur de Labarraque*, Fr.; *Chlornatronlösung, Bleichflüssigkeit*, G.

An aqueous solution of several chlorine compounds, chiefly NaClO and NaCl, and containing at least 2.4 per cent. by weight of available chlorine. The official solutions of the U. S. and Br. pharmacopœias are practically of the same strength, but that of the French Codex is less than one-third as strong.

Preparation.—Monohydrated sodium carbonate, 65 Gm.; chlorinated lime, 90 Gm.; water, a sufficient quantity to make 1000 Gm. Triturate the chlorinated lime (which should contain not less than 30 per cent. of available chlorine) with 200 Cc. of water,

gradually added, until a uniform mixture results. Allow the heavier particles to subside, and transfer the thinner, supernatant portion to a filter.. Then triturate the residue again with 200 Cc. of water, transfer the whole to the filter, and when the liquid has drained off, wash the filter and contents with 100 Cc. of water. Dissolve the monohydrated sodium carbonate in 300 Cc. of hot water, and add this solution to the previously obtained filtrate contained in a suitable vessel. Stir or shake the mixture thoroughly, and, if it should become gelatinous, warm the vessel until the precipitate subsides. Then transfer the mixture to a new filter, and, when no more liquid drains from it, wash the filter and contents with sufficient water to make the product weigh 1000 Gm. Keep the solution in well-stoppered bottles, protected from the light.—U. S.

To prepare 1 gallon of Labarraque's Solution, 9 avoirdupois ounces of monohydrated sodium carbonate, dissolved in 44 fluidounces of hot water, should be added to a solution of 13 avoirdupois ounces of chlorinated lime in 64 fluidounces of water (prepared as directed above); after the mixture has been well shaken and filtered, sufficient water should be passed through the filter to bring the volume of the solution up to 8 pints.

Take of chlorinated lime, 16 ounces; sodium carbonate, 24 ounces; distilled water, 1 gallon. Dissolve the sodium carbonate in 2 pints of the distilled water; thoroughly triturate the chlorinated lime with 6 pints of the water; mix the two liquids; filter. Keep the solution in a stoppered bottle in a cool and dark place.—Br.

Dry chlorinated lime, 100 Gm.; crystallized sodium carbonate, 200 Gm.; distilled water, 4500 Gm. Triturate the chlorinated lime in a porcelain mortar with a portion of the water, and separate by decantation the finest portion; triturate the residue, add more of the water, and decant as before; repeat this operation until two-thirds of the water has been used. Dissolve the sodium salt in the remaining water, mix the two liquids, let settle, and filter.—Fr. Cod.

The above processes yield the chlorinated soda by double decomposition of chlorinated lime with sodium carbonate, whereby calcium carbonate is precipitated, the chlorinated soda remaining in solution, together with the sodium chloride resulting from the decomposition of calcium chloride present in the lime compound and with the excess of sodium carbonate employed. The solution of sodium carbonate should be boiling hot when added to the mixture of chlorinated lime and water, the object being the precipitation of a dense calcium carbonate. If no heat is employed, the precipitate will be very light and retain a large proportion of the liquid. But heat should not be applied after the mixture has been made, since the solutions of chlorinated alkalies are decomposed thereby into chloride and chlorate, oxygen being at the same time evolved; in the presence of much free alkali the decomposition takes place less readily.

Properties.—The solution is clear and colorless, not pale-greenish, as described by the U. S. Pharmacopœia. Its specific gravity is 1.050 at 25° C. (77° F.). It has a feeble odor of chlorine, and a saline, somewhat styptic and sharp alkaline taste, and bleaches indigo, litmus, and vegetable colors like chlorine, but less energetically. With solution of ferrous sulphate it produces a brown precipitate of ferric hydroxide, and with solution of lead salt a brown one of lead dioxide; the color of both precipitates is lighter, from carbonate present, if an excess of the metallic salts be used. On the addition of hydrochloric acid, effervescence takes place, the gas consisting of carbon dioxide and chlorine, the latter resulting from the mutual reaction of the hydrochloric and hypochlorous acids; thus, $NaCl.NaClO + 2HCl = 2NaCl + HCl + HClO$, and $HCl + HClO = Cl_2 + H_2O$. It is upon the amount of this available chlorine that the value of this preparation depends.

Tests.—Solution of chlorinated soda is not precipitated by ammonium oxalate (absence of calcium). "If 7.04 Gm. of the solution be mixed with 50 Cc. of water, then 2 Gm. of potassium iodide and 10 Cc. of hydrochloric acid added, it should require not less than 48 Cc. of tenth-normal sodium thiosulphate solution to discharge the yellow color of the liquid (each Cc. of the volumetric solution corresponding to 0.05 per cent. of available chlorine)."—U. S. The chlorine set free liberates an equivalent quantity of iodine, which imparts a blue color to the solution containing starch, and this color disappears on the addition of the thiosulphate. The same process is used by the British Pharmacopœia, 3.5 Gm. of the chlorinated solution being mixed with a solution of 1 Gm. of potassium iodide in 100 Cc. of water and acidulated with 3 Cc. of hydrochloric acid; the brown color should be discharged by not less than 25 Cc. of the volumetric solution of sodium thiosulphate (2½ per cent. Cl).

Action and Uses.—This solution has been employed as a gastro-intestinal antiseptic and as a topical application to external ulcers of all kinds. The internal dose is 30 to 40 minims (2–2.6 Cc.), well diluted, repeated every 2 or 3 hours.

LIQUOR SODII ARSENATIS, *U. S., Br.*—Solution of Sodium Arsenate.

Soluté d'arséniate de soude, Fr.; *Arsensaure Natronlösung*, G.

An aqueous solution, which should contain sodium arsenate corresponding in amount to not less than 1 per cent. of exsiccated sodium arsenate.—U. S.

Preparation.—Exsiccated sodium arsenate, 1 Gm.; distilled water, a sufficient quantity to make 100 Gm. Dissolve the sodium arsenate in the distilled water. —U. S.

The above formula yields nearly 3½ fluidounces of solution, and hence each fluidrachm contains about ½ grain of the anhydrous salt.

Take of sodium arsenate, recently rendered anhydrous, 17½ grains; distilled water, a sufficient quantity. Dissolve the anhydrous sodium arsenate in sufficient distilled water to produce 4 fluidounces of solution.—Br.

The object of using anhydrous sodium arsenate in making this solution is to insure uniformity of strength in the finished product. The commercial salt may contain variable proportions of water of crystallization, ranging from 53 per cent. to less than 20 per cent., depending upon the care with which the salt has been preserved. The temperature used for desiccation should not be carried beyond 149° C. (300° F.) in order to avoid conversion of the ortho-arsenate into pyro-arsenate.

The solutions are colorless, and give the reactions of SODIUM ARSENATE (which see).

The Liqueur arsenicale de Pearson of the French Codex is made by dissolving 1 part of crystallized sodium arsenate in 600 parts of distilled water, which makes the product about one-tenth as strong as the above solutions. Pearson's Solution may therefore be readily prepared as directed in the National Formulary, by diluting the official solution of sodium arsenate with 9 times its volume of distilled water.

Action and Uses.—The value of this preparation is fully described under ARSENI TRIOXIDUM (which see). Dose, from 1 to 5 minims (0.05–0.3 Cc.).

LIQUOR SODII ETHYLATIS, *Br.*—Solution of Sodium Ethylate.

Solution of sodium alcoholate, E.; *Soluté d' ethylate de soude*, Fr.; *Natriumethylatlösung, Natriumalkoholatlösung*, G.

Preparation.—Sodium, clean and bright, 22 grains; absolute alcohol, 1 fluidounce. Cautiously dissolve the sodium in the absolute alcohol contained in a flask, the latter being kept cool by a stream of cold water.—Br.

Properties and Tests.—Solution of sodium ethylate is a colorless liquid of 0.867 specific gravity and syrupy consistence. It turns brown on keeping. When slightly heated, it boils and gives off alcoholic vapors, leaving a white residue which, on being strongly heated, becomes charred. If the white residue be mixed with water and heated, it yields ethyl alcohol, and the solution, on evaporation, leaves a white residue consisting almost wholly of caustic soda. The solution contains 18 per cent. of the solid sodium ethylate, and should be recently prepared.

When metallic sodium is brought in contact with absolute alcohol hydrogen is liberated and sodium ethylate is formed, as shown by the following equation: $C_2H_5OH + Na = C_2H_5ONa + H$. Ordinary alcohol cannot be used, since the water present will at once react with the sodium, forming sodium hydroxide or caustic soda.

Action and Uses.—This preparation is employed externally as a caustic. It is said to destroy tissue without the production of very much pain.

LIQUOR SODII HYDROXIDI, *U. S.*—Solution of Sodium Hydroxide.

Liquor sodæ, U. S., 1890.—*Liquor natri caustici*, P. G.; *Solution of soda, Solution of caustic soda*, E.; *Soude caustique liquide, Lessive des savonniers*, Fr.; *Natronlauge, Ätznatronlauge*, G.

An aqueous solution of sodium hydroxide, NaOH = 39.76, containing about 5

per cent. U. S., 15 per cent. P. G., 23 per cent. Fr. Cod., of the true hydroxide. Specific gravity of the official solutions: 1.056 at 25° C. (77° F.) U. S., 1.33 Fr. Cod., 1.168 to 1.172 P. G.

Preparation.—Sodium hydroxide, 56 Gm.; distilled water, 944 Gm. Dissolve the sodium hydroxide in the distilled water.

The sodium hydroxide used in this process should be of the full strength and quality directed by the Pharmacopœia (90 per cent.). Sodium hydroxide of any other strength, however, may be used if a proportionately larger or smaller quantity be taken; the proper amount for the above formula being ascertained by dividing 5040 by the percentage of absolute sodium hydroxide contained therein.—U. S.

To prepare 1 pint of solution of sodium hydroxide, 432 grains of the official sodium hydroxide may be dissolved in sufficient distilled water to obtain 16 fluidounces of solution.

Solution of sodium hydroxide may also be prepared by adding a boiling solution of sodium carbonate gradually to boiling milk of lime and boiling the mixture for a short time. When cold, the mixture is strained through muslin and set aside in well-stoppered vessels to become clear.

Properties.—Sodium hydroxide solution is a clear and colorless liquid of the density given above, and has a strong alkaline reaction and a very caustic taste; the peculiar slight odor which it usually has is solely due to the accidental presence of organic matters, which are likely to impart also a yellowish color. It dissolves various organic matters and tissues, and decomposes fats, forming soaps. It has a great affinity for carbon dioxide, and should be preserved in well-stoppered bottles made of glass free from lead, the stopper being protected by a thin layer of paraffin. In its chemical behavior it closely resembles potassa solution, but, unlike the latter, it does not yield a crystalline precipitate with excess of tartaric acid, except in concentrated solutions; with hydrochloric acid and platinum chloride it does not yield a yellow precipitate, and when, by means of a platinum wire, a drop of it is held in a non-luminous flame, an intense yellow color is imparted to the latter.

The following table by Gerlach shows the specific gravity at 15° C. (59° F.) of solutions containing from 1 to 70 per cent. of sodium hydroxide:

Spec. gravity at 15° C.	Percent. of NaOH.	Spec. gravity at 15° C.	Percent. of NaOH.	Spec. gravity at 15° C.	Percent. of NaOH.	Spec. gravity at 15° C.	Percent. of NaOH.
1.012	1	1.213	19	1.405	37	1.591	55
1.023	2	1.225	20	1.415	38	1.601	56
1.035	3	1.236	21	1.426	39	1.611	57
1.046	4	1.247	22	1.437	40	1.622	58
1.059	5	1.258	23	1.447	41	1.633	59
1.070	6	1.269	24	1.456	42	1.643	60
1.081	7	1.279	25	1.468	43	1.654	61
1.092	8	1.290	26	1.478	44	1.664	62
1.103	9	1.300	27	1.488	45	1.674	63
1.115	10	1.310	28	1.499	46	1.684	64
1.126	11	1.321	29	1.508	47	1.695	65
1.137	12	1.332	30	1.519	48	1.705	66
1.148	13	1.343	31	1.529	49	1.715	67
1.159	14	1.353	32	1.540	50	1.726	68
1.170	15	1.363	33	1.550	51	1.737	69
1.181	16	1.374	34	1.560	52	1.748	70
1.192	17	1.384	35	1.570	53		
1.202	18	1.395	36	1.580	54		

Tests.—Solution of sodium hydroxide should conform to the reaction and tests given under SODII HYDROXIDUM, for an aqueous solution of the same. The U. S. P. demands that 20 (19.9) Gm. of solution of sodium hydroxide shall require for complete neutralization about 25 Cc. of normal sulphuric acid, methyl orange being used as an indicator, each Cc. of the acid corresponding to 0.2 per cent. of absolute sodium hydroxide.

Action and Uses.—The employment of this preparation will be found under SODII HYDROXIDUM (which see). Dose, 10 to 30 minims (0.60–2 Cc.), well diluted.

LIQUOR SODII PHOSPHATIS COMPOSITUS, *U. S.*—Compound Solution of Sodium Phosphate.

Solutê de phosphate de soude composé, Fr.; *Zusammengesetzte Natriumphosphatlösung*, G.

Preparation.—Sodium phosphate, uneffloresced crystals, 1000 Gm.; sodium nitrate, 40 Gm.; citric acid, 130 Gm.; distilled water, a sufficient quantity to make 1000 Cc. Triturate the sodium phosphate and sodium nitrate in a mortar, with the citric acid, until completely liquefied, then add sufficient distilled water to make the product measure 1000 Cc. Filter the liquid. Keep the solution in well-stoppered bottles, in a moderately warm place.—U. S.

To make 1 pint of compound solution of sodium phosphate, 1 pound and 303 grains of sodium phosphate, and 293 grains of sodium nitrate should be triturated with 914 grains of citric acid until liquefied, after which sufficient distilled water is added to produce exactly 1 pint of liquid.

It is essential that the sodium phosphate be used in the form of uneffloresced crystals, otherwise perfect liquefaction will not result. Although official sodium phosphate requires about 6 times its own weight of water for solution at ordinary temperature, when liquefied in its own water of crystallization by the aid of sodium nitrate and citric acid, but little water need be added to produce the official solution, which remains liquid even when exposed for some time in a moderately cold room. If some of the salt should crystallize out, it may be brought into solution again by placing the bottle in hot water and agitating the contents. The official solution contains 1 Gm. of crystallized sodium phosphate in each cubic centimetre, or a trifle over 57 grains in a fluidrachm.

Compound solution of sodium phosphate is a colorless liquid having the density of a thin syrup, and a not disagreeable acid taste. The presence of phosphoric, citric, and nitric acids may be demonstrated by the following reactions given in the Pharmacopœia: If to 1 Cc. of the solution, diluted with an equal volume of water, a slight excess of ammonia water, followed by 1 Cc. of magnesium mixture test-solution, be added, a white crystalline precipitate will be obtained (caused by phosphoric acid); if 1 Cc. of the solution, diluted with 5 Cc. of water, be mixed with an equal volume of sulphuric acid, and to the cooled mixture a crystal of ferrous sulphate be added, a dark-brown zone will appear around the crystal (caused by nitric acid); if 5 Cc. of the solution be neutralized with ammonia water, an excess of calcium chloride test-solution added, and the mixture filtered, the filtrate, upon boiling, should deposit a white precipitate (caused by citric acid).

Action and Uses.—Although this solution is an elegant pharmaceutical preparation, there is no good reason for its introduction into the Pharmacopœia. The addition of a small amount of lemon juice to an ordinary aqueous solution of sodium phosphate forms a more palatable and an equally efficacious method of administering the salt. The dose of the solution is from ½ to 2 fluidrachms (2–8 Cc.).

LIQUOR SODII SILICATIS.—Solution of Sodium Silicate.

Liquor natrii silicici, P. G.; *Vitrium solubile.—Liquid glass, Soluble glass*, E.; *Silicate de soude liquide, Verre soluble, Verre liquide*, Fr.; *Natriumsilikatlösung, Wasserglas, Natronwasserglaslösung*, G.

Origin.—The element *silicon* or *silicium* (Si; atomic weight, 28.2) is an important constituent of many minerals and rocks. *Rock-crystal* is pure silica or silicic oxide, SiO_2, and *quartz, sand, amethyst, chalcedony, agate, flint*, and other minerals are chiefly composed of the same oxide. A combination of this oxide with alkali and other bases became known at an early date with the discovery of glass; and about 1640, Van Helmont noticed that the compound of silex and salt of tartar (potassium carbonate) would liquefy in a damp atmosphere. This liquid became known as *Liquor silicum—Liquor of flints*, E.; *Liqueur des cailloux*, Fr.; *Kieselfeuchtigkeit*, G. The usefulness of such a solution for rendering inflammable substances incombustible was proved by J. N. Fuchs (1818). In its preparation soda was soon substituted for potash, and the designation "liquid" or "soluble glass" applied indiscriminately to both compounds, which are used in calico-printing, as an addition to cheap soaps, in fresco-painting, for manufacturing artificial stone, for cements, and for other purposes. In 1900, 65,302,901 pounds of

sodium silicate were manufactured in the United States, in addition to which 1,306,782 pounds were imported.

Preparation.—Sodium silicate is usually made by fusing together a mixture of 1 part of fine sand or powdered flint and 2 parts of exsiccated sodium carbonate, dissolving the product in boiling water, filtering, and evaporating; or 8 parts of exsiccated sodium carbonate, 15 parts of fine sand, and 1 part of charcoal are used, the latter merely serving as a means for facilitating the decomposition of the carbonate, the gas evolved being partly carbonic oxide. A mixture of soda and potash with silica is more rapidly fusible than the former. The proportion of the ingredients, however, is varied according to the use to be made of the compound, and a more glass-like and less readily soluble mass is obtained by the fusion of 2 parts of silica and 3 parts of calcined soda.

Properties.—Sodium silicate is a transparent, glass-like mass, which may be obtained in crystals, Na_2SiO_3, with variable amounts of water of crystallization. On exposure the salt becomes superficially opaque, and it is slowly soluble in boiling water; but the alkaline solution may be evaporated to a thick syrupy consistence without separating a deposit on cooling. The solution, as met with in commerce, usually contains about 10 to 12 per cent. of soda (NaOH), and 20 to 24 per cent. of silica (SiO_2), and is a transparent or semitransparent, colorless or yellowish, viscid liquid, which is inodorous, and has a saline and sharp alkaline taste and an alkaline reaction to test-paper. Its specific gravity varies between 1.30 and 1.40. On acidulating the solution with hydrochloric acid the mixture remains transparent, but the colorless silicic acid forms gradually a dense jelly. If the solution be previously diluted with 10 to 15 parts of water, the silicic acid liberated by the hydrochloric acid will remain dissolved or suspended until the liquid is boiled or evaporated. Alcohol added to the solution produces a gelatinous precipitate of sodium silicate. A drop of the liquid held in a non-luminous flame by means of a loop of platinum wire burns with the intense yellow color of sodium compounds.

Solution of sodium silicate should be preserved in glass or stone vessels, securely stoppered with cork or caoutchouc to prevent access of air and decomposition by carbon dioxide gas. Stoppers of glass or stone may be used, but should be well coated with paraffin to prevent their becoming cemented to the neck of the vessel.

Tests.—When mixed with an equal bulk of alcohol any caustic alkali present will remain in solution, and may be recognized by test-paper or estimated by volumetric solution of oxalic acid. On adding excess of hydrochloric acid to the solution, only a moderate effervescence should take place, showing that it has not been injuriously affected by exposure; and on evaporating the acid mixture to dryness a residue partly soluble in water should be left, which is not colored dark by hydrogen sulphide. Should the solution of sodium silicate be strongly alkaline, it may be boiled with gelatinous silicic acid, which will be dissolved by the free alkali.

Action and Uses.—This solution is employed by surgeons in the preparation of fracture-dressings and other mechanical appliances.

LIQUOR STRYCHNINÆ HYDROCHLORIDI, *Br.*—Solution of Strychnine Hydrochloride.

Liquor strychniæ.—Soluté de chlorhydrate de strychnine, Fr.; *Salzsaure Strychninlösung*, G.

Preparation.—Take of strychnine hydrochloride, 17½ grains; alcohol (90 per cent.), 1 fluidounce; distilled water, a sufficient quantity. Dissolve the strychnine hydrochloride in the alcohol mixed with sufficient distilled water to produce 4 fluidounces of solution.—Br.

110 minims of the solution contain 1 grain of strychnine hydrochloride. The presence of alcohol serves to keep the solution better.

Action and Uses.—For the employment of this preparation see STRYCHNINA.

LIQUOR THYROIDEI, *Br.*—Thyroid Solution.

Thyroid essence, Thyroid extract, E.; *Schilddrüsenessenz, Schilddrüsenextrakt*, G.

A liquid prepared from the fresh and healthy thyroid gland of the sheep.—Br.

The Br. P. gives the following directions for its preparation: Remove the external fat and connective tissue from thyroid glands taken from sheep immediately after kill-

ing; cut the glands across, and reject any that contain cysts, are hypertrophied, or are otherwise abnormal. Count the healthy glands that remain; slice them and bruise them thoroughly in a mortar; for each entire gland (consisting of two lobes) add 34 minims of glycerin and 34 minims of a 0.5 per cent. solution of phenol in distilled water; transfer the mixture, well stirred, to a flask, and close the neck with a plug of cotton-wool; allow it to stand for 24 hours; strain then through linen, with strong pressure; add to the strained liquid sufficient of the 0.5 per cent. solution of phenol to make 100 minims of the solution for each gland used.

Properties.—Thyroid Solution is a pinkish, turbid liquid, entirely free from odor of putrescence. It must be freshly prepared, and kept in well-stoppered, sterilized bottles.

In order that a perfectly satisfactory preparation may be obtained it is essential that every precaution be taken to avoid contamination with dirt, and that the glands are absolutely free from disease. The lobes of the thyroid gland frequently occur separate, and it should be borne in mind that 2 lobes constitute 1 gland. Carbolated water is used as a preservative, but according to White and Humphrey is inferior to chloroform water of the same strength for the purpose desired.

Action and Uses.—The value of this preparation is described in the article on THYROID GLAND (which see).

LIQUOR ZINCI CHLORIDI, *U. S., Br.*—Solution of Zinc Chloride.

Chlorure de zinc liquide, Solution de Burnett, Fr.; *Chlorzinklösung, Flüssiges Chlorzink,* G.

An aqueous solution of zinc chloride, $ZnCl_2$—containing about 50 per cent. by weight of the salt.

Preparation.—Zinc, granulated, 240 Gm.; hydrochloric acid, 840 Gm.; nitric acid, 12 Gm.; precipitated zinc carbonate, 12 Gm.; distilled water, a sufficient quantity. To the zinc, contained in a glass or porcelain vessel, add 150 Cc. of distilled water; then gradually add the hydrochloric acid, and digest, until the acid is saturated. Pour off the solution, add the nitric acid, evaporate the solution to dryness, and heat the dry mass to fusion at a temperature not exceeding 115° C. (239° F.). Let it cool, and dissolve it in a sufficient amount of distilled water to make the product weigh 1000 Gm. Then add the precipitated zinc carbonate, agitate the mixture occasionally during twenty-four hours, and then set it aside until it has become clear by subsidence. Finally, separate the clear solution by decantation or by means of a syphon.—U. S.

The above formula will yield about 22 fluidounces of solution.

The Br. P. directs that granulated zinc 1 pound be added to a mixture of 44 fluidounces of hydrochloric acid and 20 fluidounces of water, and a gentle heat applied as long as gas is evolved. The mixture is then boiled for one-half hour, supplying the water lost by evaporation, and allowed to cool. If upon testing a few drops of the liquid iron or lead be found present, the liquid is to be filtered and solution of chlorine added by degrees, with frequent agitation until the liquid acquires a permanent odor of chlorine; zinc carbonate is then added in small quantities at a time, with renewed agitation, until a brown sediment appears and the whole of the iron or lead is thus precipitated. Finally the liquid is filtered and evaporated to the bulk of 2 pints (Imperial measure).

Zinc dissolves in hydrochloric acid with the evolution of hydrogen gas, $Zn_2 + 4HCl$ yields $2ZnCl_2 + 2H_2$. The iron contained in the solution is first oxidized in the one case by nitric acid and in the other by chlorine gas. To avoid contamination with nitrate, the former solution is evaporated to dryness, redissolved in water, and then treated with zinc carbonate, whereby ferric oxide is precipitated. The process of the British Pharmacopœia arrives at the same result in a similar manner, except that an evaporation of the liquid to dryness is not necessary. 1 pound of zinc yields about 33½ ounces of zinc chloride, which are contained in 40 (Imperial) fluidounces of the solution. The specific gravity is stated to be 1.548 at 25° C. (77° F.) U. S., 1.530 Br.

Properties.—The solution is a colorless and inodorous liquid which has the disagreeable metallic taste of zinc salts, and an acid reaction, and is miscible with alcohol and water without producing a precipitate. It should conform to the reactions and tests given under ZINCI CHLORIDUM.

The French Codex directs 1 part of fused zinc chloride to be dissolved in 2 parts of

water, the solution to be of specific gravity 1.33. Burnett's liquid contained 200 grains of zinc in the Imperial fluidounce, and was stated to have the specific gravity 2.0 and to contain about 50 per cent. of $ZnCl_2$.

Action and Uses.—This solution is not employed in internal medicine. It was formerly used for disinfecting hospitals, ships, cesspools, etc.; but at present it is seldom employed.

LIQUORES.—Solutions.

Solutés, Fr.; *Lösungen*, G.

With the exception of infusions, decoctions, and syrups, and of those aqueous liquids containing volatile oils or gases, all aqueous solutions are, by the U. S. Pharmacopœia, designated *Liquores;* the British and some other pharmacopœias embrace under the same head also aqueous solutions of gases. The German Pharmacopœia is inconsistent in its designation, lime water, chlorine water, and lead water being placed among *Aquæ*, while ammonia water is regarded as a *liquor*. Gutta-percha solutions and blistering liquids alone have a menstruum other than water. Many saline solutions develop a cryptogamic vegetation altering the nature and properties of the dissolved compounds; this is particularly the case with phosphates in the presence of organic substances. through the rapid growth of an alga, *Hygrocrocis phosphaticus*, which, according to Jacquemaire (1888), is prevented by the presence of carbon dioxide in excess.

LITHII BENZOAS, *U. S.*—Lithium Benzoate.

Lithium benzoicum. — *Benzoate de lithine*, Fr.; *Lithiumbenzoat, Benzoesaures Lithium*, G.

Formula $LiC_7H_5O_2$. Molecular weight, 127.11.

It should contain not less than 98.5 per cent. of pure salt, and be kept in well-stoppered bottles.—U. S.

Preparation.—This salt is made by decomposing lithium carbonate with benzoic acid, and according to Shuttleworth (1875), it is most advantageous to add the acid to the carbonate. 100 grains of the latter are heated with 900 grains (2 fluidounces) of distilled water, when 330 grains of benzoic acid or a sufficient quantity of it is added in small portions until effervescence is no longer produced. The filtrate is evaporated to dryness with constant stirring, and the salt rubbed to powder, or the hot somewhat concentrated solution may be set aside to crystallize on spontaneous evaporation. The yield will be 346 grains.

Properties.—Lithium benzoate is a white salt, forming either a light crystalline powder or small glistening pearly scales, which feel greasy to the touch and are sometimes aggregated to moss-like forms. Berzelius stated the salt to be hygroscopic, but Shuttleworth, and afterward Raskowsky (1886), showed it to be permanent in the air. It has a slight odor, like that of medicinal benzoic acid, or if free from aromatic compounds is inodorous; its taste is alkaline, somewhat cooling and sweetish; its reaction to test-paper is slightly acid. It dissolves at 25° C. (77° F.) in 3 parts of water and in 13 parts of alcohol, and at the boiling temperature in 2.5 parts of water and 10 parts of alcohol (U. S.). The presence of sodium benzoate increases the solubility in water and lessens that in alcohol. When heated, the salt melts, and at a higher temperature chars and emits aromatic inflammable vapors of benzene and other decomposition-products of benzoic acid, a portion of the latter subliming unaltered; the black residue left contains charcoal and lithium carbonate. The aqueous solution of the salt is decomposed by mineral acids, but not by carbon dioxide, and yields with ferric chloride a flesh-colored precipitate soluble in hydrochloric acid and in alcohol.

Tests.—If an excess of hydrochloric acid be added to a concentrated aqueous solution of 0.6 Gm. of the salt, and the white precipitate of benzoic acid be filtered, thoroughly washed, and dried, it should respond to the tests of purity given under ACIDUM BENZOICUM. If the filtrate and washings from this precipitate be evaporated almost to dryness on a water-bath in a 50 Cc. flask, and 10 Cc. of amyl alcohol (boiling-point 132° C.) be added, and the mixture cautiously heated until the lower aqueous layer has evaporated, which may be facilitated by passing a current of air through the hot solution, then, after the addition of 3 drops of hydrochloric acid and boiling for 3 minutes, the

resulting insoluble residue should weigh not more than 0.004 Gm. (limit of other alkalies). This test and separation depends upon the fact that lithium chloride is soluble in amyl alcohol, while the chlorides of the other alkali metals are insoluble. If the benzoic acid be precipitated from 1 Gm. of the salt in 20 Cc. of water by an excess of hydrochloric acid, a portion of the filtrate, after rendering alkaline with ammonia water, should produce neither a turbidity nor precipitate, either before or after boiling (absence of iron, aluminum, etc.). Another portion of the filtrate should not be colored or made turbid by an equal volume of hydrogen sulphide solution, after standing corked at 35° C. (95° F.) for at least half an hour, either before or after rendering alkaline with ammonia water (absence of heavy metals). If 0.5 Gm. of the salt be thoroughly mixed with about 1 Gm. of powdered anhydrous ammonium sulphate, and cautiously ignited in a porcelain crucible, until of constant weight, the residue should weigh not less than 0.210 Gm., nor more than 0.216 Gm.—U. S.

In the last-mentioned test, lithium sulphate, Li_2SO_4, is formed, which is non-volatile, while ammonium benzoate volatilizes. Theoretically, 254.22 parts of pure lithium benzoate should leave a residue of 109.31 parts of sulphate, or 43 per cent.; hence 0.5 Gm. of the pure salt should leave a residue of 0.215 Gm. of sulphate. This figure falls between the minimum and maximum residue allowed by the Pharmacopœia. A residue greater than the theoretical may be caused by the presence of alkali metals, whose atomic weights are higher than those of lithium, as sodium or potassium.

Action and Uses.—Lithium benzoate has been employed as a substitute for Benzoic Acid (which see) in the treatment of gouty and rheumatic affections and calculous disorders. The dose is from 15 to 30 grains (1–2 Gm.), in solution.

LITHII BROMIDUM, *U. S.*—Lithium Bromide.

Lithium bromatum.—Bromure de lithium, Fr.; *Bromlithium, Lithiumbromid*, G.

Formula, LiBr. Molecular weight, 86.34.

Lithium bromide should be kept in well-stoppered bottles, and should contain not less than 97 per cent. of pure salt when well dried.—U. S.

Preparation.—Yvon (1875) prepared the salt by dissolving lithium carbonate in hydrobromic acid and evaporating; or, 37 Gm. of the carbonate are converted into neutral sulphate, dissolved in a small portion of water, and mixed with a concentrated aqueous solution of 119 Gm. of potassium bromide; the mixture is well stirred, the liquid separated by filtration, evaporated to dryness, and treated with alcohol, which leaves potassium sulphate undissolved; the alcoholic solution is evaporated to dryness. A convenient method for preparing the salt consists in forming, first, ferrous bromide by gradually adding 399 grains of bromine to 300 grains of iron and 900 grains (2 fluidounces) of water; the green solution is filtered, heated, and in a flask agitated with 186 grains of lithium carbonate; when cool, the liquid is filtered and evaporated, yielding 434 grains of lithium bromide. Lithium bromide may be obtained in crystals by evaporating its syrupy solution over sulphuric acid. The anhydrous salt contains nearly 92 per cent. of bromine.

Properties.—Lithium bromide is a very deliquescent salt, and on this account not readily obtainable in crystals, but is usually kept in the form of a white powder more or less granular. It is inodorous, and has a somewhat pungent (sharp, U. S.) and bitterish taste and a neutral reaction. It imparts a crimson color to flame, melts at a dull-red heat, and at a white heat is slowly volatilized. It is freely soluble in alcohol, also in ether, and dissolves at 25° C. (77° F.) in 0.6 part and at 100° C. (212° F.) in 0.3 part of water (U. S.). The concentrated, but not the largely diluted, aqueous solution yields a white precipitate with ammonium carbonate, On the addition of a few drops of chlorine water bromine is liberated, which dissolves in carbon disulphide with a brown-yellow or yellowish-brown color without a violet tint (absence of and difference from iodide).

Tests.—If 0.5 Cc. of sodium cobaltic nitrite test-solution be added to 5 Cc. of an aqueous solution of the salt (1 in 20), no precipitate or turbidity should occur within 10 minutes (limit of potassium). If to 0.4 Gm. of the salt in a 50 Cc. flask an excess of hydrochloric acid be added, and the mixture evaporated nearly to dryness on a water-bath, and if 10 Cc. of amyl alcohol (boiling-point 132° C.) be added and the mixture cautiously heated until the lower aqueous layer has evaporated, which may be facilitated by passing a current of air through the hot solution, then, after the addition of 3

drops of hydrochloric acid and boiling for 3 minutes, the resulting insoluble residue should weigh not more than 0.007 Gm. (limit of other alkalies). This test and separation depends upon the fact that lithium chloride is soluble in amyl alcohol while the chlorides of the other alkali metals are not. The addition of a slight excess of ammonia water to the previously acidified aqueous solution of the salt (1 in 20) should produce neither a turbidity nor a precipitate, either before or after boiling (absence of iron, aluminum, etc.). An aqueous solution of the salt (1 in 20), acidified with hydrochloric acid, should give neither a color nor a turbidity when mixed with an equal volume of hydrogen sulphide solution and kept corked at 35° C. (95° F.) for at least half an hour, either before or after adding ammonia water to slight alkalinity (absence of heavy metals). If 1 Gm. of the dry salt be dissolved in water to the volume of 100 Cc., then 20 Cc. of the solution, with 2 drops of potassium chromate test-solution, should require not less than 23.2 Cc. nor more than 24.4 Cc. of tenth-normal silver nitrate solution to produce a permanent red color.—U. S. Since 1 Cc. of the silver solution corresponds to 0.008634 Gm. of pure dry lithium bromide, 0.2 Gm. of such a salt would require 23.16 Cc. of the silver solution for precipitation, which practically coincides with the lower pharmacopœial figure, 23.2 Cc., the slight excess of the latter being required to give color to the indicator. But the pharmacopœial figure does not allow for the permissible limit of "other alkalies" present in the lithium bromide, which in the form of bromides would cause the titration figure to fall below the theoretical figure for a pure salt. It is possible for the salt to be contaminated with chloride, which would tend to throw the titration figure above the theoretical one, and chloride and "other alkalies" may be present in such proportion as to counteract each other and cause the titration to yield a figure identical with that for a pure salt. If the lithium bromide as found on the market always contains some chloride, then the pharmacopœial figure, 23.2 Cc., corresponding to a pure salt, is compatible with the permissible "other alkalies." The higher figure of the official assay, 24.4 Cc. of silver solution, limits the amount of chloride in the lithium bromide.

Action and Uses.—The employment of lithium bromide is practically the same as that of POTASSIUM BROMIDE (which see). It is thought by S. Weir Mitchell to be more hypnotic than the other bromides, but there is no experimental evidence to justify this claim. The dose is from 10 to 30 grains (0.6–2 Gm.), in solution.

LITHII CARBONAS, *U. S., Br.*—Lithium Carbonate.

Lithium carbonicum, P. G.; *Carbonate of lithia*, E.; *Carbonate de lithine, Carbonate lithique*, Fr.; *Lithiumkarbonat, Kohlensaures Lithium*, G.

Formula, Li_2CO_3. Molecular weight, 73.51.

Lithium carbonate should contain not less than 98.5 per cent. of the pure salt.

Preparation.—Lithium carbonate is prepared by various processes from *lepidolite*, a silicate mineral containing lithium. One of these is as follows: The mineral is heated with sulphuric acid; the aqueous solution, containing impure lithium sulphate, may be freed from most of the sulphates of aluminum and the alkalies by crystallizing them as alum, or it is treated with lime to separate metallic oxides and earths, and then precipitated by barium chloride to remove sulphate, and by ammonium oxalate to remove calcium. After evaporating to dryness, lithium chloride is dissolved by a mixture of alcohol and ether, and thus freed from the chlorides of rubidium, cæsium, sodium, and potassium, with which metals it is associated in the lepidolite. The concentrated aqueous solution of lithium chloride, treated with ammonium carbonate, yields a precipitate of lithium carbonate, which is washed with alcohol; the filtrate from the precipitate on being evaporated to dryness and ignited yields as chloride the lithium which had remained in solution. Lithium carbonate can only be prepared on a large scale, and it is the source from which all other lithium compounds are obtained.

Properties.—Lithium carbonate is a light white amorphous powder or is in minute crystalline grains. It has the specific gravity 2.11, is permanent in the air, inodorous, has a mild alkaline taste and a distinct alkaline reaction, and imparts a carmine color to flame. It is insoluble in alcohol, but soluble in 140 parts of boiling water and in 75 parts at 25° C. (77° F.); much more soluble in water saturated with carbon dioxide (U. S.), 70 parts of cold water (Br.). The solution has an alkaline reaction, precipitates the salts of the heavy metals, and on boiling decomposes ammonium salts. On heating the salt to dull redness it melts to a transparent liquid, loses a portion of its

carbon dioxide, and congeals on cooling to pearly oxycarbonate, which is permanent in the air; the fused salt corrodes glass, silver, and platinum. It dissolves with effervescence in dilute hydrochloric acid, and the solution, evaporated to dryness, leaves a residue of lithium chloride, which is soluble in spirit of ether, and the neutral solution of which yields a white precipitate with sodium phosphate.

Tests.—If 1 Gm. of lithium carbonate be dissolved in 40 Cc. of diluted acetic acid, no insoluble residue should remain. If 1 part of the salt be added to 20 parts of water and just sufficient hydrochloric acid be added for solution, then boiled and cooled, separate portions of the solution should respond to the tests for iron, aluminum, and heavy metals given under LITHII BROMIDUM. 0.2 Gm. of the salt dissolved in a slight excess of hydrochloric acid, and further treated as described under LITHII BROMIDUM, should leave a residue of not more than 0.003 Gm. (limit of other alkalies). If 0.5 Gm. of the salt be dissolved in 20 Cc. of normal sulphuric acid, it should require not more than 6.6 Cc. of normal alkali to neutralize the excess of acid in the solution, using methyl-orange test-solution as indicator.—U. S.

In this titration, 1 Cc. of normal acid represents 0.036755 Gm. of pure lithium carbonate, hence 13.4 Cc. (20–6.6 Cc.) represents 0.4925 Gm., or 98.5 per cent. The Br. P. requires the same per cent., which is determined by converting the carbonate into sulphate and weighing after heating to redness.

Action and Uses.—Lithium carbonate was formerly employed with the idea that it combined with the uric acid in the body and formed soluble urates which were eliminated by the kidneys. It was supposed that its administration not only prevented the formation of uric acid deposits in the joints, kidneys, and bladder, but also caused their solution. It is now known that this salt has a greater affinity for the acid sodium phosphate in the blood than for uric acid, and that the large quantity of water ingested during its administration is largely responsible for the removal of the latter substance. Lithium carbonate taken internally does not dissolve gouty deposits in the tissues, but it may be employed for the purpose of rendering the urine alkaline. When given in conjunction with copious draughts of water, it is sometimes beneficial in the treatment of rheumatoid arthritis and diabetes due to a gouty diathesis. It is, moreover, thought by some to be a valuable remedy in gout and chronic rheumatism. The dose is from 5 to 15 grains (0.30–1 Gm.), 3 times daily.

LITHII CITRAS, *U. S.*, *Br.*—Lithium Citrate.

Lithiæ citras, Lithium citricum.—Citrate of lithia, E.; *Citrate de lithine,* Fr.; *Lithiumcitrat, Citronsaures Lithium,* G.

Formula, $Li_3C_6H_5O_7 + 4H_2O$. Molecular weight, 280.08.

Lithium citrate should be kept in well-stoppered bottles, and, when carefully dried, should contain not less than 98.5 per cent. of the pure salt.

Preparation.—No official method is given in the pharmacopœias. Lithium citrate can be prepared by adding lithium carbonate to a solution of citric acid until the latter is neutralized, and evaporating the liquid to dryness, gradually raising the temperature to 115° C. (239° F.). As shown by the equation, $2H_3C_6H_5O_7.H_2O + 3Li_2CO_3 = 2Li_3C_6H_5O_7 + 3CO_2 + 4H_2O$, 419 parts of citric acid requires 221.61 parts of lithium carbonate, the yield of citrate being equal to the weight of acid used.

This method gives the anhydrous salt which was official in the U. S. P., 1890. If the above-mentioned solution be concentrated and allowed to crystallize, the resulting salt will have the formula, $Li_3C_6H_5O_7 + 4H_2O$, and contain 25.5 per cent. of water of crystallization, one-fourth of which cannot be eliminated at the temperature of a boiling water-bath; this is the salt recognized in the Br. P. and the present U. S. P. (1900).

Both the anhydrous salt in powder-form and the crystallized occur in commerce. For dispensing in solution the salt may well be prepared extemporaneously, the proportion of citric acid to lithium carbonate being 1000 : 528.6 (or 10 : 5.3), with a yield of 1000 (or 10) parts; on triturating in a mortar with a small quantity of hot water the decomposition is readily effected. Hager recommends precipitation of the concentrated slightly acid solution with alcohol, when the normal salt, containing 2 molecules, or 14.63 per cent., of water, is precipitated.

Properties and Tests.—Lithium citrate is a white powder or colorless crystals, dissolves in 2 parts of water at 25° C. (77° F.), and in 1.5 parts of boiling water (U. S.),

and may be obtained crystallized from a concentrated solution on standing. It is almost insoluble in alcohol or ether, and deliquesces in moist air (U. S.).

Investigation has shown that the commercial lithium citrate offered in this country is by no means uniform in composition, varying from an anhydrous salt to one containing one or more molecules of water; moreover, according to L. F. Kebler, the anhydrous salt is more or less hygroscopic, but becomes non-hygroscopic after a certain amount of moisture has been absorbed.

The salt has a neutral reaction to test-paper, is inodorous, has a saline, somewhat cooling taste, is soluble in glycerin, and insoluble or nearly so in alcohol. When heated, it blackens, gives off inflammable gases of a pungent odor, and finally a white residue is left, which, if neutralized with hydrochloric acid, is soluble in alcohol, and the solution, ignited, burns with a carmine color. The salt is recognized as a citrate by mixing its aqueous solution with calcium chloride, filtering if necessary, and heating the clear liquid, when a precipitate of calcium citrate will be deposited.

If the residue obtained by igniting 0.2 Gm. of the salt at a red heat be treated with a slight excess of diluted hydrochloric acid, and the filtrate and washings be further treated as described under LITHII BROMIDUM, the insoluble residue obtained should weigh not more than 0.002 Gm. (limit of alkalies). The solution of the salt (1 in 20) acidulated with hydrochloric acid, should not be colored or rendered turbid by an equal volume of hydrogen sulphide solution, when kept corked for at least half an hour at 35° C. (95° F.), either before or after making slightly alkaline with ammonia water (absence of heavy metals). If 0.5 Gm. of the anhydrous salt be cautiously ignited in a porcelain crucible, and the residue when cold be moistened with a few drops each of nitric and sulphuric acids and again cautiously ignited, and this repeated until the residue becomes white and constant in weight, the lithium sulphate thus obtained should be not less than 0.387 Gm., nor more than 0.394 Gm., and after dissolving in 10 Cc. of boiling water and acidifying with hydrochloric acid, then adding ammonia water in excess, it should not give a turbidity or precipitate, either before or after boiling (absence of iron, aluminum, etc.).—U. S.

417.12 parts of pure anhydrous lithium citrate would yield 327.93 parts of lithium sulphate, or 0.5 Gm. would yield 0.39308 Gm. of sulphate; hence 0.387 Gm. of sulphate in the test above represents 98.45 per cent. of pure salt. A residue of sulphate greater than the theoretical would indicate presence of other alkalies or impurities. The Br. P. requires that when 2 Gm. of the crystallized salt are dried at 100° C. (212° F.), it should lose about 6.38 Gm., and at 115.5° C. (240° F.) an additional 0.13 Gm., and on incinerating to whiteness 0.77 Gm. residue should remain, corresponding to 98.5 per cent. of pure citrate. F. B. Power (1900) calls attention to the fact that constant weight cannot be obtained at 100° C. (212° F.), and that all the water is not expelled at 115.5° C. (240° F.), but that a temperature of 140° C. (284° F.) is necessary.

Action and Uses.—The employment of this salt is the same as that of LITHIUM CARBONATE (which see). It is given in doses of from 10 to 20 grains (0.60–1.3 Gm.), in solution.

LITHII CITRAS EFFERVESCENS, *U. S.*, *Br.*—Effervescent Lithium Citrate.

Limonade sèche au citrate de lithine, Fr.; *Brauselithiumcitrat*, G.

Preparation.—Lithium citrate, 50 Gm.; sodium bicarbonate, dried and powdered, 570 Gm.; tartaric acid, dried and powdered, 300 Gm.; citric acid, uneffloresced crystals, 195 Gm. Powder the citric acid and mix it intimately with the lithium citrate and tartaric acid, then thoroughly incorporate the sodium bicarbonate. Place the mixture on a plate of glass or in a suitable dish, in an oven heated between 93° and 104° C. (199.4° and 219.2° F.). When the mixture, by the aid of careful manipulation with a wooden spatula, has acquired a moist consistence, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Keep the product in well-stoppered bottles.—U. S.

To prepare 4 avoirdupois ounces of the effervescent salt, use 87½ grains of lithium citrate, 987½ grains of sodium bicarbonate, 525 grains of tartaric acid, and 341 grains of citric acid in uneffloresced crystals, and proceed as directed above.

The formula of the present Pharmacopœia differs materially from that of 1890, since lithium citrate is used in place of a corresponding quantity of lithium carbonate and citric acid, and all sugar is omitted. The amount of lithium salt in the finished product is also considerably less than formerly, being equal to about 5 instead of 13.2 per cent. As the sodium bicarbonate will lose part of its carbonic acid during the heating, the weight of the final product will be reduced to that extent, and therefore amount to about 1000 Gm. The quantity of citric and tartaric acids ordered are just sufficient to neutralize the prescribed amount of alkali, the liberated carbonic acid, when the salt is dissolved in water, rendering the taste agreeably acidulous. The following formula of the British Pharmacopœia is almost identical with the preceding: Take 58 parts of sodium bicarbonate, 31 parts of tartaric acid, 21 parts of citric acid, and 5 parts of lithium citrate. The lithium citrate and citric acid are mixed, the tartaric acid is then added, and finally the sodium bicarbonate, the whole being thoroughly triturated and dried at 93.3°–104.4° C. (200°–220° F.) to granular form. The granules are dried at a temperature not exceeding 54.4° C. (130° F.); weight of product about 100 parts.

Action and Uses.—This combination forms an agreeable method for the administration of lithium citrate. The dose is from 1 to 2 drachms (4–8 Gm.).

LITHII SALICYLAS, *U. S.*—Lithium Salicylate.

Lithium salicylicum, P. G.; *Salicylate de lithine*, Fr.; *Lithiumsalicylat*, G.

Formula, $LiC_7H_5O_3$. Molecular weight, 142.99.

Lithium salicylate should contain not less than 98.5 per cent. of the pure salt.

Preparation.—This salt may be prepared by warming on a water-bath at 60° C. (140° F.) a mixture of 10 parts of lithium carbonate, 38 parts of salicylic acid, and 70 parts of water. After reaction is over, the liquid should be slightly but distinctly acid; if not so, more acid should be added. The liquid is then filtered through an iron-free paper and evaporated at 60° C. (140° F.). The mass is finally thoroughly dried in a drying-oven. The above conditions must be observed if a colorless product is desired. Keep in well-stoppered bottles. The pure salt of weakly acid reaction is not affected by light.

Properties.—The salt may be obtained crystallized in needles, but is usually met with as a white powder, deliquescent on exposure to air, odorless or nearly so, having a sweetish taste and a faintly acid reaction; very soluble in water and alcohol. When heated, the salt is decomposed, emitting the odor of phenol, and finally leaves a black residue having an alkaline reaction, which imparts a crimson color to a non-luminous flame. On supersaturating the dilute aqueous solution with hydrochloric acid a bulky white precipitate of salicylic acid is obtained which is soluble in boiling water, from which it crystallizes on cooling; also soluble in ether, and producing an intense violet color with ferric salts. On adding to a small portion of the salt, in a test-tube, about 1 Cc. of concentrated sulphuric acid, and then, cautiously, about 1 Cc. of methyl alcohol in drops, on heating the mixture to boiling the odor of oil of gaultheria will be evolved.

Tests.—The aqueous solution should be colorless (absence of iron and organic coloring-matters) and not effervesce on the addition of an acid (absence of carbonate). If copper sulphate test-solution be added to an aqueous solution of the salt (1 in 20), the mixture should have a bright-green color. If an excess of hydrochloric acid be added to a concentrated aqueous solution of 0.7 Gm. of the salt, the precipitate, when thoroughly washed and dried on a filter, should conform to the reactions and tests given under ACIDUM SALICYLICUM; the filtrate and washings, if treated further as described under LITHII BENZOAS, should yield an insoluble residue weighing not more than 0.005 Gm. (limit of other alkalies). If 1 Gm. of the salt be dissolved in 20 Cc. of water, and the salicylic acid precipitated by a sufficient quantity of hydrochloric acid, the filtrate should respond to the tests for iron, aluminum, heavy metals, etc., given under LITHII BENZOAS. When assayed by the method given for the latter salt, 0.5 Gm. of dry lithium salicylate should yield not less than 0.188 Gm., nor more than 0.192 Gm., of lithium sulphate.—U. S.

285.98 parts of pure dry lithium salicylate would yield 109.31 parts of the sulphate,

or 0.5 Gm. would yield 0.19111 Gm. of the sulphate; hence 0.188 Gm. of sulphate in the assay represents 98.37 per cent. of pure salicylate.

Action and Uses.—The medicinal properties and untoward effects of lithium salicylate differ in no particular from those of sodium salicylate (see Sodii Salicylas), except that it is said not to irritate the stomach. The average daily dose is from 40 to 60 grains (2.6–4 Gm.), best administered in aqueous solution.

LITHIUM.—Lithium.

Lithium, Fr., G.

Symbol, Li. Atomic weight, 6.98. Univalent in nearly all of its compounds.

Lithium is a member of the family of elements known as the alkali metals. It occurs in nature very widely distributed, but in small quantities. As silicate it is found in the minerals petalite, triphane, lepidolite, spodumene, and tourmaline, as phosphate in triphyline and amblygonite. It is found in minute quantities in the ashes of some plants, as sea-tangle and tobacco, and in many mineral springs, often as carbonate; the waters of the Mur spring at Baden-Baden and of a hot spring at Wheel-Clifford, in Cornwall, are the richest known, the latter, according to W. A. Miller (1864), containing 26.05 grains of LiCl in the Imperial gallon. Lithium is said to occur in the mother-liquors of tartaric acid manufacture in sufficient quantity to justify extraction. Lithium was discovered by Arfvedson (1817) in petalite and other Swedish minerals, and by Berzelius (1822) in the mineral waters of Carlsbad, Marienbad, and Franzensbrunn. It is obtained from the minerals (usually lepidolite, which contains 3.6 per cent.) in the form of carbonate (see this), which is the mother-substance for preparing all other salts. The metal was first isolated by Bunsen and Matthiessen, 1855. It is now obtained by electrolysis of the molten chloride.

Lithium is silver-white, shining, much harder than potassium or sodium, but softer than lead. It melts at 186° C. (366.8° F.), but is not volatile at red heat, has the specific gravity 0.59, is the lightest of all metals, burns when heated in air or in oxygen to lithium oxide, Li_2O, and like sodium decomposes water at the ordinary temperature, forming hydrogen and lithium hydroxide. It has a remarkable affinity for nitrogen, combining with it slowly in the cold; but when heated, it burns in nitrogen energetically, forming lithium nitride, Li_3N.

Contrary to the other alkali metals, lithium forms an infusible, stony, white oxide, Li_2O, which dissolves in water only slowly. Lithium hydroxide, LiOH, is less hygroscopic and less soluble in water than sodium hydroxide and sparingly soluble in alcohol.

Lithium nitrate, $LiNO_3$, is much more deliquescent than sodium nitrate. **Lithium sulphate** forms glistening prisms, $Li_2SO_4.H_2O$, soluble in 3 parts of ice-water and in 3.5 parts of hot water. Lithium salts are as a rule freely soluble in water, but the carbonate and phosphate are striking exceptions, and in this respect lithium shows a marked contrast to the other alkali metals and exhibits an approach to the alkaline earth metals. The carbonate is official and has been described. The **phosphate,** $Li_3PO_4 + \frac{1}{2}H_2O$, formed by addition of disodium phosphate to a lithium salt in solution, is a heavy, white, granular powder, which loses its crystal-water at 100° C. and requires 2540 parts of pure water, or 3920 parts of ammoniacal water for solution. **Lithium fluoride,** like calcium fluoride, is insoluble in water. **Lithium chloride,** LiCl, crystallizes in cubes, is easily fusible, salty, and deliquescent. It forms crystalline compounds with alcohol and many other organic bodies, and absorbs ammonia gas with great energy; in these respects it behaves remarkably much like calcium chloride. If a mixture of the chlorides of lithium, sodium, and potassium is treated with alcohol, only the lithium chloride is dissolved, and thus can be separated from the other chlorides. Besides the official salts, various other salts of lithium have been put on the market as remedies for various ills. Some of these are the following: Lithium bitartrate (tartarlithin), L. formate, L. glycerophosphate, L. hippurate, L. iodate, L. sulphoichthyolate, and L. theobromine-salicylate (uropherin). For details in reference to the last-named compound, see under Sodii Salicylas.

LOBELIA, *U. S., Br.*—Lobelia.

Herba lobelia, P. G., P. A.—*Indian or Wild tobacco, Asthma-weed, Puke-weed, Bladder pod*, E.; *Lobelienkraut*, G.; *Lobélie enflée*, Fr.; *Tobaco Indiano*, Port.

The dried leaves and tops of *Lobelia inflata* L. (Fam. *Campanulaceæ*), collected after a portion of the capsules have become inflated.

Lobelia is official in all pharmacopœias, though they differ considerably in the wording, and to some extent in the meaning of their definitions. The British says merely "The dried flowering herb"; the German, "The dried upper portion of the flowering plant." The drug is probably somewhat more active in the state required by the U. S. P., since it then bears some seeds.

Fig. 260.

Lobelia (¾ Nat.).

Origin.—The plant is an annual herb, growing usually in open, somewhat grassy and rather dry locations throughout eastern and central North America. Flowering commences in early to middle

Fig. 261.

Lobelia-seed, magnified.

Fig. 262.

Flower, and section through stamens and pistil (× 5).

summer and continues till fall, the plant branching continuously until destroyed by cold weather. Although growing abundantly in pastures, it is not eaten by grazing animals.

Description.—More or less, usually sparsely, clothed on the stems and leaves, especially on the veins of the lower leaf-surfaces, with stout, spreading, white hairs; stems coarsely angled, often purplish; leaves alternate, exstipulate, sessile or very shortly petioled, rarely exceeding 5 Cm. (2 In.) long and about half as broad, ovate or oval, usually obtusish, irregularly and shortly serrate-dentate, the teeth usually with whitish tips; mostly pale- or yellowish-green; racemes terminating the branches, elongated, loosely flowered; flowers bracted, short-pedicelled, about 6 to 8 Mm. (¼ to ⅓ In.) long, the calyx-tube adherent, ovoid, and shorter than the 5 slender teeth, becoming much larger, globular, and inflated after flowering; corolla blue, tubular, with the tube cleft along the upper side, 2-lipped and irregular, the 5 stamens having both filaments and anthers coherent; capsule inflated, 2-celled, containing numerous seeds; odor narcotic, irritating; taste becoming burning and acrid.

The drug is not adulterated, but often contains an undue amount of the stemmy portion, or even the root.

Constituents.—Lobelia contains gum, resin, fixed oil, the alkaloid *lobeline* combined with *lobelic acid*, *lobelacrin*, *inflatin*, and *lobelianin*, a pungent, odorous volatile oil with but little taste. The seeds contain the most lobeline, and 30 per cent. of a nearly odorless, bland, drying, fixed oil. *Lobeline* ($C_{18}H_{23}O_3$?) has been always considered a yellowish oily liquid, lighter than water, of somewhat aromatic odor and persistent acrid taste, and forming crystalline salts with mineral acids. But Lloyd (1886) claims to have separated from this the pure lobeline as a colorless, odorless, amorphous, non-hygroscopic body, soluble in alcohol, ether, chloroform, benzene, and carbon disulphide, slightly soluble in water, easily decomposable by heat, and not forming crystallizable salts. *Lobelacrin* forms brown warty tufts soluble in ether and chloroform, and only slightly in water. Boiled with dilute acids or alkalies it splits into sugar and lobelic acid. *Inflatin* is a colorless, tasteless, odorless, neutral principle, insoluble in water or glycerin, but soluble in chloroform, ether, benzol, and carbon disulphide, and slightly in alcohol.

Pharmaceutical Preparations.—Ethereal Tincture of Lobelia, N. F.; Fluid-extract of Lobelia, Tincture of Lobelia, U. S. P.; Vinegar of Lobelia, N. F.

Action and Uses.—Overdoses of lobelia produce violent nausea and vomiting, muscular relaxation, intense prostration, respiratory and circulatory depression, a cold, clammy skin, and subnormal temperature. If the dose is sufficiently large, collapse with coma and occasionally convulsions precede death. The drug depresses the motor nerve-trunks, the peripheral vagi, and the respiratory centre. The heart and peripheral circulation are at first depressed, but secondarily blood-pressure is increased because of the asphyxia which it produces. Cases of poisoning should be treated by the application of external heat, the administration of rapidly acting diffusible stimulants, such as ammonia, to support the circulation, and the employment of opium to relieve pain and vomiting. Lobelia may be employed in the treatment of spasmodic asthma, unless due to cardiac disease, when its administration is contraindicated. It has also been employed for croup, catarrh, whooping-cough, and chronic bronchial affections, but has never been highly esteemed in these conditions. Given in small doses it is thought to be valuable in the treatment of atonic constipation when the feces are hard and dry.

As an expectorant the dose is from 10 to 20 minims (0.6–1.3 Cc.) of the tincture. As an emetic it may be given in doses of from 1 to 2 fluidrachms (4–8 Cc.). Vinegar of lobelia, a 10 per cent. preparation made by maceration with dilute acetic acid, may be employed in the same doses.

Allied Products.—The genus *Lobelia*, L., comprises some 200 species, distributed through temperate and tropical regions of almost the entire world. Almost wherever found they are in bad repute for their poisonous properties. Some 20 species are recorded as being medicinally employed or of importance as poisons. *L. nicotianifolia* Heyne (*Dhvala, Adavi-pokaku, Bokenul*, etc.), of India, is employed like *L. inflata*, as is *L. Delisseana* Gaud., of the Sandwich Islands.

L. cardinalis L., the *Cardinal flower* or *Scarlet lobelia* of the eastern United States, is somewhat used as an anthelmintic. *L. syphilitica* L., the *Great lobelia* or *Blue cardinal flower*, abundant in swampy grounds of eastern and central North America, is an old-time remedy for syphilis, and its seeds are employed like those of *L. inflata*. It is a rather stout, very leafy perennial, 1 to 3 feet high, slightly hairy upon the stem. The leaves are 5 to 15 Cm. (2 to 6 In.) long, and about a third as wide, oblong-ovate, narrowed at both ends, and mostly acute at the apex, coarsely and irregularly crenate-dentate, the lower tapering into a petiole. The flowers are short-pedicelled, racemose, varying from bright blue to nearly white, about an inch in length. In the size of the blue flowers it differs from all other east-American species. *L. pinifolia* L., of southern Africa, is used as a diuretic and antirheumatic. Other species noted for their poisonous properties are *L. splendens* Willd. and *L. fulgens* Willd., both of Mexico; *L. urens* L., and *L. Dortmanni* L., of Europe, the latter also in the United States; *L. cirsiifolia* Lam. (*Tupa c.* DC.), *L. stricta* Swz. (*Tupa s.* DC.), and *L. coccinea* Stockes, of tropical America; *L. purpurascens R.* Br., of Australia; *L. decurrens* Cav., of Peru; *L. laxiflora angustifolia* DC. (*Xochipipile*), of Mexico, and especially *L. Tupa* L. (*Tupa Feuillei* Don.), of tropical America.

Isotoma longiflora (L.) Presl. (*Lobelia l.* L.; *Hippobroma l.* Don), of tropical America, is regarded as one of the most violently poisonous of known plants. Its action is much like that of official Lobelia. It is used externally as an epispastic and internally as an anti-syphilitic.

Tupa Berterii DC. (*Lobelia serrata* Meyer), of Chile, acts much the same, and is used as a fish poison. The large Andean genus *Siphocampylos*, many of its species of great beauty, possesses many poisonous species. Several species of this genus are said to yield rubber.

LORANTHACEÆ.—The Mistletoe Family.

A small family of about 500 species of plants of very curious habits and peculiar appearance, being true parasites, for the most part upon trees, the bark and wood of which are penetrated by absorbing organs which take the place of roots. For the purpose of better attaching themselves to the bark in falling, the seeds and fruits are often enclosed in exceedingly viscid substances, and the latter have been considerably used in the manufacture of bird-lime. Owing to the peculiar parasitical habits of the plants, well illustrated by the common mistletoe (*Viscum album* L.; *Mistel, Eichenmistel*, G.; *Gui de chêne, Gillon*, Fr.; *Visco, Muerdago*, Sp.), they have always been objects of superstition and occasions for religious fanaticism. Most of their medicinal use has probably no better basis, although many species apparently possess some power as uterine stimulants.

Viscum or Mistletoe (see above).—This species is indigenous to Europe, and is chiefly found upon apple, pear, plum, and similar trees, but grows upon others as well. The plant constitutes a well-known Christmas decoration. The stems are greenish and brittle, the

leaves opposite, estipulate, lanceolate to spatulate, obtuse and entire; the flowers obscure and monœcious or dicœcious, sessile in small clusters or short spikes; the fruit a small, whitish, 1-seeded berry. The odor is rather weak, but heavy and unpleasant, and the taste sweetish, bitter, somewhat astringent and mucilaginous. The constituents are mucilage, sugar, resin, volatile and fixed oil, and a little tannin, together with the peculiar glutinous substance *viscin*, soluble in ether and oil of turpentine, insoluble in water, alcohol, and fixed oils. In the living plant it appears to be in very slight amount, but apparently forms under the action of some enzyme. Viscum appears to be very uncertain in its effects. It has been employed as a powerful nervine in the treatment of hysteria, chorea, and epilepsy, but is probably of little value in these conditions. Cases are on record in which the ingestion of large quantities of the berries of American mistletoe have produced grave symptoms, and even death, the most prominent symptoms being great thirst, vomiting, purging, and collapse. American mistletoe has been recommended as an oxytocic, but is considered quite uncertain in its action. The drug has been employed during labor and in the treatment of post-partum hemorrhage. The dose of either variety is from ½ to 1 fluidrachm (2–4 Cc.) of a fluidextract made from the leaves and stems.

American mistletoe or *Golden bough* is the somewhat similar stems and herbage of *Phoradendron flavescens* (Pursh) Nutt. (*Viscum f.* Pursh), native of the southern United States. It is a somewhat stouter plant, occasionally slightly pubescent, the leaves oblong to obovate, 1.5 to 3 Cm. (⅗ to a little more than 1 In.) long, entire, rounded at the summit, 3- to 5-nerved, and of a yellowish-green color. The constituents, so far as known, are identical with those of the European. It is somewhat employed for the same purposes.

Loranthus Europœus Jacq. is used similarly to the European Mistletoe, as are many species of *Phoradendron*, *Loranthus*, and related genera of the tropics of both the Old and New Worlds.

LOTIO HYDRARGYRI FLAVA, *Br.*—Yellow Mercurial Lotion.

Lotio flava, N. F.; *Aqua phagedœnica flava.—Yellow Wash, Yellow Lotion*, E.; *Eau phagédénique, Eau divine de Fernel*, Fr.; *Phagedänisches Wasser, Altschadenwasser*, G.

Preparation.—Take of mercuric chloride, 20 grains; solution of lime, 10 fluidounces. Mix.—Br.

Take of corrosive chloride of mercury, 3 Gm.; boiling water, solution of lime, of each a sufficient quantity to make 1000 Cc. Dissolve the corrosive chloride of mercury in 35 Cc. of boiling water, and add the solution to a sufficient quantity of solution of lime to make 1000 Cc.—N. F.

A double decomposition takes place, resulting in the formation of calcium chloride and finely divided yellow mercuric oxide. The mixture should be well agitated whenever any of it is to be dispensed.

Action and Uses.—Yellow wash is somewhat stimulating and may be used with advantage in the treatment of sluggish venereal sores.

LOTIO HYDRARGYRI NIGRA, *Br.*—Black Mercurial Lotion.

Lotio nigra, N. F.; *Aqua phagedœnica nigra.—Aqua nigra, Aqua mercurialis nigra, Black Lotion, Black Wash*, E.; *Eau phagédénique noir*, Fr.; *Schwarzes Wasser*, G.

Preparation.—Take of mercurous chloride, 30 grains; glycerin, ½ fluidounce; mucilage of tragacanth, 1¼ fluidounces; solution of lime, a sufficient quantity. Triturate the mercurous chloride with the glycerin and mucilage of tragacanth; transfer to a bottle; add 2 fluidounces of the solution of lime; shake well; add sufficient solution of lime to produce 10 fluidounces.—Br.

Take of mild chloride of mercury, 7.5 Gm.; water, solution of lime, of each a sufficient quantity to make 1000 Cc. Triturate the mild chloride of mercury with 35 Cc. of water, and gradually add a sufficient quantity of solution of lime to make 1000 Cc.—N. F.

The chemical reaction between the mercurial salt and solution of lime results in producing calcium chloride and black mercurous oxide. The presence of glycerin and tragacanth mucilage in the British preparation serves to keep the oxide in better suspension. The mixture should be well agitated whenever any of it is to be dispensed.

Action and Uses.—Black wash is employed locally as a mild sedative astringent in the treatment of venereal sores.

LUPULINUM, *U. S., Br.*—Lupulin.

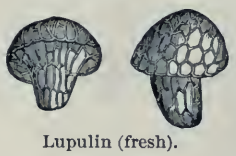
Glandulæ lupuli, P. G.—*Lupuline*, Fr. Cod.; *Lupulite*, E.; *Hopfenmehl, Lupulin*, G.; *Lupulina*, Sp.; *Luppolina*, It.

The glandular trichomes separated from the fruit of *Humulus Lupulus* L. (Fam. *Moraceæ*).

Lupulin is official in nearly all pharmacopœias, which variously specify the following requirements: It burns in a flame like Lycopodium; becomes plastic when triturated in a mortar with strong pressure; not more than 40 per cent. is insoluble in ether; it should be renewed annually, being rejected when dark-brown or cheesy-smelling; should be kept protected from light. The ash allowance in different pharmacopœias ranges from 10 to 20 per cent. Lupulin is said to have ignited spontaneously.

Origin and Description. (For an account of its origin and for botanical synonyms, see HUMULUS.)—On handling dry hops, the glandular powder becomes detached, and is freed from fragments of the bracts, etc., by sifting; about 10 per cent. of the weight of the hops can be obtained.

FIG. 263.



Lupulin (fresh).

A bright, light brownish-yellow (becoming yellowish-brown) mobile, granular resinous powder, having a strong odor of hops and a strongly aromatic and bitter taste; of low specific gravity, floating lightly on water. Under the microscope it is seen to consist of two hemispheres, the lower and firmer of which is somewhat obtusely conical or top-shaped, the upper one rounded, the surface of both reticulate. In the dry state the lower one nearly retains its shape, but the more delicate upper part collapses and forms a flattish hood. The glands contain a brown-yellow liquid which dries to a resinous mass. Not less than 60 per cent. of lupulin is soluble in ether. Lupulin should be free from sand, which readily subsides from it when agitated with water, and, on incineration, should yield not more than 10 per cent. of ash.

A granular powder of this sort is peculiarly amenable to adulteration, and this has been largely practised. The substances employed are chiefly sand and other earthy matter, which increase the ash percentage. Starch and all powdered vegetable tissue are very readily detected by microscopical examination.

Constituents.—The composition of lupulin is similar to that of hops, but it contains no alkaloid. Lupulin yields a tasteless resin, myricin (myricylic palmitate), and bitter *lupamaric* or *hop-bitter acid*. This forms white crystals, which on exposure to air turn yellow. They are soluble in water, and, boiled with dilute sulphuric acid, yield crystalline lupulic acid, and lupuliretin. On distilling with water, the glands yield valerianic acid and a volatile oil.

Pharmaceutical Preparations.—FLUIDEXTRACT OF LUPULIN, OLEORESIN OF LUPULIN, U. S. P.

Action and Uses.—Lupulin, like HUMULUS (which see), is employed as an antispasmodic and nervous sedative in the treatment of hysteria, insomnia, and nervousness. It may be given in doses of from 2 to 5 grains (0.12–0.30 Gm.), which amount may be increased if needed.

LYCOPODIUM, *U. S., P. G.*—Lycopodium.

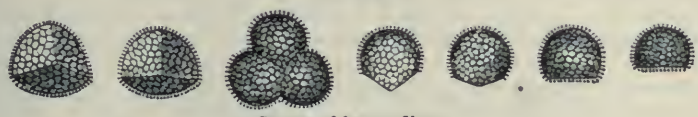
Semen lycopodii, Pulvis lycopodii, Sulphur vegetabile.—*Vegetable sulphur*, E.; *Bärlappsamen, Streupulver, Hexenmehl, Blitzpulver*, G.; *Lycopode, Soufre végétal*, Fr.; *Licopodia*, Sp.

The spores of *Lycopodium clavatum* L. and of other species of *Lycopodium* (Fam. *Lycopodiaceæ*).

Origin.—The common *Club-mosses* are prostrate and creeping evergreen perennials, found in dry woods over most of the globe, but especially in northern countries. The powder is mostly collected in central Europe. The spores are contained in sporangia borne in the axils of bracts which form dense, erect, long-peduncled spikes, 1 to 4 inches in length. The spikes are collected entire, just before maturity, and after drying, during which the spores ripen, the latter are shaken and sifted out.

Description.—A fine, very mobile, pale-yellow, odorless and tasteless powder, floating upon water, and wetted by it with difficulty, and only after continued trituration, unless the surface of the spores has been cleansed of the oily coating contained in the subepidermal or endosporial layer, by washing with alcohol, ether, or chloroform. After boiling, it sinks in water. Trituration imparts a darker tint and renders it more coherent and greasy. Slowly heated, it burns quietly, but thrown into a flame, the spores explode with a hissing noise. The spores are about 25 mikrons in diameter, and exhibit a short, 3-sided pyramid, the fourth side being nearly hemispherical, the surface reticulate with 5- or 6-sided meshes, and the edges beset with projecting points. There is no blue coloration with iodine. The ash should not exceed 5 per cent.

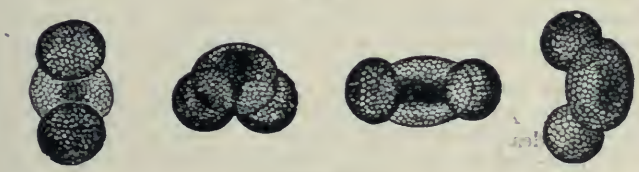
FIG. 264.



Spores of lycopodium.

Constituents.—Lycopodium yields about 50 per cent. of a neutral, odorless, non-drying oil, similar to expressed oil of almonds. This is composed of 3 to 8.2 per cent. of glycerin, 0.3 of phytosterin, 2 of lycopodic acid, 80 of oleic acid, and 3 of arabic, palmitic, stearic, and myristic acids (Langer says also *decyliso-propylacrylic* acid). The ash is under 4 per cent. Lycopodic acid ($C_{18}H_{36}O_4$) crystallizes in fine silky needles.

FIG. 265.



Pollen of pine.

Adulteration.—Lycopodium is subjected to extensive adulteration. 25 per cent. of starch has been reported as detected by sinking in carbon bisulphide and being colored blue by iodine. Pine pollen has been used largely, and is seen to be always in 3's, forming a large plano-convex body with a globular one attached to either end of the flat side. Mineral substitutes sink in carbon bisulphide and increase the yield of ash. Dextrin is dissolved by water, rosin by alcohol. All these substitutes are readily distinguished from the spores by microscopical examination.

Action and Uses.—Lycopodium is practically never administered internally. At one time a decoction of the moss was employed in rheumatic, pulmonary, and renal complaints, but it has fallen into disuse. The spores are employed in medicine only as a dusting-powder, and may be used with advantage in the prevention of excoriations, especially about the genitals of infants.

Allied Products.—The genus Lycopodium contains more than 100 species, the herbage of several being employed in domestic medicine. Thus, *L. Selago* L. (*Kolbenmoos, Purgierbärlapp*), of Europe, is used to poison animals and as a drastic and emmenagogue. Similar properties are attributed to *L. Saururus* Lam., of the Argentine, from which the alkaloid *piliganine* was extracted, 2 grains killing a dog, and $\frac{1}{6}$ to $\frac{1}{3}$ grain of the hydrochloride being purgative, as are 6 grains of the alcoholic extract of the plant. Larger doses are emetic. *L. polytrichoides* Kaufl., of the Sandwich Islands, and *L. cernuum* L., of the tropics, act similarly, and in Venezuela *L. rubrum* Cham. is used in elephantiasis. The alkaloid *lycopodine* is reported in *L. complanatum* L.

Small doses of the poisonous species are used as tonics.

Equisetum.—Closely related to the *Lycopodiaceæ* is the family *Equisetaceæ*, or Scouring Rush Family, several species of which have been used medicinally to a slight extent, though without important constituents or, apparently, definite physiological properties. *Equisetum* or *Horse tail* (*Pferdeschwanz, Schachtelhalm, Zinnkraut, Scheurkraut*, G.; *Prêle*, Fr.; *Coda di cavallo*, It.; *Cola de caballo*, Sp.), as commonly understood, is the perennial herb *Equisetum arvense* L., also known as *Cat's tail*, and which grows almost throughout the central portion of the north-temperate zone, mostly in sandy, though somewhat damp soil. It propagates by slender tuberiferous rhizomes, and produces fertile and sterile shoots, which do not at

all resemble one another and are destitute of true leaves. The fertile shoots are brownish, simple, erect, a few inches high, thick and somewhat succulent, ribbed, scale-bearing at the nodes, and each terminating in an ovoid spike which bears the abundant green spores on the under side of horizontal lamellæ. The sterile shoots, which are alone employed in medicine, appear a little later, are a foot or two long, more slender than the fertile, green, furrowed, slenderly and widely branched, the branches somewhat quadrangular and bearing 4 scales at each node. They are slightly harsh to the touch, owing to their siliceous covering. The herb contains a peculiar acid which has been called *equisetic acid*, but is claimed to be identical with aconitic acid. There is yielded 4 or 5 per cent. of ash, nearly half of it silica. The drug has been used indefinitely, chiefly in domestic practice.

E. hiemale L., the *Scouring* or *Polishing rush* or *Dutch rush*, *Shave grass*, *Horse pops* or *Rough horse-tail* (*Tischlers* or *Polir Schachtelhalm*, G.), having the same range, is much taller (up to 3 feet), darker, with about 20 narrow scales at each joint, black-girdled at their bases and summits, and much rougher than the former, on which account it has been largely used for polishing. It yields two or three times as much ash, most of it silica, together with a little resin, sugar, and various salts. This species is used in China, in ophthalmic practice, under the name *Muh-ts'ih*. In South America, *E. Bogotense* Kunth and *E. giganteum* Thunb. (*E. ramosissimum* Desf.; *E. elongatum* Willd.) are used as intestinal and urethral astringents. It is claimed that *E. palustre* L. and *E. limosum* contain alkaloidal substances which are poisonous to animals, and *E. arvense* is numbered among the suspicious stock-poisoning plants of the northwestern United States.

LYTHRACEÆ.—The Loosestrife Family.

A small family of some 400 or 500 species, most abundant in warm countries, and of little economic importance except for its ornamental properties. Many of the species contain bitter, acrid, and irritant principles which appear worthy of investigation.

Henna or *Alhenna* (also called *Alkhanna* or *Alcanna*) is a yellow or orange coloring-matter obtained from the leaves of *Lawsonia inermis* L. (*L. alba* Lam.; *L. spinosa* L.), the *Henna plant*, *Egyptian privet*, or *Jamaica mignonette*, a fragrant white flowered shrub of southern Asia and adjacent regions. Although somewhat used as an astringent and in the treatment of jaundice, which latter idea probably depends upon the yellow color, it is chiefly employed for staining the hair, finger-nails, etc. The astringent principle has been named *henotannic acid*.

Ammania.—This genus of about 30 species of annual herbs, besides being somewhat aromatic, is noted for the acrid and counterirritant properties of its herbage. A number of species (*A. Indica* Lam., *A. vesicatoria* Roxb., etc.) are employed in the East Indies for blistering purposes, the fresh leaves being used and producing a blister in about half an hour.

Lythrum or *Loosestrife* (*Purple* or *Milk willow-herb*, *Willow-weed* or *Willowwort*, *Purple loosestrife*, *Purple grass* or *Long purples*, *Sage willow*, *Red Sally* or *Rainbow weed*, E.; *Rotherweiderich*, G.; *Salicaire*, Fr.) is the *Herba salicariæ*, derived from *L. Salicaria* L. (*Salicaria vulgaris* Moench), a tall downy perennial herb of Europe and Asia, abundantly naturalized in the northeastern United States, where it flowers from midsummer to early fall. The leaves are opposite or whorled in 3's, about 75 Mm. (3 In.) long, lanceolate, sessile, clasping by the heart-shaped base. The flowers are apparently whorled, form a long, interrupted, wand-like spike, and have 6 showy purple or sometimes whitish petals and 12 stamens. The herb has a mucilaginous, mildly astringent taste. The blackish-brown, branching, and fibrous root is astringent. The principal constituents of Loosestrife are mucilage and tannin. Several species of this genus are used in Mexico under the name *Yerba del cancer*. Similarly employed in tropical America, in the ignorant treatment of supposed syphilitic disorders, are various species of the related genus *Parsonsia*, P. Br. (*Cuphea*). In Mexico the purgative and diuretic herbage and juice of *Heimia salicifolia* (H. B. K.) Link et Otto (*Nesæa s.* H. B. K.), containing the amaroid *nessin*, is used under the name *Hanchinol* or *Abrosol*, as also is *H. syphilitica* DC. (*Nesæa s.* Steud.). Lythrum possesses astringent and demulcent properties. A decoction (1 ounce [Gm. 30] to a pint [Cc. 480]), has been recommended in the treatment of dysentery, chronic diarrhœa, leucorrhœa, and passive uterine *hemorrhage*.

M.

MAGNESII CARBONAS, *U. S., Br.*—Magnesium Carbonate.

Magnesium carbonicum, P. G.; *Magnesiæ carbonas, Magnesia alba.—Carbonate of magnesia*, E.; *Carbonate de magnésie, Magnésie blanche*, Fr.; *Magnesiumkarbonat, Weisse Magnesia*, G.; *Carbonato di magnesia*, It.; *Carbonato de magnesia*, Sp.

Formula approximately, $(MgCO_3)_4.Mg(OH)_2.5H_2O$ (U. S.). $(MgCO_3)_3.Mg(OH)_2.4H_2O$ (Br.). Molecular weight, 482.26 (U. S.).

It should yield, upon ignition, not less than 40 per cent. of residue, of which not less than 96 per cent. should consist of pure magnesium oxide.—U. S.

Preparation.—Only one form of the carbonate is official in the U. S. P., *light magnesium carbonate*, but no process for preparing it is given. The Br. P. gives processes for preparing, and recognizes two forms, namely, *Magnesii Carbonas Levis* or *light magnesium carbonate*, and *Magnesii Carbonas Ponderosus* or *heavy magnesium carbonate*.

The British formula for the light magnesium carbonate consists in dissolving 10 parts of magnesium sulphate, 12 parts of crystallized sodium carbonate, each in 80 parts of cold water, mixing the two solutions and boiling the mixture for 15 minutes, filtering and washing with boiling water until the filtrate gives no precipitate with barium chloride. The product is dried at 100° C. (212° F.).

The process for the heavy carbonate differs from the above in the fact that one-fourth as much water is used for solution of the salts, and the mixture is evaporated to dryness, the residue digested for half an hour with 40 parts of water, filtered, washed, and dried as above.

It is improbable that the two forms of the carbonate have the same composition, as given in the Br. P., and, moreover, the same criticism holds as in the case of bismuth subcarbonate in regard to assigning a definite formula, which varies with conditions, depending upon the concentration of the solutions employed, and the temperature at which the decomposition is effected and the precipitate dried. Pure normal magnesium carbonate is never obtained when a solution of the sulphate or chloride is mixed with an alkali carbonate, but always a basic carbonate, the proportion of normal carbonate present in the precipitate being greatest when dilute solutions are used at ordinary temperature.

If solutions of magnesium sulphate and sodium carbonate be mixed in the cold, no carbon dioxide is eliminated, a voluminous precipitate of basic magnesium carbonate being thrown down, while an acid magnesium carbonate, $MgH_2(CO_3)_2$, remains in solution; but if the solution be mixed warm or hot, carbon dioxide is evolved. The reaction producing the official magnesium carbonate of the U. S. P. is probably as follows: $5(MgSO_4 + 7H_2O) + 5(Na_2CO_3 + 10H_2O) = (MgCO_3)_4.Mg(OH)_2.5H_2O + 5Na_2SO_4 + CO_2 + 79H_2O$; dilute solutions being used and mixed at a temperature not above 55° C. (131° F.); the precipitate is washed to remove sodium sulphate and dried without heat. Potassium carbonate is not so good as sodium carbonate in the preparation of magnesium carbonate, as it is not so pure, and the potassium sulphate formed is more difficult to wash out, in consequence of which the precipitate is apt to be gritty and to have a slightly saline taste.

Magnesium carbonate may be obtained from the mother-liquors or bittern of saltworks, but it is then contaminated with calcium carbonate. It is made in large quantities in England, Germany, and this country by Pattinson's method from *dolomite*, a native magnesium limestone, by ignition and treatment with water and carbon dioxide under pressure; acid magnesium carbonate is formed and readily dissolved, and the solution, separated from the calcium carbonate, is treated with steam, whereby the basic carbonate is precipitated.

Light magnesium carbonate is often prescribed as *Magnesia alba*. In German-speaking countries the term magnesia is understood to refer to the light carbonate, while in English-speaking countries it refers to the oxide or calcined magnesia.

Properties.—The heavy and light magnesium carbonates differ chiefly in the degree of aggregation of their molecules, the former being slightly granular, the latter a smooth

and less dense powder, both being inodorous, and of a slight earthy taste. They are almost insoluble in water, requiring, according to Fyfe, 2500 parts of cold and 9000 parts of boiling water for solution, and when it is moistened with water and applied to turmeric paper a brown color is gradually produced. When heated to dull redness water and carbon dioxide are given off, and magnesia remains. They dissolve with copious effervescence in dilute sulphuric, hydrochloric, and other acids, and the solutions have the chemical behavior of magnesium salts.

Tests.—Magnesium carbonate may be contaminated with calcium compounds, and from incomplete washing also with the acidulous radicals contained in the mother-liquor, more particularly with chlorides, bromides, and sulphates. These impurities are detected by dissolving the carbonate in dilute nitric acid, and this solution should not be precipitated by silver nitrate (chloride and bromide) or barium nitrate (sulphate); neutralized with ammonia, it should not be precipitated by ammonium oxalate (calcium). On the addition of ammonia or ammonium carbonate a white precipitate is produced, which should be completely soluble in an excess of the precipitant and in ammonium chloride (an insoluble portion would indicate alumina), and the ammoniacal solution should not yield a white precipitate with hydrogen sulphide (zinc).

The following tests have been adopted by the United States Pharmacopœia: 1 Gm. of the salt, heated with 50 Cc. of water to boiling and cooled, should yield a filtrate leaving, when evaporated to dryness on a water-bath, not more than 0.001 Gm. of residue (limit of foreign soluble salts). 10 Cc. of a solution of the salt (1 in 50) made by the aid of acetic acid, should not give more than a slight opalescence with ammonium oxalate test-solution within 5 minutes (limit of calcium). A solution of 1 Gm. of the salt in 20 Cc. of diluted hydrochloric acid should be colorless and not give an immediate blue coloration with potassium ferrocyanide solution (limit of iron), nor should another solution of the same strength be colored or made turbid by an equal volume of hydrogen sulphide solution, when kept corked at 35° C. (95° F.) for at least half an hour, either before or after rendering alkaline with ammonia water (absence of heavy metals). 1 Gm. of the salt when ignited in a porcelain crucible should leave a residue of not less than 0.4 Gm. If 0.400 Gm. of the recently ignited and cooled salt be dissolved in 25 Cc. of normal sulphuric acid, not more than 5.8 Cc. of normal alkali should be required to neutralize the excess of acid, methyl-orange test-solution being used as indicator (each Cc. of the acid consumed being equivalent to 0.02003 Gm. of MgO, or 5 per cent.).—U. S. 5 Gm. heated to redness should leave 2.1 Gm. of residue of oxide, corresponding to 42 per cent. (Br.). The theoretical per cent. of oxide obtainable from the U. S. formula is 41.53, from the Br. formula 41.9.

Action and Uses.—Magnesium carbonate is employed internally as an antacid in the treatment of gastric acidity and sick headaches. When the stomach or intestines are excessively acid, the drug is probably converted into a laxative salt. It is considered by some inferior to calcined magnesia because of the flatulence which may result from the liberation of carbon dioxide. Heavy magnesium carbonate may be given internally in doses of from 30 to 60 grains (2–4 Gm.); but if employed constantly there is danger of its accumulation in the intestines. Because of its bulk light magnesium carbonate is never employed in internal medicine. It is, however, largely used as a dusting-powder in intertrigo and similar conditions, and as a cosmetic.

Magnesium Carbonate Normal or Crystallized, $MgCO_3.3H_2O$, is formed when freshly precipitated basic carbonate is dissolved in water by the aid of carbon dioxide or potassium or sodium bicarbonate, and the solution is allowed to stand a day or two exposed to the air. It forms small, hard white crystals which lose a part of their carbon dioxide in the air. It is used principally in the preparation of mineral waters, and also as a substitute for the official carbonate when a very pure carbonate is desired; $1\frac{1}{2}$ parts of the crystallized salt are equal to 1 part of the ordinary carbonate.

MAGNESII CITRAS EFFERVESCENS.—Effervescent Magnesium Citrate.

Magnesium citricum effervescens, P. G.—*Limonade sèche au citrate de magnésie*, Fr.; *Brausemagnesia, Magnesiumcitrat in Körnern*, G.

Preparation.—Magnesium carbonate, 10 Gm.; citric acid, 46 Gm.; sodium bicarbonate, 34 Gm.; sugar, in No. 60 powder, 8 Gm.; alcohol, distilled water, each a sufficient quantity. Mix the magnesium carbonate intimately with 30 Gm. of citric acid and

4 Cc. of distilled water, so as to make a thick paste; dry this at a temperature not exceeding 30° C. (86° F.), and reduce it to a fine powder. Then mix it intimately with the sugar, the sodium bicarbonate, and the remainder of the citric acid, previously reduced to a very fine powder. Dampen the mass with a sufficient quantity of alcohol, and rub it through a No. 6 tinned-iron sieve, to form a coarse granular powder. Lastly, dry it in a moderately warm place, and keep in well-closed bottles.—U. S. (1890).

To prepare 1 pound of effervescent magnesium citrate the following quantities should be used: magnesium carbonate, 714 grains; citric acid, 7 avoirdupois ounces and 223 grains; 4 avoirdupois ounces and 390 grains of the citric acid should be used together with 5 drachms of distilled water to form the thick paste of acid magnesium citrate.

The formula of the German Pharmacopœia is like the preceding. The French Codex uses calcined magnesia 65, magnesium carbonate 60, citric acid 300, and sugar 600 parts.

In order to obtain a granular salt which is readily and completely soluble, it is important that the official directions be closely followed. The first step is the preparation at as low a temperature as possible of an acid magnesium citrate, a little less than one-half the citric acid ordered for this manipulation being sufficient for the formation of the normal salt. If the prescribed quantity of water and the temperature of 30° C. (86° F.) are exceeded, the far less soluble salt is likely to be produced, causing trouble in the finished product. The remainder of the citric acid should be powdered separately and then mixed, without pressure, with the sodium bicarbonate and sugar; lastly the finely powdered magnesium citrate is added. The citric acid necessary for complete decomposition of the alkali bicarbonate is derived in part from the acid magnesium salt; although this changes the character of the latter compound, its ready solubility is nevertheless preserved by the newly formed sodium citrate.

The addition of alcohol to the mixed powder should be made cautiously, only sufficient being used to enable the operator to form a mass which will permit of being rubbed through the meshes of the sieve. The subsequent drying of the granules must also be conducted with care, as the use of too high a heat will cause effervescence to take place, and thus destroy the granular condition of the salt. All granular effervescent salts containing sugar are apt to become discolored if made by the process recommended by the British Pharmacopœia, unless the heat necessary be carefully controlled.

Sieves of different degrees of fineness are usually used so as to obtain granules nearly uniform in size.

Properties.—This preparation forms white granules or a white granular inodorous powder having an acid reaction and a pleasantly saline and mildly acidulous refreshing taste. On exposure to air it attracts moisture, resulting in decomposition of the bicarbonate and the evolution of carbon dioxide, and afterward becomes damp without, however, completely deliquescing. It is nearly insoluble, or rather only partly soluble, in alcohol, but dissolves slowly and with copious, long-continued but not violent effervescence in 2 parts of water at 15° C. (59° F.); this solution is rarely perfectly clear, but usually is more or less opalescent from traces of impurities contained in the magnesium carbonate, and in the course of several days deposits crystals of magnesium citrate. Boiling water dissolves more rapidly a larger amount of the granules, and this solution separates on cooling a portion of the magnesium citrate in crystals. The total amount of citric acid ordered in the above formula is somewhat in excess (about 3.28 Gm.) of that required for the production of normal salts; this renders the taste pleasantly acidulous and the solution more permanent. The aqueous solution shows the reactions of citric acid and of magnesium salts; on boiling with test-solution of calcium chloride a white precipitate is produced; and the cold solution, on being rendered alkaline with ammonia water, yields with test-solution of sodium or ammonium phosphate a white precipitate which is readily soluble in acetic acid.

Action and Uses.—The properties of this salt are practically the same as those of its solution (see LIQUOR MAGNESII CITRATIS); but as it contains less acid than the latter, its taste is not so agreeable. It may be given in doses of from 1 to 3 drachms (4–12 Gm.), which should be dissolved in water and drunk during effervescence.

MAGNESII OXIDUM, *U. S.*—Magnesium Oxide; Magnesia.

Magnesia, U. S., 1890; *Magnesia levis*, Br.; *Magnesia usta*, P. G.; *Magnesia calcinata.*—*Calcined magnesia*, E.; *Magnésie, Magnésie calcinée*, Fr.; *Gebrannte Magnesia*, G.

Formula, MgO. Molecular weight, 40.06.

It should be kept in well-closed vessels, and contain, after ignition, not less than 96 per cent. of pure oxide.—U. S.

Preparation.—No detailed method is given in the pharmacopœias. Magnesia is prepared by exposing magnesium carbonate to low red heat in a covered crucible.

The Br. P. recognizes two varieties of magnesia—the heavy as *Magnesia ponderosa*, made from the heavy magnesium carbonate by the process just given, and *Magnesia levis* or *light magnesia*, which is made in precisely the same manner from the light magnesium carbonate. In the United States both kinds are extensively used, but when the heavy variety is desired, it is usually designated in prescriptions as *Magnesia ponderosa*, under which title it was recognized in the 1890 Pharmacopœia, while the light magnesia is designated simply as *Magnesia.*

The official magnesium carbonate consists of magnesium carbonate and hydroxide. On heating it, water and carbon dioxide are given off and magnesium oxide remains behind: $4(MgCO_3).Mg(OH)_2.5H_2O$ yields $5MgO + 4CO_2 + 6H_2O$. The magnesium carbonate is pressed somewhat firmly into a crucible, and this is placed in a suitable furnace, loosely covered with a lid, and then heated to dull redness. The expulsion of the water and carbon dioxide keeps the surface of the powder continually in motion, and there is no necessity of testing it as long as that motion is present; when the motion ceases a small quantity of the powder is taken from beneath the surface and near the center, mixed with sufficient water to displace the air, and then poured into an excess of dilute sulphuric acid. If no evolution of carbon dioxide takes place, the product is finished, and may be dipped out with a ladle, and the crucible filled with a fresh portion of magnesium carbonate without removing it from the furnace. The carbonate should not be raised to full red heat unless it be stirred constantly, otherwise the oxide will soon become dense and granular and with difficulty soluble in dilute acids. The yield is between 40 and 43 per cent. Magnesia of both kinds is now extensively made in this country, so that importation from England has very materially decreased.

Properties.—Magnesia is a white, very bulky, and very fine powder, without odor, and of an earthy, but destitute of a saline, taste. Exposed to a high heat, it becomes more compact, but does not fuse except before the oxyhydrogen blowpipe. According to Fresenius, it requires 55,000 parts of water for solution, and the liquid, like the moistened magnesia, has a distinct alkaline reaction. Its specific gravity varies between 2.3 and 3.3. When mixed with water it unites with it, forming a hydroxide having the composition $Mg(OH)_2$. Exposed to the atmosphere, a similar change takes place, but carbon dioxide is also absorbed and a corresponding quantity of oxycarbonate is formed. It should therefore be preserved in well-stoppered bottles. On stirring 1 part of magnesia with 15 parts of water in a beaker, and allowing the mixture to stand for about half an hour, it will form a gelatinous mass of sufficient firmness to prevent it from falling out when the glass is inverted; hence in suspending magnesia, sufficient water should be used to overcome this tendency, and the magnesia should always be added to the water, and not *vice versa.* Light magnesia should always be used for dispensing in water suspension. Heavy magnesia is smoother and denser than the light, and is preferred for use in powder mixtures. An ounce of light magnesia fills a 4-ounce bottle, while a like weight of heavy magnesia occupies about one-fourth the space.

Several proprietary articles, such as Henry's, Husband's, and others, consisting of heavy magnesia, were extensively used formerly. This magnesia was generally characterized by freedom from grittiness and ready miscibility with water, but it is not superior to a dense magnesia obtainable by careful manipulation from a properly prepared magnesium carbonate.

Tests.—A filtered solution of magnesia in diluted sulphuric acid, mixed with ammonium chloride test-solution and an excess of ammonia water, yields with sodium phosphate test-solution a white crystalline precipitate (ammonium-magnesium phosphate). If a mixture of 1 Gm. of magnesium oxide with 50 Cc. of water be heated to boiling, and, after cooling, filtered, the filtrate should not impart more than a faintly alkaline reaction

to red litmus-paper, and when evaporated to dryness should not leave more than 0.005 Gm. of residue (limit of foreign soluble salts). If a mixture of 0.1 Gm. of magnesium oxide, with 5 Cc. of water, be heated to boiling, and, after cooling, be poured into 5 Cc. of acetic acid, solution should take place without the evolution of more than a few isolated gas bubbles (limit of carbonate). 10 Cc. of a solution of magnesium oxide (1 in 50) prepared by the addition of sufficient acetic acid for solution, should not be rendered more than slightly opalescent within 5 minutes by ammonium oxalate test-solution (limit of calcium). If 1 Gm. of magnesium oxide be dissolved in 50 Cc. of diluted hydrochloric acid, the solution should be colorless and not give an immediate blue coloration upon the addition of potassium ferrocyanide test-solution (limit of iron), and a solution of magnesium oxide (1 in 20) in diluted hydrochloric acid, and warmed to about 50° C. (122° F.), should not be colored or rendered turbid by the addition of an equal volume of freshly prepared hydrogen test-solution, after standing, well-stoppered, in a warm place, 35° C. (95° F.) for at least half an hour, nor should the further addition of ammonia water to this solution cause a coloration therein (absence of heavy metals). If magnesium oxide be exposed to a low red heat in a porcelain crucible, it should not lose more than 15 per cent. of its weight (limit of water of hydration). If 0.400 Gm. of recently ignited and cooled magnesium oxide be dissolved in 25 Cc. of normal sulphuric acid, not more than 5.8 Cc. of normal potassium hydroxide solution should be required for neutralization, phenolphthalein test-solution being used as indicator (each Cc. of the normal sulphuric acid consumed being equivalent to 5 per cent. of pure magnesium oxide).—U. S.

Action and Uses.—Magnesia may be employed as a feeble laxative and antacid. It is thought by some to be beneficial in the treatment of gouty and dyspeptic conditions when attended with constipation and excessive gastric acidity. It may also be employed as an antidote to arsenic, and it enters into the official Ferri Oxidum Hydratum cum Magnesia. Under the name of Husband's Magnesia it is largely employed by the laity to overcome the excessive gastric acidity and constipation of infants. Magnesia should be administered in about 20 times its weight of water in order to prevent the formation of a gelatinous mass. The internal dose to an adult is from 15 to 30 grains (1–2 Gm.) as an antacid, and from 30 grains to 1 drachm (2–4 Gm.) as a laxative. Magnesia may also be employed as a dusting-powder for the treatment of superficial abrasions of the skin.

MAGNESII OXIDUM PONDEROSUM, *U. S.*—Heavy Magnesium Oxide; Heavy Magnesia.

Magnesia ponderosa, Br. (U. S. 1890).—*Magnésie calcinée pesante*, Fr.; *Schwere gebrannte Magnesia*, G.

Formula, MgO. Molecular weight, 40.06.

Preparation.—The process for preparing heavy magnesium oxide is identical with that mentioned under Magnesii Oxidum, except that heavy magnesium carbonate is used in place of the light article.

Properties and Tests.—Heavy magnesium oxide is a white, dense, and very fine powder, which should conform to the reactions and tests given under Magnesii Oxidum. It differs, however, from the latter in not readily uniting with water to form a gelatinous hydroxide.—U. S. When heated to dull redness it should lose little or no weight.—Br.

Pharmaceutical Uses.—Heavy magnesia, on account of its compact nature, is admirably adapted to admixture with other substances in powder form, but should not be used for liquid mixtures, for which latter purpose the light magnesia is better suited, especially for aqueous suspension.

Action and Uses.—The medicinal application of this preparation differs in no respect from that of the light oxide.

MAGNESII SULPHAS, *U. S., Br.*—Magnesium Sulphate.

Magnesium sulfuricum, P. G.; *Sal amarum, Sal Epsomense, Sal anglicum, Sal Sedlicense.—Sulphate of magnesia, Epsom Salt*, E.; *Sulfate de magnésie, Sel d'Epsom, Sel de Sedlitz, Sel amer*, Fr.; *Magnesiumsulfat, Bittersalz, Schwefelsaure Magnesia*, G.; *Solfato di magnesia*, It.; *Sulfato de magnesia*, Sp.

Formula, $MgSO_4 + 7H_2O$. Molecular weight, 244.69.

It should contain not less than 99.7 per cent. of the pure salt, and be kept in well-closed vessels.—U. S.

Origin and Preparation.—Magnesium sulphate is contained in sea water and in the waters of many mineral springs, which thereby acquire a bitter taste. The *Crab Orchard Salt* of Kentucky is the same salt in an impure state, and, as analyzed by J. T. Viley (1871), contains about 65 per cent. of magnesium sulphate after having been dried at 120° C. (248° F.). It probably results from the mutual decomposition of gypsum and magnesium limestone, and is obtained by evaporating the water which collects in wells dug in the ground. The pure salt is made on the large scale from *magnesite*, which is principally $MgCO_3$, by dissolving it in dilute sulphuric acid and crystallizing; large quantities of the salt are made by various processes from magnesian limestone, and more recently it is extensively obtained at the Stassfurt salt-works, principally from the mineral *kieserite*, which is $MgSO_4$ combined with varying quantities of water, and in its natural state as insoluble as gypsum. In 1897 the production of kieserite was nearly 26,000 tons. Magnesium sulphate was prepared as early as 1675, by evaporating the water of Epsom Spring, England. It was from this circumstance that the salt received its commercial name.

Properties.—As found in the market, magnesium sulphate has generally been purified by re-solution in water and rapid crystallization, and forms small rhombic prisms or needles, which resemble those of oxalic acid and zinc sulphate, are perfectly transparent, without odor, and have a cooling and bitter, saline taste, and a neutral reaction. It dissolves at 25° C. (77° F.) in 0.85 part of water, and in 0.13 part of boiling water (U. S.); it is also soluble in diluted alcohol, but insoluble in strong alcohol. The German Pharmacopœia gives the solubility of crystallized magnesium sulphate as 1 part in 1 part of water at 15° C., and in 0.3 part of boiling water. Exposed to air, the crystals slowly effloresce, becoming superficially opaque; when heated to 52° C. (125.6° F.) the salt loses 1 molecule (7.3 per cent.) of water, and is converted into a white powder. At about 130° C. (266° F.) it still retains 1 molecule of water, and at a temperature of 200° to 238° C. (392°–460.4° F.) it is rendered anhydrous (U. S.); the total weight of water amounts to 51.34 per cent. The aqueous solution on the addition of barium chloride yields a white precipitate of barium sulphate, insoluble in hydrochloric acid. It is not precipitated in the cold by potassium bicarbonate or ammonium carbonate, but gives white precipitates with the carbonates and the hydroxides of sodium and potassium, which are redissolved by ammonium chloride. Ammonia added to its solution likewise causes a white precipitate soluble in ammonium chloride, and this solution, on the addition of ammonium phosphate, deposits all magnesium in the form of a crystalline powder, which is magnesium and ammonium phosphate, $MgNH_4PO_4.6H_2O$, and is insoluble in diluted ammonia, sparingly soluble in water, and freely soluble in diluted acetic and other acids; the precipitate, after having been well washed with diluted ammonia, then dried, and ignited in a porcelain crucible, is converted into magnesium pyrophosphate, $Mg_2P_2O_7$ (molecular weight, 221.06), which represents 21.88 per cent. of Mg or 36.24 per cent. of MgO.

Tests.—Impurities are detected in precisely the same manner as in the solution of magnesium carbonate (see above). The following tests have been adopted by the U. S. P.: 10 Cc. of the aqueous solution of the salt (1 in 20), acidified with 1 Cc. of diluted hydrochloric acid, should not be colored or made turbid by an equal volume of hydrogen sulphide solution, when kept corked at 35° C. (95° F.) for at least half an hour, either before or after rendering alkaline with ammonia water (absence of heavy metals). 5 Cc. of the aqueous solution of the salt (1 in 10) should not respond to the modified Gutzeit's test for arsenic described under Arseni Trioxidum. 0.5 Gm. should yield 0.22 Gm. of magnesium pyrophosphate, corresponding to 15.93 per cent. of MgO (Br.). Theoretical percentage of oxide in magnesium sulphate is 16.37.

Magnesii Sulphas Exsiccatus. *Magnesium sulfuricum siccum*, P. G. *Dried magnesium sulphate. Getrocknetes Magnesiumsulfat.*—The crystallized sulphate is exposed in a warm place until it has lost from 35 to 37 per cent. of its weight, and is then passed through a sieve. It is a white powder having the properties of the crystallized salt, except that it contains less water; on exposure to air it gradually attracts moisture, and should therefore be kept in well-stoppered bottles. The German Pharmacopœia directs it to be dispensed when powdered magnesium sulphate is prescribed.

Action and Uses.—Magnesium sulphate when taken internally produces a watery stool if the dose is sufficient to move the bowels thoroughly. This action is due to the fact that it causes a more or less profuse flow of fluid to take place from the walls of the intestine by reason of the fact that the concentration of its solution is greater than that of the blood, and also because it is a substance very slowly absorbed, so that the greater part remains in the intestine, thereby maintaining the concentration of the solution except for the dilution caused by the outpouring of the fluid from the tissues just described. The greater its concentration in the presence of free fluid in the tissues, the greater the purgative effect; but if the tissues have been deprived of fluids, then the best effect is produced by giving it with a moderate amount of fluid, to give it bulk. Magnesium sulphate is used in medicine as a rapidly acting depletant purge, which will unload the bowel as a rule in a couple of hours at the latest. In cases of dropsy it is given in concentrated solution to relieve the general anasarca, and should be administered to the patient when fasting. In the various inflammations of the bowel and peritoneum it is useful both because it unloads the bowel and because it allays the inflammatory process by depleting the inflamed intestine. Magnesium sulphate is the most active ingredient of many natural purgative waters. It is used also as a purge whenever offensive matter is to be expelled from the alimentary canal.

The dose of sulphate of magnesium is about ½ ounce (16 Gm.), dissolved in half to one tumblerful of water, and taken before breakfast for its full effect. Sometimes 1 ounce (30 Gm.) is taken. The most active effects are produced by giving it in divided doses.

Sulphate of magnesium, if injected into the bloodvessels, produces death very rapidly. Introduced in this way it is to be considered a deadly poison.

MAGNESII SULPHAS EFFERVESCENS, *U. S., Br.*—Effervescent Magnesium Sulphate.

Magnesium sulphuricum effervescens.—Effervescent Epsom Salt, E.; *Brausendes Magnesiumsulfat*, G.

Preparation.—Take of magnesium sulphate in unefflorescd crystals, 500 Gm.; sodium bicarbonate, 403 Gm.; tartaric acid, 211 Gm.; citric acid, in unefflorescd crystals, 136 Gm. Dry the magnesium sulphate, on a water-bath, until it ceases to lose weight; after powdering the dry salt, mix it intimately with the citric and tartaric acids, then thoroughly incorporate the sodium bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated to between 93° and 104° C. (199.4° and 219.2° F.). When the mixture has acquired a moist consistence, by the aid of careful manipulation with a wooden spatula, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.).—U. S. The yield is about 1000 Gm.

By taking the ingredients in the above order and in the proportion of 5 ounces; 4 ounces, 13 grains; 2 ounces, 48 grains; 1 ounce, 157½ grains, respectively, the resulting product will weigh about 10 ounces.

The Br. P. preparation differs somewhat from the U. S. product, as may be seen from the following formula: Take of crystallized magnesium sulphate, 500 Gm.; sodium bicarbonate, 360 Gm,; tartaric acid, in powder, 190 Gm.; citric acid, in powder, 125 Gm.; refined sugar, in powder, 105 Gm. The magnesium sulphate is dried at 54.4° C. (130° F.) until it has lost 23 per cent. in weight, and is then powdered. It is mixed first with the sugar and then with the other ingredients. The mixture is heated between 93.3° and 104.4° C. (200° and 220° F.) until, by careful manipulation, it has assumed a granular form, after which it is separated by sieves into granules of uniform size and dried at a temperature not above 54.4° C. (130° F.). Weight of product, about 1000 Gm.

This preparation was made official in the U. S. P. of 1900, and represents 50 per cent. of crystallized magnesium sulphate. It should be kept in well-closed bottles.

Action and Uses.—This new salt possesses the properties of MAGNESII SULPHAS (which see). It is a more agreeable form for the administration of the remedy. The dose is from ½ to 1 ounce (16–30 Gm.), dissolved in water and swallowed during effervescence.

MAGNESIUM.—Magnesium.

Magnesium, Fr., G.

Symbol, Mg. Bivalent. Atomic weight, 24.18.

The compounds of magnesium show some resemblance to those of the alkaline earth metals, and also to those of zinc and cadmium. In the insolubility of the hydroxide and its easy decomposition by heat and slight alkaline reaction, and the ready solubility of the sulphate, magnesium stands very close to zinc. Its compounds are widely distributed, but are less abundant than those of calcium; it is found as silicate in *meerschaum, olivine, mica, serpentine*, and other minerals; as chloride in sea water and the waters of saline springs; and as carbonate in most spring and mineral waters, in *magnesite*, and in *dolomite* or magnesian limestone. Black (1755) first proved magnesia to be distinct from lime, and Davy (1808) isolated the metal, which is now generally prepared by modifications of the process elaborated by St. Claire-Deville and Caron (1856), by heating sodium with anhydrous magnesium chloride; the resulting sodium chloride is dissolved by water, and the magnesium left behind in the form of a gray powder, which is fused and moulded as desired. Instead of using the chloride, which it is difficult to prepare anhydrous in large quantity, *carnallite*, $KMgCl_3.6H_2O$, a mineral occurring in abundance in the German salt-beds, is employed, after thoroughly drying it, when it has the composition $KMgCl_3$. Magnesium is also largely prepared from molten carnallite by passing a strong electric current through it, whereby the metal separates at the negative pole.

Magnesium is silver-white with strong luster, malleable, fusible at a red, and volatile at a white heat. Its density is 1.78. It is not altered in dry air, but is slightly tarnished in damp air, and decomposes water actively at 100° C. (212° F.), hydrogen and magnesium hydroxide being formed. When heated in the air, it burns to the oxide, and gives an intensely brilliant white light, which, being rich in chemically active rays, is employed in photography. Sunlight is more than 500 times as strong in intensity, but only 5 times as strong in chemically active rays, as magnesium light. Magnesium is readily dissolved by acids. It occurs in the market in four forms, namely, powder, ribbon, wire, and bars. It is used on account of its intense light in signalling; also in fireworks and as a reducing agent in chemical processes.

Magnalium.—This is a name applied generically to alloys of aluminum containing 10 to 25 per cent. of magnesium, which have very valuable properties. Magnalium of 2–2.5 specific gravity is still lighter than aluminum, but at the same time much harder, and takes on a high polish. The properties of magnalium vary according to the content of magnesium.

COMPOUNDS OF MAGNESIUM.

Magnesii Acetas. *Magnesium acetate*, E.; *Acétate de magnésie*, Fr.; *Magnesiumacetat*, G. $Mg(C_2H_3O_2)_2.4H_2O$.—This salt may be obtained by neutralizing acetic acid with magnesium carbonate, filtering, and evaporating to crystallization. It is a white salt, easily soluble in water and alcohol, melts at 80° C. (176° F.) and deliquesces in moist air. It is employed commercially in the preparation of white lead because of its power to dissolve lead oxide, which is reprecipitated by passing carbon dioxide through the solution.

Magnesii Benzoas. *Magnesium benzoate*, E.; *Benzoate de magnesie*, Fr.; *Magnesiumbenzoat*, G. $Mg(C_7H_5O_2)_2.3H_2O$.—Obtained by neutralizing a hot solution of benzoic acid with oxide or carbonate of magnesium, and crystallizing. It is a white, crystalline, non-hygroscopic powder, soluble in 20 parts of water and the same amount of alcohol. It melts at 200° C. (392° F.), and when calcined, it gives off inflammable vapors of benzene and leaves 12.5 per cent. of oxide. It has been recommended for gout, urinary calculi, and tuberculosis. Dose, from 2.5 to 15 grains (0.125–1 Gm.).

Magnesii Bromidum. *Magnesium bromide*, E.; *Bromure de magnésie*, Fr.; *Magnesiumbromid*, G. $MgBr_2.6H_2O$.—Obtained by neutralizing hydrobromic acid with magnesium oxide, evaporating, and crystallizing in a desiccator. Colorless, very deliquescent crystals. It is used as a nervine, in the same manner and dose as potassium bromide. It is also employed in the manufacture of mineral waters.

Magnesii Lactas. *Magnesium lactate*, E.; *Lactate de magnésie*, Fr.; *Magnesiumlactat, Milchsaure Magnesia*, G. $Mg(C_3H_5O_3)_2.3H_2O$.—6 parts of calcium lactate (see page 71) and 5 parts of magnesium sulphate are separately dissolved in hot water, the solutions mixed and filtered from the precipitated calcium sulphate, the last traces of which are removed by

digesting with a little magnesium carbonate; the filtrate is then evaporated and crystallized. Magnesium lactate may also be conveniently prepared by adding an excess of magnesium carbonate to lactic acid diluted with water, filtering, and evaporating the solution to dryness on a water-bath. The salt forms white granular crystals or needles, is insoluble in alcohol, soluble in about 30 parts of cold and 6 parts of boiling water, and when heated is decomposed without melting. It is a mild laxative in doses of from 15 to 45 grains (1–3 Gm.), 3 or 4 times a day.

Magnesii Salicylas. *Magnesium salicylate*, E.; *Salicylate de magnésie*, Fr.; *Magnesiumsalicylat*, G. $Mg(C_6H_4(OH)CO_2)_2.4H_2O$.—Obtained in the usual way by neutralizing a hot solution of salicylic acid with iron-free magnesium carbonate, evaporating the solution, which should be slightly acid, to crystallization. It forms colorless or reddish crystals, stable in air, soluble in 10 parts of water and in alcohol, and gives the usual reactions for salicylic acid. According to Huchard, it is an excellent remedy in abdominal typhus in doses of from 15 to 20 grains (1–2 Gm.), 3 times daily.

Magnesii Sulphis. *Magnesium sulphite*, E.; *Sulfite de magnésie*, Fr.; *Magnesiumsulfit*, G. $MgSO_3.6H_2O$.—Obtained by leading sulphur dioxide into a suspension of magnesium carbonate in water until no more carbon dioxide is evolved, letting the mixture stand for some time, then filtering and washing the crystals with cold water, and drying on porous plates. It is a white powder, soluble in 80 parts of cold and 120 parts of boiling water, loses its water at 200° C. (392° F.), and at a higher temperature is decomposed into sulphate and oxide. On keeping, magnesium sulphate is gradually formed by oxidation. It should be kept in well-closed, full, small bottles. It has been recommended in typhus, puerperal fever, pyæmia, scarlet fever, etc., in doses of from 15 to 30 grains (1–2 Gm.), in powder 5 to 8 times daily.

Asbestos is a name given to a variety of soft fibrous minerals, which are metamorphic products of augite and hornblende minerals, consisting chiefly of magnesium silicate. It is insoluble in reagents, incombustible, and poorly conducting, which properties make it useful in a variety of ways. It is admirably adapted as a filtering medium.

A number of magnesium salts, not mentioned above, have been proposed for various purposes. Some of these are borate, borocitrate, glycerophosphate, ichthyolate loretinate, phenolsulphonate, sozoiodolate.

MAGNOLIA.—Magnolia Bark.

Magnolienrinde, G.; *Écorce de magnolier*, Fr.; *Corteza de Laurel-tulipan*, Sp.

The dried bark of various species of *Magnolia* L. (Fam. *Magnoliaceæ*).

The genus comprises some 21 species, and all are apparently closely similar in composition and properties. Several species grow in the southeastern United States. The bark was formerly official in the U. S. Pharmacopœia, and was accredited to *M. Virginiana* L. (*M. glauca* L.), the *Small, Sweet, Swamp,* or *Laurel magnolia, Sweet* or *White bay, Swamp laurel* or *Sassafras* or *Beaver tree*, which extends along the coast from Texas to Massachusetts, is a deciduous shrub in the north, and an evergreen tree in the south, bears large oblong leaves which are very glaucous underneath, and small, white, very fragrant flowers; *M. tripetela* L. (*M. Umbrella* Lam.), the *Umbrella tree* or *Cucumber tree*, a large deciduous-leaved tree, bearing large leaves in an umbrella-like whorl at the ends of the branchlets, and large white flowers; and *M. acuminata* L. (*M. Virginiana acuminata* L.), the *Mountain magnolia* or *Cucumber tree*, which bears shortly acuminate leaves and yellowish-green flowers with a peculiar bluish tinge.

Description.—The commercial bark varies most widely, according to the species, the age, and the presence or absence of the corky layer, so that a general description is extremely difficult. The outer surface of old bark of all species is more or less ashy-gray, due to the growth of lichens. When young, it is smooth or even glossy and of a brown color, varying more or less to orange or purplish-red. With age, it gradually becomes warty, the warts at length confluent into ridges and the ridges at length fissured. The inner surface is at first whitish, becoming gradually yellowish or pale-brown, smooth, and very finely and closely striate, the striæ long and straight. When the bark has been deprived of the corky layer, the outer surface is almost exactly like the inner. In young bark, however, a green layer appears upon the removal of the cork. The fracture of the outer layer is smooth, short, and granular, of the inner more or less tough-fibrous. The transverse section is brownish and exhibits rather broad bast-wedges and medullary rays. The odor is slight, the taste warm, spicy, and somewhat astringent and, especially of the young bark, bitter.

Constituents.—Both the bark and the fruit (the latter from *M. tripetala*) contain *magnolin*, an odorless crystalline principle, with taste at first slight and later irritant,

nearly insoluble in cold but slightly soluble in hot water, and very soluble in alcohol. ether, chloroform, benzin, and carbon bisulphide. It is analogous to *liriodendrin*, and is probably present in all the commercial magnolia barks. Besides this, there have been found volatile oil, tannin, starch, sugar, and in the bark of *M. glauca*, 3 uncrystallizable resins, a crystalline glucoside soluble in alcohol and ether, and a crystalline tasteless body soluble in alcohol, chloroform, ether, and alkalies, the solution showing a blue fluorescence. The remaining material gives alkaloidal reactions, but no alkaloid could be isolated (Lloyd). The leaves yield a bitter glucoside and a bright-green volatile oil of sweetish fennel-like odor. The pungent taste of the fruit is due to a soft resin, and the odor to a little volatile oil.

Action and Uses.—Magnolia has been employed for its tonic, stimulant, and diaphoretic properties. Like other bitters, it may be employed in the treatment of malarial fever, and it is thought by some to be a valuable remedy for rheumatism. The dose of the powdered drug in substance is from ½ to 1 drachm (2–4 Gm.). A saturated tincture made by maceration in brandy may be given in doses of 1 fluidrachm (4 Cc.).

Other Species.—In China and Japan, the buds and seeds of *M. conspicua* Salisb. (*M. Yulan* Desf.) are used under the names *Shin-i* and *Ying-chun-hwa*, as aromatic bitters; the bark of *M. rubra* is the *Ch'ih-p'oh;* that of *M. hypoleuca* S. et Z. is *Hau-p'oh;* that of *M. Kobus* DC. (*M. gracilis* Salisb.) is *Opke-nit* or *Onan kusk-ni*.

Magnoliaceæ.—This family, of some 9 genera and about 70 species, shares generally in the aromatic-bitter properties of Magnolia, and a number of its members are similarly employed. Next to Magnolia, its most important drug is the following:

Liriodendron, or *Tulip-tree bark*, is the dried bark of *Liriodendron Tulipifera* L., the *Tulip tree, White-wood, Yellow, White, Blue, Hickory*, or *Tulip poplar, Saddle-leaf* or *-tree, Lyre-tree* (*Tulipenbaum*, G.; *Tulipier*, Fr.), one of the very largest trees of eastern and central North America and occurring also in China. Its peculiar leaves well distinguish it. They are very smooth, about as broad as long, rounded at the base and with a broadly notched or occasionally truncate summit. It bears large, tulip-like, greenish-yellow flowers, striped with orange-red. The bark is similar in structure, odor, and taste to that of Magnolia. The outer surface is darker, usually of a very dark-purplish or blackish-brown, and in the older bark more deeply fissured. The inner bark is usually more nearly white than that of Magnolia. Like Magnolia, it contains volatile oil and a bitter principle. The latter is *liriodendrin*, which occurs in white needles, melting at 82° C. (180° F.), is neutral, scarcely soluble in cold water, but soluble in alcohol and in ether. It is precipitated by caustic alkalies and gives an orange-yellow color with sulphuric acid, none with nitric acid, and volatilizes, partly undecomposed, near 132° C. (270° F.). Lloyd describes the colorless, odorless, and tasteless alkaloid *tulipiferine*, which apparently does not affect its medicinal properties, and Coblentz reports a glucoside. Resin is present in variable amount. The properties and uses of Tulip-tree bark are practically identical with those of Magnolia.

Talauma.—A number of species of this genus, closely related to Liriodendron, are similarly employed. *T. macrocarpa* Zucc. is the Mexican *Yoloxochitle*.

Michœlia champaca L. (*M. rufinervis* DC.; *M. Doltsopa* Ham.), of the East Indies, and cultivated in various tropical countries, yields an important aromatic bitter bark, largely used under many local names: *Champa, Champo*, or *Shampang*, in India; *Chenpoh, Chen-p'o-kia*, in China; *Tsampaka*, in the Philippines. Its volatile oil yields a camphor which has been called *campacol*. Several other species of the genus yield barks which have also been called *champaca*, or by names having a similar sound.

MALLEIN.

Mallein is a glycerin extract of the soluble substances produced by the glanders bacillus when grown in 5 per cent. glycerin-beef bouillon.

Löffler and Schultz proved that glanders or farcy (*Morve*, Fr.; *Rotz*, G.), a disease attacking horses, donkeys, mules, etc., was due to a microörganism which they called *Bacillus Mallei*. Subsequent investigations showed that the subcutaneous injection of the soluble product of potato, bouillon, or other cultures of the germs, produced tumefaction at the point of injection and a marked rise of temperature in animals affected with the disease, and but very slight symptoms in unaffected animals.

While many methods have been employed in the past for producing mallein, the following is the one generally employed at present: Flasks of beef-bouillon (see ANTITOXINS), containing 5 per cent. of glycerin, are planted with virulent cultures of *B.*

Mallei, placed in an incubator kept at 37.5° C. (99° F.), and allowed to remain for several weeks, when they are examined microscopically, and, if found pure, are sterilized by heat at 100° (212° F.). The culture is then filtered through porcelain, which removes all bacteria, and usually concentrated to one-tenth of its volume. The resulting dark syrupy glycerin extract is the concentrated mallein found on the market. This concentrated product may be purified by precipitating with 95 per cent. alcohol, collecting the precipitate, and drying. Occasionally 0.5 per cent. carbolic acid is added to the unconcentrated culture, and marketed in that form, when it is called *Dilute Mallein.*

Mallein is a fairly stable product, but should not be exposed to light.

Uses.—Mallein is injected into horses, donkeys, mules, etc., to determine whether they are infected with glanders. 1 to 2 Cc. of the concentrated mallein are diluted with a 0.5 per cent. carbolic acid solution, and injected subcutaneously behind the shoulder of the animal. The temperature of the animal should be carefully determined before the injection. If the animal be infected with glanders, a rise of temperature, beginning usually about 8 hours after the injection is made, of 1.5 to 3 degrees above normal occurs, lasting from 12 to 48 hours, accompanied by marked sensitive tumefaction at the point of injection.

MALTUM, *U. S., P. A.*—Malt.

Maltum hordei.—Barley Malt, E.; *Malz, Gerstenmalz*, G.; *Malt d'orge, Drêche*, Fr. The seed of barley, *Hordeum distichum* L. (Fam. *Gramineæ*), partially germinated artificially, and then dried.

Preparation and Properties.—The grain is soaked in water and then placed in heaps; heat is spontaneously generated and, by occasional turning, is prevented from rising too high. Under these conditions, germination takes place, and when the germ has acquired the desired length, the grain is rapidly dried, the sprouts being then removed, and constitutes *malt.* According to the degree of heat employed in drying, the color of the malt varies somewhat, and is known as either "pale," "pale-amber," or "amber-brown." For some purposes, malt is made to undergo a roasting process in revolving cylinders, to obtain roasted or black malt if the integuments only are of a dark-brown color, or crystallized malt if the interior of the grain has become dark-brown. Only pale or pale-amber malt is used medicinally. The grain is increased about 9 per cent. in size, but loses about 20 per cent. in weight, and becomes soft and easily crumbled. Malt has an agreeable odor and a sweet taste, and yields with water a more or less deep yellowish-brown or brown infusion. About two-thirds of it is soluble in water.

Properties.—Malt occurs in yellowish or amber-colored grains, shading to brown; crisp when fractured, the interior surface whitish or tinged with brown if the grains have been heated sufficiently to cause caramelization. It should have an agreeable, characteristic odor, and a sweet taste due to the conversion of the starch in the seed into maltose, through the action of diastase. Malt should float on cold water. The solid soluble constituents of malt, obtained by evaporating an aqueous infusion to dryness, should weigh not less than 70 per cent. of the dried malt from which they are derived. The acidity of malt (calculated as lactic acid) should not exceed 0.3 per cent.—U. S.

Constituents.—Almost the first chemical change in the germinating barley is the development in it, from an imperfectly known substance, of the ferment or enzyme *diastase*, which is known only by its effects. It is supposed to exist to the extent of about 0.2 per cent. During the continuation of the process, the diastase converts a large part of the starch into sugar. A second ferment, *peptose*, is also produced, and this converts the albumen into peptones. In other respects, the composition of malt does not differ essentially from that of barley (see HORDEUM). By grinding and infusing (*mashing*) and maintaining this *wort* at 70° C. (158° F.), nearly all of the remaining starch is likewise converted.

By an improvement over the oriental method of fermenting rice to make *Arrack* (rice beer), it is now proposed to convert rice into malt for beer-making, and the experiment is under trial in Germany.

Pharmaceutical Preparations.—EXTRACT OF MALT, U. S. P.; FLUIDEXTRACT OF MALT, N. F.

Action and Uses.—Malt depends for its activity upon the diastase and peptose which it contains. In the form of EXTRACTUM MALTI (which see) it may be employed as an adjunct to the diet of that class of patients whose digestion is impaired by certain chronic constitutional diseases such as tuberculosis and marasmus. It is also said to be valuable in the treatment of cholera infantum and the summer diarrhœa of infants.

MALVACEÆ.—The Mallow Family.

The Mallow family, comprising 33 recognized genera and about 1000 species, occurring mostly in tropical and warm-temperate regions, is of economic interest chiefly in the following four directions: It contributes a large number of ornamental flowering plants (Abutilon, Hibiscus, Hollyhock, etc.). Its bast-fibers are usually tough, some of them with special properties, and a number have been utilized for cordage, as have the hairs of the seeds of others (see GOSSYPIUM). Several yield important starchy and mucilaginous foods (Althæa, Okra, etc.). Many species have been employed medicinally, chiefly for their mucilage, giving them value for poultices, and as demulcents. A great many are diuretic, and these diuretic properties are of peculiar interest, since combined with a demulcent action. Special properties occur, as in cotton-root bark, but are rare. With the facts stated above in view, little else is called for than an enumeration of the drugs, with brief descriptions of the more important of them. The decline in the once general and ignorantly confident use of these drugs has been coincident with and indicative of the development of the scientific basis of modern medicine.

FIG. 266.

Althæa leaf (¼ Nat.).

ALTHÆA LEAVES, or *Marshmallow leaves* (*Folia Althææ*, P. G., P. A.; *Feuilles de guimauve*, Fr. Cod.; *Eibischblätter*, *Althee*, G.), are the dried leaves of *Althæa officinalis* L. (see ALTHÆA). They are petiolate, 5 to 8 Cm. (2–3 In.) long, roundish-ovate or subcordate, 3- or 5-lobed, irregularly crenately toothed, of a grayish-green color, and both sides velvety-downy with stellate hairs, the taste mucilaginous. The *flowers* of this species (*Fleurs de guimauve*, Fr. Cod.) are somewhat employed like the next. They have a 9-leaved downy epicalyx, 5 sepals and petals, the latter rose-colored and retuse above; stamens numerous, united in a column and with the short claws of the petals; taste mucilaginous.

Flores Malvæ Arboreæ or *Flores Althææ* (*Hollyhock flowers*, *Althea rose*, E.; *Stockrose*, *Stockmalve*, G.; *Passerose*, *Rose trêmière*, Fr.) are the dried flowers of *Althæa rosea* (L.) Cav. (*Alcea r.* L.), native of the Levant and everywhere cultivated for ornament. The tomentose, yellowish-green or whitish-green, 6-cleft epicalyx and calyx should be removed before using. The corolla, of 5 broad, usually retuse petals, coherent at the base, is 7 to 10 Cm. (3 to 4 In.) broad and of a very deep-purple color. The numerous stamens are coherent with a cylindrical tube for most of their length and adherent to the base of the petals. They are valued for their purple coloring-matter as well as for their mucilage.

Flores Malvæ (P. G.) or *F. M. vulgaris* (*Blue malva flowers*, *High mallow flowers*, E.; *Waldmalve*, *Kaesepappel*, *Malvenbluethen*, G.; *Mauve sauvage*, *Grande mauve*, Fr.) are the flowers of *Malva sylvestris* L., the *High* or *Common mallow*, *Cheese* or *Cheese-cake flower* or *Pan-cake plant*, of the same region as that of the last, cultivated in gardens and somewhat naturalized in the United States. The entire herb is sometimes used. It has an erect or decumbent stem 0.75 M. (about 2½ Ft.) high, roundish-reniform, 5- or 7-lobed and crenately toothed leaves, and purplish, dark-veined flowers, which resemble the preceding, but are only 25 Mm. (1 In.) wide and have a pubescent 3-leaved epicalyx. The dried flowers are bluish, and turn green with ammonia and red with acids. This flower is rather more valued for its coloring than for its demulcent properties.

The herbage, and more so the leaves, of the above and also of *M. vulgaris* Fries (*M. neglecta* Wallr.) are the *Folia Malvæ*, P. G. (*Mallow leaves*, E.; *Malvenblätter*, G.; *Feuilles de mauve*, Fr.; *Malva*, Sp.). The species last named has a procumbent stem, smaller, obtusely lobed leaves, and rose-colored or whitish flowers.

Malva rotundifolia L. is the *Low*, *Dwarf*, or *Running mallow*, *Cheesies*, *Doll-* or *Fairy-cheeses*, E.; *Kaesekraut*, G.; *Petite mauve*, Fr., and is very commonly naturalized in the United States. It has a procumbent stem, round, heart-shaped, somewhat lobed and crenate leaves, whitish flowers with slightly retuse, rather short petals, and numerous wrinkled 1-seeded carpels, circularly arranged.

Semen Abelmosehi, *Grana Moschata*, or *Semen Alceæ Ægytiaceæ* (*Abelmoschus* or *Musk-seed*, *Amber-seed*, *Ambrette*, E.; *Moschuskoerner*, *Bisamkoerner*, G.; *Graine de muse*, *Ambretta*, Fr.), are the seeds of *Hibiscus Abelmoschus* L. (*H. moschutus* Moench), of Egypt and India, and

widely cultivated. These seeds are flattish reniform, about 3 Mm. (⅛ In.) long, grayish brown, concentrically striate, blackish at the hilum, internally whitish and oily, and have a thin endosperm and curved embryo. The strong musk-like odor resides in the testa, and becomes more apparent on rubbing or warming. The seeds are used in perfumery as a substitute for musk. The distilled oil contains acetic and palmitic acids, and when freed from the fat acid remains liquid at 0° C.

The calyx of the flower of *Hibisena Sabdariffa* L.; the *Red sorrell* or *Roselle* (E.), *Oseille de Grimée, Ketmie acide* (Fr.), of Africa, and cultivated in warm countries, is sour from the presence of tartaric and malic (or oxalic?) acids, and is thus used as a refrigerant, as well as for its mucilage, in Mexico, under the name of *Jamaica*. The root of *H. Rosa-Sinensis* L., or *China rose*, a beautiful decorative plant, is used like *Althea* root in China. The herbage and flowers of *Abutilon Abutilon* (L.) Rusby (*Sida A.* L.; *A. Avicennæ* Gærtn., the *American jute, Indian mallow, Velvet-leaf*, etc.) are employed for their mucilaginous properties, and the fiber as a substitute for hemp or jute.

The seeds of *Abutilon Indium* (L.) Sweet (*Tung-kwei-tsze*) are used in China like Abelmoschus, and the bark in India, under many names, as a diuretic.

Thespesia populnea Carr. is the *Babing gabut* of the Philippines. The yellow juice of the fruit is applied for itch and other skin diseases. The bark is astringent.

The root of *Abroma angusta* Lam. is used in India as an emmenagogue, and has, apparently, properties similar to those of cotton-root bark.

Sida lanceolata Retz., of southern Asia, has a bitter root which is used as a diuretic. The herbage of several other species of this genus is similarly employed, and that of *S. carpinifolia* L. widely diffused through the tropics, is said to be insecticidal. Several species of *Pavonia* are used as diuretics in South America.

The pulp surrounding the seeds of *Adansonia digitata* L. (Fam. *Bombacaceæ*), the *Baobab, Cream of tartar tree* or *Sour gourd tree*, of tropical Africa and the East Indies, has acid properties similar to those of the calyx of *Hibiscus Sabdariffa*, mentioned above. The fruit, under the name of *Monkey-bread*, or *Sour gourd*, is used in the East Indies as a refrigerant and appetizer, and was at one time reported, evidently without reason, as an antiperiodic.

MANGANI DIOXIDUM PRÆCIPITATUM, *U. S.*—Precipitated Manganese Dioxide.

Bioxyde (Peroxyde) de manganèse précipité, Fr.; *Präcipitistes Mangandioxyd*, G.

This is chiefly manganese dioxide ($MnO_2 = 86.36$), with small amounts of other oxides of manganese, corresponding to not less than 80 per cent. of manganese dioxide. —U. S. It was introduced into the Pharmacopœia of 1900 as suitable for internal use, being formed by precipitation and thus free from foreign matter, which renders the native dioxide unfit for this purpose.

Preparation.—Manganese sulphate, 50 Gm.; ammonia water, 250 Cc.; solution of hydrogen dioxide, 250 Cc. Dissolve the manganese sulphate in 1000 Cc. of distilled water. Dilute the 250 Cc. of ammonia water with an equal volume of distilled water, and mix with the 250 Cc. of hydrogen dioxide solution, which has likewise been diluted with an equal volume of distilled water. Pour this mixture slowly with constant stirring into the solution of the manganese sulphate. Allow the mixture to stand for 1 hour, stirring frequently. Then decant the supernatant clear liquid from the precipitate, and wash the latter repeatedly by the affusion and decantation of distilled water, using 1000 Cc. of hot water each time. Collect the precipitate on a plain filter and continue the washing with hot distilled water until the washings no longer have an alkaline reaction upon litmus-paper, nor react with barium chloride test-solution. Allow the precipitate to drain and dry at 150° C. (302° F.).—U. S.

Properties and Tests.—A heavy, very fine, odorless, tasteless, black powder, which is permanent in the air, insoluble in water or alcohol. It is not affected by cold concentrated sulphuric acid, but when heated with the latter it is converted into manganous sulphate with evolution of oxygen. When heated with hydrochloric acid, it is converted into manganous chloride, with the evolution of chlorine. At a red-heat precipitated manganese dioxide gives off oxygen, and is converted into reddish-brown manganoso-manganic oxide (Mn_3O_4). On intimately mixing 1 part of the dioxide with 1 part of potassium hydroxide and 1 part of potassium chlorate, introducing the mass into a crucible, moistening with water, drying and igniting, a dark fused mass is obtained, which yields, with water, a green solution, changing to purplish red on being boiled, or on the

addition of diluted sulphuric acid. If to 1 Gm. of the dioxide and 2 Gm. of oxalic acid, 20 Cc. of water be added, followed by 3 Cc. of sulphuric acid, and the mixture digested for several hours on a water-bath, complete solution should be effected (absence of antimony sulphide and insoluble substances). If 0.2 Gm. of precipitated manganese dioxide be dissolved in a mixture of 50 Cc. of tenth-normal oxalic acid solution, and 3 Cc. of sulphuric acid contained in a flask and heated on a water-bath, the resulting solution, after dilution with 100 Cc. of warm water, should require the addition of not more than 13 (12.95) Cc. of tenth-normal potassium permanganate solution to produce a slight pink tint (corresponding to not less than 80 per cent. of pure manganese dioxide). —U. S. Since 86.36 parts of pure manganese dioxide are capable of oxidizing 125.10 parts of crystallized oxalic acid, as shown by the equation $MnO_2 + H_2C_2O_4.2H_2O + H_2SO_4 = 2CO_2 + MnSO_4 + 4H_2O$, it follows that 1 Cc. of tenth-normal oxalic acid solution (containing 0.006255 Gm. of the acid) will require 0.004318 Gm. of manganese dioxide. As the Pharmacopœia demands that 0.2 Gm. of manganese dioxide shall oxidize not less than 37 Cc. of tenth-normal oxalic acid solution, this would indicate at least 80 per cent. of pure MnO_2, for $0.004318 \times 37 = 0.159766$ and 80 per cent. of 0.2 is 0.160.

The above method of precipitation was proposed by Jannasch, and when carried out as described yields a product of fairly constant composition which is approximately represented by the formula, $4MnO.(20 \text{ to } 25\ MnO_2)$. The proportion of manganese oxide present varies largely with the temperature of drying; at 210° C. (410° F.) the precipitate begins to lose oxygen, but some water of hydration is still retained at this temperature. The manganous oxide is also increased if the manganese sulphate solution is poured into the alkaline solution. The effect of the hydrogen dioxide is to oxidize the precipitated manganous hydroxide, $Mn(OH)_2$, forming in large part $Mn(OH)_4$; thus $Mn(OH)_2 + H_2O_2 = Mn(OH)_4$ or $MnO_2.2H_2O$. The water of hydration is nearly all driven off in drying at 150° C.

Commercial manganese dioxide, also known as black oxide of manganese, or pyrolusite, is no longer recognized in any of the pharmacopœias. It is found in different parts of Russia, Germany, France, Spain, and Great Britain, and also in Nova Scotia, Vermont, Pennsylvania, and other parts of North America. Sometimes it is found nearly pure, but it is generally associated with other manganic ores, particularly with the inferior brown manganite, and often with iron, lime, baryta, silica, etc. Pyrolusite is the most important and most abundant manganese mineral. When pure it consists of 63.19 per cent. of manganese and 36.81 per cent. of oxygen. The only use to which black oxide of manganese is put in pharmacy is in the preparation of pure chlorine water, and for this purpose it should contain at least 65 to 70 per cent. of manganese dioxide, which may be determined by the following method of assay given in the 1890 Pharmacopœia: To 1 Gm. of the finely powdered black oxide of manganese contained in a small long-necked flask add 5 Cc. of water and 4.22 Gm. of ferrous sulphate in clear crystals; subsequently 5 Cc. of hydrochloric acid are added and the mixture digested for about 15 minutes at a gentle heat and finally heated to boiling. After the mixture has been filtered and cooled, it should be immediately tested with freshly prepared potassium ferricyanide test-solution, when a blue color should not be produced (showing the presence of at least 66 per cent. of manganese dioxide). The reaction consists in oxidation of the ferrous salt to the ferric state, as shown by the following equation: $3MnO_2 + 12HCl + 6(FeSO_4 + 7H_2O) = 2Fe_2(SO_4)_3 + Fe_2Cl_6 + 3MnCl_2 + 48H_2O$. 1 Gm. of absolute manganese dioxide is capable of completely oxidizing 6.398 Gm. of crystallized ferrous sulphate.

Besides its use for the manufacture of chlorine water, black oxide of manganese is also used to generate oxygen in mixture with potassium chlorate. For the latter purpose the dioxide must be free from impurities of organic (combustible) matter, carbon, antimony sulphide, etc., since the presence of these may cause violent explosions when the oxygen mixture is heated.

Action and Uses.—Binoxide of manganese is said to possess tonic and alterative properties, but at the present time it is seldom employed. It has been recommended in the treatment of syphilis, scurvy, and secondary anæmias. An ointment containing from 10 to 15 per cent. of the drug in benzoinated lard may be tried as a remedy for parasitic skin diseases. Its principal employment at the present time is in the treatment of amenorrhœa, and it is said to be especially valuable when this condition is the result of functional nervous disturbance or anæmia. The dose is from 3 to 10 grains (0.20–0.60 Gm.), 3 times daily.

MANGANI HYPOPHOSPHIS, *U. S.*—Manganese Hypophosphite.

Manganum hypophosphorosum.—Manganous hypophosphite, E.; *Hypophosphite de manganèse, Hypophosphite manganeux*, Fr.; *Unterphosphorigsaures Manganoxydul*, G.

Formula, $Mn(PH_2O_2)_2.H_2O$. Molecular weight, 201.54.

It should contain not less than 97 per cent. of the pure salt, $Mn(PH_2O)_2$, and be kept in well-stoppered bottles.—U. S.

Preparation.—The salt is of interest chiefly on account of its use in the preparation of the official *compound syrup of hypophosphites*. It may be made by mixing a solution of 1 part of calcium hypophosphite with a solution of 1.31 parts of manganese sulphate, stirring well, and setting aside in a warm place to allow the resulting calcium sulphate to separate, after which the solution is filtered and evaporated, or allowed to crystallize.

Properties.—The salt occurs as a pink, crystalline, odorless, and nearly tasteless powder, permanent in the air. It is almost insoluble in alcohol, but soluble in 6.6 parts of water at 25° C. (77° F.), and in 6 parts of boiling water. The solution in water is neutral to litmus-paper, and gives with ammonium sulphide solution a salmon-colored precipitate of manganese sulphide, soluble in acetic acid. When strongly heated, spontaneously inflammable hydrogen phosphide is given off and a residue of manganous pyrophosphate remains. It is readily oxidized by nitric acid and other oxidizing agents. Like all hypophosphites, it reduces mercuric chloride, acidulated with hydrochloric acid, to mercurous chloride, and finally to dark metallic mercury.

Tests.—No effervescence should occur if 0.5 Gm. of the salt be added to 5 Cc. of acetic acid (absence of carbonate). If 0.5 Gm. of the salt be boiled with 10 Cc. of potassium hydroxide test-solution, and the flesh-colored precipitate, which gradually turns brown in the air, be filtered, the liquid, after slight acidulation with hydrochloric acid and then rendering alkaline with ammonia water, should yield no precipitate in one portion with magnesia mixture (absence of phosphate), nor with ammonium oxalate solution in the other portion (absence of calcium). If 5 Cc. of the aqueous solution of the salt (1 in 10) be mixed with 3 Cc. of nitric acid diluted with about 10 Cc. of water and evaporated in a beaker to dryness on a water-bath, the residue should not respond to the modified Gutzeit's test for arsenic described under ARSENI TRIOXIDUM.

Action and Uses.—The uses and dose of manganese hypophosphite are the same as of CALCIUM HYPOPHOSPHITE (which see).

MANGANI SULPHAS, *U. S.*—Manganese Sulphate.

Manganum sulfuricum, Manganous sulphate, E.; *Sulfate de manganèse, Sulfate manganeux*, Fr.; *Manganosulfat, Schwefelsaures Mangan (oxydul)*, G.

Formula, $MnSO_4 + 4H_2O$. Molecular weight, 221.47.

It should contain not less than 99.5 per cent. of pure salt, and be kept in well-stoppered bottles.—U. S.

Preparation.—Manganese dioxide is mixed with sufficient strong sulphuric acid to obtain a thin magma, which is heated to boiling and evaporated to dryness; the mass is now heated in a crucible to dull redness for some time, for the purpose of decomposing the iron sulphate. When cool, it is treated with water, and the solution, if iron be still present, digested with manganous carbonate, then filtered and evaporated to crystallize. By the warm digestion the iron is converted into a ferric compound, which is precipitated as ferric hydroxide by the manganese carbonate, some of which goes into solution as sulphate.

The salt may also be prepared from the solution of manganese chloride obtained in the preparation of chlorine, either by adding sulphuric acid, evaporating to dryness, and calcining as above, or by precipitating the solution with sodium carbonate, and dissolving three-fourths of the manganese carbonate in sulphuric acid and digesting the solution with the remaining carbonate to remove iron.

Properties.—When crystallized below 6° C. (43° F.) the salt contains 7 molecules of water, and is isomorphous with ferrous sulphate; above that temperature and below 20° C. (68° F.) it contains only 5 molecules of water, and has the

crystalline form of copper sulphate. But the salt usually met with is crystallized between 20° and 30° C. (68°–86° F.), and forms right rhombic—or, according to Marignac, monoclinic—prisms, containing $4H_2O$, 3 molecules of which are given off at a temperature of 115° C. (239° F.). A salt of the same composition as this residue is also obtained by adding sulphuric acid to a solution of manganous sulphate and evaporating; it forms a granular powder. The crystals of the official salt are transparent and colorless, or more frequently of a pale rose-red color, slightly efflorescent in a dry atmosphere, insoluble in strong alcohol, but dissolve at 15° C. (59° F.) in 150 parts of 60 per cent., in 50 parts of 50 per cent., and in 2 parts of 10 per cent. alcohol. The salt requires at 25° C. (77° F.) 0.7 part of water, and 0.53 part of boiling water (U. S.). The solution has a styptic and slightly bitter taste, a neutral or faintly acid reaction, and yields with ammonium sulphide a flesh-colored precipitate (manganese sulphide), with ferrocyanide a white one, and with ferricyanide a grayish-brown one, but is not disturbed by tannic acid. The fixed alkalies and alkali carbonates produce white precipitates (hydroxide and carbonate), which on exposure to air are rapidly oxidized, turning brown. Barium chloride yields an insoluble white precipitate (sulphate). If a fragment of the salt be mixed with a little sodium hydroxide test-solution, and the mixture then dried and fused, it will yield a dark-green mass of sodium manganate, Na_2MnO_4, dissolving in water with a green color.

Tests.—The most common impurity likely to be met with is sulphate of iron. The aqueous solution (1 in 20), after adding a few drops of hydrochloric acid and a little chlorine water, should, after boiling, not be colored red by potassium sulphocyanide test-solution (absence of iron). Sulphate of copper would in the slightly acidulated solution produce a black precipitate with hydrogen sulphide (a yellow precipitate indicates arsenic). The precipitate with ammonium sulphide should be completely soluble in acetic acid, proving the absence of zinc salt. The sulphates of magnesium and the fixed alkalies are indicated by the residue left after precipitating the solution completely with ammonium sulphide or carbonate, evaporating the filtrate to dryness, and igniting. When heated to dull redness, the salt should lose not more than 32.3 per cent. of its weight (proper—official—amount of water of crystallization).

Action and Uses.—Manganese sulphate is rarely employed in medicine at the present time. It was formerly prescribed internally as a remedy for anæmia, and in the form of an ointment applied externally to enlarged joints and glands. It may be tried in the treatment of malarial jaundice. The ordinary internal dose is from 1 to 3 grains (0.05–0.20 Gm.).

MANGANUM.—Manganese.

Manganèse, Fr.; *Mangan*, G.

Symbol, Mn. Atomic weight, 54.6.

Manganese in combination occurs in small quantity in many mineral waters and in ashes of plants and animal substances. It frequently accompanies iron in its ores, but it occurs chiefly as the dioxide or black oxide. It is found to some extent also in the form of other oxides in the minerals *braunite*, *manganite*, and *hausmannite*, and as carbonate. The black oxide and similar minerals of manganese were looked upon by the older chemists as belonging to the iron ores, but Scheele proved (1774) that these contained a new metal, which was isolated by Gahn in 1807. The metal is difficult to obtain by the older process of reduction of the oxide by charcoal at intense heat, but it is now obtained comparatively easily by Goldschmidt's method, namely, reduction of an oxide (Mn_3O_4) by powdered aluminum. The metal is grayish-white with a reddish sheen, and sufficiently hard to scratch glass and steel; it is more brittle and melts at a higher temperature than iron (1900° C.), and has the specific gravity 8. It is easily attacked by acids. Of practical value in the steel industry are the alloys of iron and manganese, namely, spiegeleisen, containing 10–20 per cent. of manganese, and ferromanganese, containing 20–80 per cent. of manganese.

Manganese has a variable valence and forms a number of oxides: *Manganous oxide*, MnO, gives rise to the manganous salts, which are the stable combinations of manganese. *Manganic oxide*, Mn_2O_3, found in nature as the mineral braunite, gives rise to the man-

ganic salts, which are unstable and easily converted into the manganous salts. *Manganoso-manganic oxide*, Mn_3O_4, is found as the mineral hausmannite, and is formed when any of the other oxides are highly heated. *Pyrolusite*, or the dioxide, MnO_2, is official. *Manganese trioxide*, MnO_3, is a dark-red liquid volatile at 50° C. (122° F.). *Manganese heptoxide*, Mn_2O_7, is a greenish-black thick liquid, volatile between 60° and 70° C. (140° and 158° F.), and very explosive. These last two oxides have acid properties, and give rise to manganic and permanganic acid, respectively, H_2MnO_4 and $HMnO_4$. The latter exists in the free state, but the former exists only in its salts.

Conclusive tests for the presence of manganese, even in very small quantities are: 1, the dark-green mass obtained by fusion with sodium carbonate and potassium nitrate or chlorate (salt of manganic acid); 2, the red color of permanganic acid when a trace of manganese is treated with red lead oxide and moderately strong nitric acid; 3, the violet color imparted to a borax bead.

SALTS OF MANGANESE.

Mangani Carbonas. *Manganese carbonate*, E.; *Mangankarbonat*, G. $MnCO_3$.—It is prepared by precipitating in the presence of a little syrup a solution of manganous sulphate with sodium carbonate, washing the precipitate well, and drying it rapidly at a moderate heat. It is a white powder, having a brownish tinge and dissolving in carbonic acid water, leaving a slight residue of brown manganic oxide. It has been recommended in the treatment of anæmia, and is said to increase the quantity and improve the character of the blood. Dose, from 10 to 30 grains (0.60–1 Gm.), daily, in pill-form.

Mangani Chloridum. *Manganese chloride*, E.; *Manganchlorür*, G. $MnCl_2.4H_2O$.—Manganese chloride is most economically obtained by evaporating the liquor obtained in the preparation of chlorine to get rid of free acid, dissolving the residue in water and digesting with manganous carbonate until the iron has been completely precipitated; the filtrate is evaporated, crystallized, and by recrystallization purified from calcium chloride if present. The salt is in granular, or when slowly evaporated in tabular, crystals of a pale rose-red color. It is soluble in alcohol, and requires at ordinary temperature about 2½ parts of water for solution. It has been employed locally as a stimulant to syphilitic and other indolent ulcers.

Mangani Iodidum. *Manganese iodide*, E.; *Manganjodür*, G. MnI_2.—Manganese iodide is a very deliquescent salt, and is best administered in the form of *syrup*, which may be prepared by dissolving manganese carbonate in hydriodic acid, or by the following formula proposed by Procter (1850): Take of manganese sulphate, 16 drachms; potassium iodide, 19 drachms; sugar, water, of each a sufficient quantity. Dissolve each of the salts in 3 fluidounces of water containing 2 drachms of syrup; mix, and after precipitation filter the solution into a bottle containing 12 ounces of sugar; add water to make a pint, and shake the bottle till the sugar is dissolved. Each fluidounce contains 1 drachm of manganese iodide; it may be given in doses of 10 drops to ½ fluidrachm (0.7–4 Gm.). Procter also proposed a *syrup of the iodides of iron and manganese*, to be prepared as follows: Take of potassium iodide, 1000 grains; ferrous sulphate, 630 grains; manganese sulphate, 210 grains; clean iron filings, 100 grains; powdered sugar, 4800 grains; distilled water, sufficient. Rub the sulphates and iodide separately to powder, mix with the iron filings, add ½ fluidounce of water, and rub to a uniform paste; add the same quantity of water a second and a third time at intervals of 15 minutes, and rub. Place the sugar in a bottle, and drain the dense solution into it through a filter, adding water slowly to the magma until the solution of the iodides is displaced and the liquid measures 12 fluidounces. Lastly, agitate the bottle till the sugar is dissolved. Each fluidounce contains 50 grains of the iodides in the proportion of 3 parts of ferrous iodide to 1 of manganous iodide. The dose is the same as the preceding. Both syrups contain potassium sulphate. It is employed for its alterative effect, and is thought to be especially useful in the treatment of anæmia dependent upon syphilis, tuberculosis, and cancer. Dose, 2 grains (0.10 Gm.), daily, in pill-form.

Mangani Lactas. *Manganese lactate*, E.; *Milchsaures Manganoxydul*, G. $Mn(C_3H_5O_3)_2.3H_2O$.—Manganese lactate is formed by adding manganese carbonate to hot lactic acid; on evaporating the filtrate the salt is obtained in pale rose-red shining crystals, which contain 19 per cent. of water of crystallization, are soluble in 12 parts of cold water, and dissolve likewise in hot alcohol, crystallizing again on cooling. Dose, from 1 to 5 grains (0.05–0.30 Gm.) daily.

Mangani Phosphas. *Manganese phosphate*, E.; *Manganphosphat*, G.—Manganese phosphate is obtained by precipitating 10 parts of manganese sulphate with 11 parts or sufficient of sodium phosphate, each separately dissolved in about 80 parts of water, washing the precipitate well to remove the sodium sulphate, and drying. It is a white crystalline powder, sometimes with a reddish tint, having the composition $Mn_3(PO_6)_2.4H_2O$, and dissolving

readily in dilute acids. It may be employed in the treatment of chlorosis in doses of from 1 to 5 grains (0.05–0.30 Gm.) daily.

Mangani Tannas. *Manganese tannate*, E.; *Mangantannat*, G.—Manganese tannate was recommended by Marletta (1865). It is obtained by adding recently precipitated manganese carbonate to a hot solution of tannic acid in distilled water until it ceases to dissolve, filtering, and evaporating to dryness. The carbonate must be absolutely free from iron, and the solution must be protected from contact with iron, otherwise it will acquire an inky color. The salt is soluble in water, and when prescribed in solution syrup or glycerin should be added for preservation.

Mangani Tartras. *Manganese tartrate*, E.; *Mangantartrat*, G.—On dissolving 10 parts of Rochelle Salt and 8 parts of manganese sulphate, each in its own weight of hot water, and mixing the solutions, small white or pale-reddish crystals of manganese tartrate are obtained on cooling, which must be washed with cold water, since hot water decomposes them into a soluble acid and an insoluble basic salt. Dose, 1 to 5 grains (0.065–0.32 Gm.) daily.

MANNA, *U. S., Br., P. G., P. A.*—Manna.

Manne, Fr. Cod.; *Manna*, G., Sp.

The concrete saccharine exudation of *Fraxinus Ornus* L. (*F. Ornus rotundifolia* L.; *F. Ornus Europæus* Pers.; *F. rotundifolia* Lam.—Fam. *Oleaceæ*).

Origin and Collection.—The *Manna* or *Flowering Ash* is a slender tree, of ornamental habit, native of the Mediterranean region and often cultivated, both for the production of manna and for ornament. Manna is produced by it chiefly, or perhaps wholly, in the northern part of Sicily. When the tree is about 8 years old and its trunk at least 75 Mm. (3 In.) in diameter, it will yield manna, and it remains productive for from 12 to 20 years, when the stem is cut down and replaced by a shoot from the stump. The incisions are made in dry weather with a hooked knife, one each day, commencing near the root and one directly above another; they are transverse, 5 Cm. (2 In.) or less in length, and penetrate through the bark to the wood. In the following year the same operation is repeated on the untouched side. The juice flowing from the lower incisions is collected on tiles or in receptacles made from the stem of an Opuntia; that from the upper incisions hardens on the stem, or, for producing a superior variety called *manna a cannolo*, which is rarely seen in commerce, is allowed to harden on sticks or straws inserted into the cuts. When sufficiently hard, the large pieces are gathered, and completely dried before being packed, while the smaller ones are afterward scraped from the stem and sold separately.

Description and Tests.—The varieties of manna generally distinguished in our commerce are *large flake*, *small flake*, and *sorts*. Flake manna (*Manna cannellata* or *electa*) consists of 3-edged pieces varying in length from 1 to 15 or 20 Cm. (½ In. to 6 or 8 In.), 1 to 5 Cm. (½ to 1 or 2 In.) wide, and somewhat less in thickness, flat or curved on one side where it adhered to the tree, and uneven from roundish projections on the others, showing the marks of different layers. It is externally of a yellowish-white, in some places pale-brownish color, friable, internally porous, and the cavities filled with white glistening crystals of mannit. Its odor is honey-like, somewhat nauseous, and its taste sweet, but combined with a very slight bitterness and acridity. Large and small flake manna differ only in size, the latter, however, being often of a dark shade. Small flake manna is often called *Manna in tears* (*in lachrymis*). Manna in sorts (*Manna communis*, *geracina*, *calabrina*, or *in sortis*) consists of the scrapings, and is met with in fragments from the size of a pin's head to about 12 Mm. (½ In.) in diameter, with a rather adhesive surface and of a brownish color outside, but internally nearly white and crystalline; not infrequently the fragments are united by a viscid brownish matter, which, without the flakes, constitutes *fat manna* (*Manna pinguis*, *crassa*, or *de Puglia*), a variety rarely seen in this country, and rejected by the pharmacopœias. It flows from the incisions late in autumn, and is more particularly yielded by old trees; it is soft and glutinous, entirely devoid of crystals, and less agreeable in odor and taste than flake manna, from which it differs in containing much less mannit and more gum, sugar, and coloring-matter.

The U. S. P. states that on boiling 5 parts of manna with 100 parts of alcohol, a solution should be obtained which does not affect the color of litmus, and while cooling deposits many crystals of mannite.

Different pharmacopœias limit the ash at from 1.3 to 4 per cent. Several specify that it should contain not more than 10 per cent. of water. The amount of mannite required by different pharmacopœias to be contained ranges from 70 to 80 per cent.

Composition.—The best dry-flake manna contains about 90 per cent. of *mannite* [$C_6H_8(OH)_6$], the remainder being fermentable sugar, mucilage, and resin. Manna of inferior quality contains cane-sugar, levulose, and bitter substances soluble in ether, and may have a greenish color due to *fraxin* ($C_{16}H_{18}O_{10}$), a fluorescent glucoside resembling æsculin, crystallizing in colorless prisms with faint, astringent, bitter taste, and easily soluble in hot water and alcohol. With dilute acids fraxin yields *fraxetin* ($C_{10}H_8O_5$) and glucose.

Mannite crystallizes from the boiling alcoholic solution of manna in colorless needles or glossy rhombic prisms. It dissolves in 6 parts of cold water, in much less hot water, and in 90 parts of 67 per cent. alcohol, and is insoluble in ether and nearly so in absolute alcohol. It sublimes at 200° C. (392° F.), when most of it is converted into *mannitan* ($C_6H_{12}O_5$), a sweetish, syrupy liquid. The solutions of mannit are not altered by boiling with dilute acids, do not reduce Fehling's Solution, and except under special conditions do not ferment. Nitric acid converts it into racemic acid and sugar, and ultimately into oxalic and saccharic acids. Moist platinum-black converts it into *mannitic acid* ($C_6H_{12}O_7$) and *mannitose* ($C_6H_{12}O_6$), a fermentable sugar.

Pharmaceutical Preparation.—Syrup of Manna, N. F.

Action and Uses.—Manna usually operates as a gentle laxative, but in some persons produces flatulent colic. When given to adults it is usually combined with more energetic remedies, such as rhubarb, senna, and magnesia, as it disguises their taste and aids in their laxative effect. It may also be added to the milk of bottle-fed infants suffering with obstinate constipation. The dose for an infant is from 1 to 2 drachms (4–8 Gm.), for an adult from 1 to 2 ounces (30–60 Gm.).

Other Mannas.—The number of saccharine exudations to which the name Manna has been applied, is very large. That sometimes obtained in southern Europe from incisions into the trunk of *Fraxinus excelsior* L. is identical with the kind above described. *Briançon manna* is a whitish exudation from the European birch, and contains the sugar *melezitose* ($C_{12}H_{22}O_{11}.3H_2O$). The leaves of *Eucalyptus viminalis* Lab., *E. Gunnii*, and of other Australian species of *Eucalyptus*, yield *Australian manna* containing *melitrose*, a condensation-product of equal molecules of galactose, glucose, and fructose. Baker and Smith report upon another kind of Australian manna, called *Blue-grass manna*, which exudes from the stems of *Andropogon annulatus* (Forsk.?), concreting in masses as large as marbles, and containing 75 per cent. of mannit, together with a ferment which decomposes cane-sugar without the evolution of CO_2 or other gas. A *Californian manna* is collected by the Indians of that State from the stems of *Phragmites communis* Trin. In Oregon, a kind of manna is collected from *Pinus Lambertiana* Dougl. *Bamboo manna* is the name applied in India to an exudation very similar to cane-sugar, from the stems of *Dendrocalamus strictus* Nees. It exudes rarely, but then in great abundance. About 95 per cent. of it is a sugar which becomes inverted in 20 minutes when boiled with a 1 per cent. solution of hydrochloric acid. *Persian manna* comes from *Alhagi Camelorum* Fisch. (Fam. *Leguminosæ*), and contains spines and leaflets of the plant; other varieties are produced by *Salix fragilis* L., and different species of *Astragalus*. *Tamarisk manna* exudes from *Tamarix mannifera* Ehrh. in consequence of a puncture made by an insect, *Coccus manniparus* Ehrh., and is collected near Mount Sinai, and sold by the monks of the convent of St. Catharine; it contains cane-sugar, glucose, and dextrin. *Armenian* (*oak*) *manna* results from the puncture of a coccus upon the leaves of *Quercus Vallonea* Kotschy, and *Q. persica* Jaubert et Spach; it is either dissolved from the leaves by water, which is then evaporated, or else scraped off, and then is mixed with numerous small fragments of the leaves; it consists chiefly of grape-sugar. *Lebanon manna* is in small sweet grains obtained from *Cedrus libanotica* Link. Saccharine exudations have been observed upon the larch and a number of other plants, and the saccharine products of some insects, like the *trehala* (*tigala*) of Syria, containing the peculiar sugar *trehalose*, and the *lerp* of Australia, have sometimes been classed with the mannas; they are not entirely soluble in water.

MARRUBIUM.—Hoarhound; Horehound.

Herba marrubii.—Herbe de marrube blanc, Fr. Cod.; *Andornkraut, Weisser Andorn*, G.; *Marrubia*, Sp.; *Marroio branco*, Port.

The dried leaves and tops of *Marrubium vulgare* L. (Fam. *Labiatæ*).

Marrubium was official in the U. S. P. of 1890 and previously, and is official in a number of European pharmacopœias. The Spanish requires the flowering herb. The Portuguese specifies the leaves only and that they be from *M. hamatum* Kunth.

Origin.—Hoarhound is a perennial herb with numerous weak stems, the basal portions mostly prostrate. It is native of Europe and Asia, largely cultivated as an aromatic, in gardens, and naturalized in most temperate and subtropical regions.

Fig. 267.

A, *Marrubium vulgare* (Nat.); a, calyx (×3). B, spurious marrubium (Nat.); b, calyx (×3).

Description.—Leaves opposite, exstipulate, shortly and broadly petioled, the blades 2 to 4 Cm. (1 to 1½ In.) long, roundish-ovate, truncate or subcordate at the base, obtuse, strongly rugose-veiny, more or less white-hairy, especially underneath; stems quadrangular, densely white-hairy; flowers in dense, axillary, white-woolly whorls; calyx tubular, 5- to 10-nerved, with 10 almost equal, erect-spreading, pungent teeth; corolla whitish, bilabiate; stamens didynamous; fruit of 4 ovoid, obtuse, smooth nutlets, 1 to 2 Mm. long and about half as broad; aromatic and bitter.

A spurious Marrubium is sometimes sold, having leaves of about half the size, thinner, less rugose, and 5 of the calyx-teeth much smaller or wanting.

Constituents.—Hoarhound contains about 0.02 per cent. (Harms) or about 4 per cent. (Matuson) of the amaroid marrubiin, two other bitter bodies, tannin, a trace of volatile oil, fat, wax, resin, gum, and pectin. *Marrubiin* ($C_{30}H_{43}O_6$) forms bitter, somewhat acrid, prismatic or tabular crystals, slightly soluble in water, and not precipitated by tannin. It melts at 154° to 155° C. (309.2° to 311° F.). It is neither a glucoside nor an aldehyde.

Action and Uses.—Horehound may be employed as an expectorant, diaphoretic, and in large doses as a laxative. In the form of candy or syrup it is largely used by the laity in the treatment of chronic bronchial affections, and an infusion (1 ounce [30 Gm.] to 1 pint [480 Cc.]) is likewise thought to be beneficial as a remedy for chronic rheumatism and menstrual disorders. It has also been recommended in the treatment of chronic hepatitis and jaundice. The dose of the infusion is about 4 fluidounces (120 Cc.).

MASSA COPAIBÆ.—Mass of Copaiba.

Pilulæ copaibæ.—Solidified copaiba, E.; *Masse pilulaire de copahu*, Fr.; *Copaiva-Pillenmasse*, G.

Mass of Copaiba is no longer officially recognized.

Preparation.—The U. S. P., 1890, gave the following directions: Copaiba, 94 Gm.; magnesia, 6 Gm.; water, a sufficient quantity. Upon the magnesia, contained in an enamelled iron capsule, sprinkle a sufficient quantity of water to make it distinctly damp, and render it homogeneous by trituration. Then gradually incorporate with it the copaiba, so that a uniform mixture may result, place the capsule on a water-bath and heat during half an hour, frequently stirring. Lastly, transfer the mixture to a suitable vessel and set this aside until the mass has acquired a pilular consistence.

The directions to sprinkle the magnesia with water are for the purpose of properly hydrating the same, as it is well known that anhydrous magnesia does not readily combine with the acid resin. The combination may be looked upon as magnesium copaivate with volatile oil of copaiba.

The variety of copaiba best adapted for this mass is Maracaibo copaiba, since it contains a larger proportion of resin; this enters into combination with the magnesia, forming a resin soap, which gradually becomes dry and hard. If thin Para copaiba is to be used, it is advisable to evaporate sufficient of the volatile oil until the residue, after cooling, forms a viscid liquid, when it may be mixed with the magnesia.

In Europe pills of copaiba and powdered cubebs are sometimes used, and made into a mass by means of wax. The quantities necessary are 1 part of each of the ingredients named, or 3 parts of copaiba, 5 of cubebs, and 1 of wax. This mass retains its plasticity for a long time.

Action and Uses.—This preparation forms a convenient method for the administration of copaiba in pill-form. When administered in this manner, the efficacy of the copaiba is probably decreased. It should be administered in 5-grain (0.30 Gm.) pills, of which from 2 to 6 may be taken 2 or 3 times daily.

MASSA FERRI CARBONATIS, *U. S.*—Mass of Ferrous Carbonate.

Pilula ferri carbonatis, Br.—*Vallet's Mass, Vallet's pill mass*, E.; *Masse pilulaire de Vallet, de carbonate ferreux*, Fr.; *Valletsche, Pillenmasse*, G.

Preparation.—Ferrous sulphate, in clear crystals, 100 Gm.; monohydrated sodium carbonate, 46 Gm.; clarified honey, 38 Gm.; sugar, in coarse powder, 25 Gm.; syrup, distilled water, each a sufficient quantity to make 100 Gm. Dissolve the ferrous sulphate and the monohydrated sodium carbonate, each separately, in 200 Cc. of boiling distilled water, and, having added 20 Cc. of syrup to the solution of iron salt, filter both solutions, and allow them to become cold. Introduce the solution of monohydrated sodium carbonate into a bottle having a capacity of about 500 Cc., and gradually add the solution of the iron salt, rotating the bottle constantly or frequently until carbon dioxide no longer escapes. Add a sufficient quantity of distilled water to fill the bottle; then cork the bottle and set it aside, so that the ferrous carbonate may subside. Pour off the supernatant liquid, and, having mixed syrup and distilled water in the proportion of 1 volume of syrup to 19 volumes of distilled water, wash the precipitate with the mixture by decantation until the washings no longer have a saline taste. Drain the precipitate on a muslin strainer, and express as much of the water as possible. Lastly, mix the precipitate at once with the honey and sugar, and, by means of a water-bath, evaporate the mixture in a tared capsule, with constant stirring, until it is reduced to 100 Gm.—U. S.

To make 4 avoirdupois ounces of Vallet's Mass will require the following quantities: ferrous sulphate, crystals, 4 avoirdupois ounces; monohydrated sodium carbonate, 805 grains; clarified honey, 665 grains; sugar, in coarse powder, 438 grains.

On mixing solutions of ferrous sulphate and sodium carbonate, ferrous carbonate and sodium sulphate are formed by mutual decomposition. In contact with air the white iron precipitate rapidly oxidizes. The change is prevented by washing the precipitate in bottles by decantation with water recently boiled, and excluding the air; an additional protection is afforded by dissolving some sugar in the water. The pill mass, when recently made, is of a greenish-gray color, but on exposure becomes superficially greenish-black.

The quantity of ferrous sulphate ordered in the official formula is capable of yielding very nearly 42 Gm. of ferrous carbonate, but as some of the precipitate is lost by washing, and as the weight of the finished product is directed to be brought to 100 Gm., scarcely more than 35 or 36 Gm. of ferrous carbonate will be present, equal to 35 or 36 per cent.

The formula of the French Codex is almost identical with that of the United States Pharmacopœia, except that milk-sugar is used in place of sugar; 3 parts of the mass are mixed with 1 part of powdered licorice-root, and divided into pills, each weighing 0.25 Gm., which are to be silvered.

Action and Uses.—Because of its freedom from astringency, this preparation is less liable to produce dyspeptic disorders than the other preparations of iron. Vallet's mass is largely employed in the treatment of simple anæmia and chlorosis, and is probably the most effective preparation of iron we have for the treatment of the latter condition. The ordinary dose is from 3 to 5 grains (0.20–0.30 Gm.), 3 times daily.

MASSA HYDRARGYRI, *U. S.*—Mass of Mercury.

Pilula hydrargyri, Br.; *Massa cærulea.—Blue mass, Blue pill*, E.; *Masse pilulaire bleue*, Fr.; *Mercurialpillenmasse*, G.

Preparation.—Mercury, 33 Gm.; glycyrrhiza, in No. 60 powder, 10 Gm.; althæa, in No. 60 powder, 15 Gm.; glycerin, 9 Gm.; honey of rose, 33 Gm.; to make 100 Gm. Triturate the mercury with the honey of rose until it is extinguished, and globules of mercury are no longer visible under a lens magnifying at least 10 diameters. Then add the glycerin, then the glycyrrhiza and althæa, and continue the trituration until the mass is homogeneous. Keep the product in well-closed containers.—U. S.

To prepare 4 avoirdupois ounces of blue mass will require 578 grains of mercury, 174 grains of glycyrrhiza, 261 grains of althæa, 159 grains of glycerin, and 578 grains of honey of rose.

Mercury, 2 parts; confection of roses, 3 parts; licorice-root, in fine powder, 1 part. —Br., Fr. Cod.

The British Pharmacopœia still directs the mercury to be extinguished by trituration with confection of roses, and the U. S. Pharmacopœia recommends trituration with a saccharine liquid (honey), which facilitates division of the metal.

The U. S. P. prescribes the following tests: If a portion of the mass be triturated in a mortar, with warm acetic acid, the filtrate should not become more than slightly opalescent on the addition of a few drops of hydrochloric acid (limit of mercurous oxide). If another portion of the mass be digested with warm diluted hydrochloric acid and a little purified animal charcoal, the filtrate should not be affected by hydrogen sulphide test-solution nor by stannous chloride test-solution (absence of mercuric oxide).

When properly prepared, blue mass contains metallic mercury in the state of very fine division. It is not impossible that when kept on hand for a long time a change, due to the partial oxidation of mercury, may gradually take place, as has been repeatedly observed. Such a change, however, could only be very superficial, since the metal is well protected by the other ingredients of the pill mass.

Pulvis Massæ Hydrargyri, Æthiops Saccharatus.—*Powdered blue mass*, E.; *Poudre de mercure saccharin, Mercure (Ethiops) saccharin*, Fr.; *Wurmzucker*, G.—Blue mass, or blue pill, is not infrequently ordered in powders, but is unsuited for the purpose unless mixed with other absorbent powders. It may, however, be readily obtained in the state of a permanent powder having the same relative composition as the pill mass by substituting in the above directions for the glycerin and honey of rose an equal weight of milk-sugar, using a drop of oil of roses to impart the requisite flavor, and keeping the mixture moist by the addition of alcohol; after a uniform mass has been obtained it is spread out to allow the alcohol to evaporate spontaneously, after which it may be reduced to a permanent powder. W. E. Bibby (1876) recommended 1 part of mercury to be triturated with 2 parts of sugar of milk, without adding any liquid, the metal being rapidly extinguished.

Pilulæ cum Hydrargyro, Pilules Mercurielles Simples, Fr. Cod.—*Blue pills*, E.; *Pilules de mercure, Pilules bleues*, Fr.; *Mercurialpillen*, G.—Each pill contains $\frac{3}{4}$ grain. (0.5 Gm.) of mercury, Fr. Cod.

Action and Uses.—Massa hydrargyri is rarely employed at the present time for its systemic effect. Given in doses of from 3 to 5 grains (0.20–0.30 Gm.) it is said to increase biliary secretion and produce purgative effects analogous to those of Calomel (which see). If employed for its systemic effect, it should be given in divided doses, $\frac{1}{4}$–$\frac{1}{2}$ grain (0.015–0.03 Gm.), repeated every 2 hours. If given in this manner, absorption occurs, and intestinal irritation is to some extent avoided.

MASTICHE, *U. S., P. A.*—Mastic; Mastich.

Resina pistaciæ, Ph. Nor.; *R. mastiche, mastix*, G.; *Mastic*, Fr.; *Almaciga*, Sp.; *Mastica, Almecega da India*, Port.

A concrete resinous exudation from *Pistacia Lentiscus* L. (*P. L. Chia* Duham.) (Fam. *Anacardiaceæ*).

Origin and Collection.—The mastic plant is a large shrub or small tree of the Mediterranean region, particularly abundant on the Island of Scio or Chio, in the Grecian Archipelago, where most of the resin is collected. The resin is contained in the bast-layer of the bark, in elongated ducts having a large elliptic cavity and surrounded by one or more layers of small cells, in which the resin is secreted. To obtain it, vertical incisions are made in June and July in the bark of the trunk and larger branches, and in July and August, after the exuding resin has hardened, it is carefully removed from the tree and collected in baskets; this is the finest quality. An inferior quality consists of the tears which have dropped from the incisions upon tiles or flat stones kept under a tree. A vigorous tree may yield 10 pounds of mastic. The chewing of mastic, especially by women, is very general in the country of its production, and a large part of the crop is consumed in this way.

Description.—In more or less globular, flattened or elongated tears about as large as peas, the surface free from dust, or nearly so, smooth, and lustrous, varying from a pale to a rather deep-yellow, transparent, and of an opalescent refraction, brittle when cold, the fracture conchoidal; becoming readily plastic when chewed; softening below the boiling-point of water and fusing at a few degrees above it; specific gravity, about 1.07; odor balsamic, especially when heated; taste terebinthinous; soluble in ether, benzene, acetone, volatile oils, cold creosote and warm petroleum, and partly soluble in alcohol, the last-named solution reddening litmus. The acid number should not be less than 65.

Mastiche loses greatly in plasticity upon being kept, and its color at the same time deepens. In inferior grades, sand and fragments of bark adhere to the tears, many of which are gray or brown.

Constituents.—The volatile oil of mastiche varies in amount from 1 to 2.5 per cent. It has a powerfully balsamic odor, similar to that of the drug, is clear, of a pale-yellow color, and has a specific gravity of about 0.858. Its important constituent is d-pinene. The remainder of mastiche consists of two resins, about 90 per cent. *alpha-resin* or *mastichic acid*, which is soluble in alcohol, combines with bases, and has the composition $C_{20}H_{32}O_2$. The rest is *beta-resin* or *masticin*, which is white and tenacious, insoluble in alcohol, soluble in ether and oil of turpentine, and has a composition of $C_{20}H_{31}O_2$. There is a very small amount of a bitter principle which is dissolved by hot water, to which it imparts an acid reaction, and which is precipitated by tannin.

Pharmaceutical Preparation.—Pills of Aloes and Mastiche, U. S. P.

Action and Uses.—Mastiche is rarely employed in medicine in this country, except in the form of Pilulæ Aloes et Mastiche. It was formerly employed in the treatment of catarrh of the bronchial and urinary tracts, in leucorrhœa, gastric debility, and chronic diarrhœa. A solution in alcohol may be applied with a camel's-hair brush as a styptic in epistaxis, leech-bites, and other small wounds. Dissolved in one-fourth its weight of ether mastiche has been recommended as a temporary filling for carious teeth.

Substitutes and Related Products.—*Bombay mastiche* closely resembles the official, but is generally of a darker color and a less agreeable odor. Usually, it is less clear and transparent. Its botanical origin is somewhat in doubt, but is believed to be *P. mutica* F. et M. (*P. cabulica* Stokes) and *P. khinjuk* Stokes. *Barbary mastiche, Roman mastiche,* or *Mustagi Rumi,* is similar and is from *P. Atlantica* Desf.

Astronium Urundeuva (All.) Eng. (*Myracrodendron U.* All.), of the same family, yields, in Brazil, a mastiche-like resin, which is used in varnishes.

Acantho-mastiche or *Pseudomastiche* is a Grecian product of *Atractylos gummifers* L. (Fam. *Compositæ*).

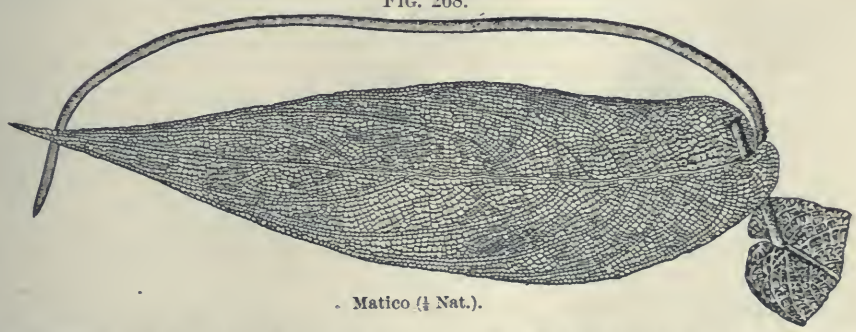
MATICO, *U. S., Fr. Cod.*—Matico.

Feuilles de matico, Fr.; *Maticoblätter,* G.; *Yerba del soldado,* Sp.

The dried leaves of *Piper angustifolium* R. et P. (*P. elongatum* Vahl.; *Artanthe e.* Miq.; *Steffensia e.* Kunth.—Fam. *Piperaceæ*).

Matico is still official in several pharmacopœias, and was so until recently in the British. The plant is a large soft-wooded shrub or very small tree of the Andes of Peru and Bolivia. The plants so-called from Brazil, Mexico, and other sections are of different species.

Fig. 268.



Matico (½ Nat.).

Description.—From 12 to 20 Cm. (5 to 8 In.) long; and 2.5 to 5 Cm. (1 to 2 In.) broad, subsessile, lanceolate, very unequal and lightly cordate at the base, long-tapering and acute, very finely crenulate, thickish and brittle, dark-green, scabrous, and very finely and regularly bullate above, grayish- or yellowish-gray-green, short-hairy and lacunate underneath; aromatic, pungent, bitter, and somewhat astringent.

The axillary flower-spikes, sometimes present, are very slender and longer than their leaves.

Constituents.—The important constituents of Matico are its tannin, volatile oil, and bitter principle, with which occur a ruby-red, pungent, and acrid resin, and crystalline *artanthic acid.* The volatile oil exists to the extent of 2 or 3 per cent., varies in color from yellow to brown, and has a specific gravity of about 0.930. Upon being cooled, crystals of *matico camphor* ($C_{12}H_{20}O$) separate from it. Its active properties are apparently due to the presence of this stearopten.

Pharmaceutical Preparations.—Fluidextract of Matico, U. S. P.

Action and Uses.—Matico possesses the properties of an aromatic, stimulant, tonic, and diuretic. It may be employed in the treatment of subacute and chronic bronchial affections, catarrhal and specific inflammations of the urinary tract, chronic diarrhœa, and in hemorrhage from the lungs, kidneys, and gastro-intestinal tract. When locally employed, it acts as a styptic, but this action is probably mechanical. Matico is said to be used locally by the natives as a vulnerary, and to be taken internally by them for its aphrodisiac properties. The dose of the powdered leaves is from ½ to 2 drachms (2–8 Gm.).

Other Maticos.—A number of astringent and hæmostatic leaves are known in tropical America as "maticos." Several of these are from species of Piper, and have appeared in commerce for Matico, especially those from *P. aduncum* L. (*Artanthe a.* Miq.). Their form is somewhat similar, but the summit is not nearly so tapering. The upper surface is marked by some sunken, ascending, and parallel nerves, and the lower surface by corresponding reticulations, but they have not the tessellated appearance nor the roughness and hairiness on the lower surface observed on the official matico leaves; their properties appear to be the same. The flower-stalks are much shorter than the leaves from the axils of which they arise.

Other leaves to which the name has been applied are those of *Eupatorium glutinosum* Kunth (Fam. *Compositæ*) and *Waltheria glomerata* Presl. (Fam. *Sterculiaceæ*).

MATRICARIA, *U. S.*—Matricaria; German Chamomile.

Flores chamomillæ, P. G.; *Flores chamomillæ vulgaris; Wild chamomile, Horse gowan, Dog's chamovyne*, E.; *Kamille, Kamillenblumen*, G.; *Camomille commune (d'Allemagne)*, Fr. Cod.; *Manzanilla comun, de Aragon*, or *de Alemania*, Sp.; *Flori di Camomilla Comune*, It.; *Camomilla dos Allemaes*, Port.

The dried flower-heads of *Matricaria Chamomilla* L. (*Chrysanthemum C.* Bernh.; *Chamomilla vulgaris* S. Gray; *C. officinalis* Koch.—Fam. *Compositæ*).

Matricaria is official in nearly all pharmacopœias. Many of them require the rejection of certain named species which resemble the official. The same result is attained by the German for all such species, by requiring the rejection of all similar flower-heads having a solid and chaffy receptacle.

Fig. 269.

Matricaria: *a*, flower-head; *b*, involucre; *c*, receptacle and involucre; *d*, longitudinal section of receptacle, with disk-florets; *e*, ray-floret; *f*, disk-floret; *g*, stamens and style of disk-floret.

Origin.—The matricaria plant is a smooth, slender, branching annual with elongated and slender stems and branches, mostly decumbent at the base, the leaves twice to thrice

pinnatifid with sebaceous, spreading segments. It is native and abundant in temperate Europe and Asia, and is naturalized in most similar regions. It is a common roadside weed in many parts of the United States, its white flowers appearing in late spring and through the summer. The drug loses 75 to 80 per cent. in drying.

Description.—About 6 to 8 Mm. (¼ to ⅓ In.) broad, exclusive of the rays; involucre flattish, closely imbricated; rays about 15, 1-serialled, reflexed, ligulate, white, about 8 Mm. (⅓ In.) long; disk yellow, hemispherical, of very numerous tubular, perfect flowers, without pappus; receptacle conical, naked, hollow; odor mild, pleasant; taste strongly aromatic and bitter.

The similar flower-heads of *Anthemis arvensis* L., and *Maruta Cotula* De Candolle (Fam. *Compositæ*), which are sometimes substituted, and which have similar properties, have conical, solid, and chaffy receptacles.

Constituents.—German chamomile flowers contain about ¼ per cent. of volatile oil, some bitter extractive, malates, tannates, and a little tannin, besides the principles common to vegetables. Pattone's *anthemic acid*, isolated (1859) from *Anthemis arvensis* L., was obtained by Werner (1867) from the official flowers by exhausting them with hot water acidulated with acetic acid, concentrating, precipitating with alcohol, evaporating the filtrate, and treating with chloroform. It is described as in colorless silky needles having an agreeable odor of chamomile, a strongly bitter taste, and dissolving in water, alcohol, ether, and chloroform. The precipitate obtained with alcohol is stated to contain a tasteless crystalline principle, *anthemidin*, which is insoluble in alcohol, ether, and chloroform, but soluble in acetic acid. Doubts were expressed by Flückiger as to the existence of anthemic acid and anthemidin in Matricaria.

Oil of German chamomile is a somewhat viscid fluid of intense blue color, having at 15° C. (59° F.) a specific gravity of 0.930–0.940. It is soluble in 8 parts of 90 per cent. alcohol. Upon exposure to light and air, it gradually changes in color to green and finally to brown. At 0° C. (32° F.) it increases in viscidity, and upon still further reduction of temperature assumes the consistence of butter. Subjected to fractional distillation, it yields at 150° to 165° C. (302°–327° F.) a colorless oil possessing a strong odor of the flowers, and another colorless fraction at 250° C. (482° F.). The azure-blue constituent, known as azulene, passes over between 270° to 300° C. (518°–572° F.), and is identical with the blue constituent of the oils of absinthe, sumbul, valerian, yarrow, etc.

Action and Uses.—Matricaria is rarely prescribed in this country except by German practitioners. It possesses mild tonic properties, and in large doses acts as an emetic and anthelmintic. It may be substituted for ANTHEMIS (which see).

MEL, *U. S., Br.*—Honey.

Miel, Fr. Cod.; *Honig*, G.; *Miel*, Sp.

A saccharine secretion deposited in the honeycomb by *Apis mellifica* L., the hive bee (Class, *Insecta;* Order, *Hymenoptera*).

Honey is official in nearly all pharmacopœias and is by them variously named as *Mel crudum*, *M. communis*, *M. naturale*, *M. album*, and *M. flavum*.

Properties.—When recently prepared, honey is a translucent or nearly transparent, pale-yellowish or brownish, thick, syrupy liquid, which, on keeping, separates a granular deposit, and is ultimately changed into a crystalline mass intermixed with some liquid. It is stated that California honey gathered in May becomes granular in a few days, but if taken later in the season remains liquid for a long time. It has a slight acid reaction, an agreeable odor, varying more or less from causes mentioned above, and a sweet taste, followed by a slight acridity. E. Dieterich (1877) ascertained that by dialyzing honey into water the dialyzed portion, on concentration, had a golden-yellow color and a remarkably fine floral odor, while the residue upon the dialyzer was destitute of honey odor and had a sweet but insipid taste.

Honey dissolves readily in water, also in diluted alcohol, yielding in both cases slightly turbid solutions which have a faint acid reaction. A mixture of honey with 2 parts of water should have a specific gravity not lower than 1.099 (U. S.), which corresponds to a specific gravity of 1.370 for the original honey.

By other pharmacopœias, the specific gravity is variously stated from 1.100 to 1.419. The Swiss and Russian mention that it should not change color upon the addition of an equal weight of ammonia.

Constituents.—The odor of honey is doubtless due to a minute quantity of volatile oil, which, according to Calloud, is intimately associated with a yellow coloring-matter, *melichroin*, separated by the nectaries and bleached on exposure to sunlight. Small quantities of wax and gummy matter are usually present, and A. Vogel (1882) found in crude honey about 0.1 per cent. of formic acid, which appears to preserve it from decomposition; but the main constituents are *grape-sugar* or *dextrose* and *fruit-sugar* or *levulose*, of each of which from 32 to 42 per cent., or a total of about 72 to 78 or 80 per cent., is present. The honey of an American wasp, *Polybia apicipennis* Sauss., according to Karsten (1857), contains cane-sugar, and the same may be the case with honey from other sources; this constituent, however, is gradually changed to *invert-sugar*, which is a mixture of grape- and fruit-sugars. It is the grape-sugar which renders honey granular, while the fruit-sugar remains liquid; the former turns polarized light to the right, the latter to the left. The albuminates, mucilaginous matter, pollen, and wax present in honey vary between about 0.5 and 1 or 2 per cent.; the ash left on incineration is generally between 0.12 and 0.16 per cent., and, according to Hager, should not exceed 0.5 per cent.

Adulterations.—The coarse adulteration with starchy substances is easily recognized in the soluble matter left on treating with alcohol, and by the blue color produced on the addition of solution of iodine. Adulterations with artificial grape-sugar prepared from starch by boiling with sulphuric acid are difficult to establish; aside from the physical properties, the presence of soluble sulphate (of calcium) affords the best criterion. Beet-root molasses contains chlorides, and if used for adulterating honey causes a white precipitate with silver nitrate. Starch paste, added with the view of rendering honey thick, is deposited as a jelly-like, stringy mass on dilution with water. Neither crude honey nor honey clarified by the process of the U. S. P. yields with water an absolutely clear solution. The tests given by the pharmacopœias are as follows: If 1 part of honey be dissolved in 4 parts of water, a clear solution should result, which should not be rendered more than faintly opalescent by a few drops of test-solution of silver nitrate (limit of chlorides) or of barium chloride (limit of sulphates). If 2 Cc. of a filtered solution of the honey (1 in 4) be placed in a test-tube 1 Cm. in diameter, and 1 Cc. of absolute alcohol be allowed to flow down the walls of the tube held in an inclined position, so as to form an overlaying layer, this should remain clear, and the line of contact should not show more than barely noticeable opalescence, which soon disappears; a permanent milky zone should not be produced (proof of purity and absence of starch sugar). If 2 Cc. of pure concentrated sulphuric acid be placed in a test-tube of 1 Cm. diameter, and 0.5 Cc. of a solution of honey (1 in 4) be allowed to flow upon it so as to form a distinct upper layer, no colored line of contact should show at once, and at the end of one hour the zone of contact should be at most yellowish or clear brown; a brownish color, becoming nearly black at the end of half an hour, should not develop (absence of cane sugar). When incinerated in small portions at a time in a platinum crucible, it should not leave more than 0.3 per cent. of ash. Water boiled with honey and allowed to cool should not be rendered blue or green on the addition of test-solution of iodine (absence of starch).—U. S.

Action and Uses.—Honey may be employed in medicine for the same purposes as syrup. It is employed principally as a vehicle, but its addition to mouth-washes and gargles increases the secretion of the mucous membranes and relieves congestion. It is useful in aphthæ, ulcerative stomatitis, and pharyngitis.

Special Varieties.—The honey produced in different parts of the world, by the species of bee yielding the official, as well as that produced by others, differs considerably in sensible properties, though but little in its general composition. The same is also true of honey produced in the same locality, at different seasons, and the difference is believed to be chiefly due to variation in the food of the bees; hence the terms "clover-honey," "buckwheat-honey," etc., the animals feeding almost wholly upon one plant while it is obtainable. Both isolated and epidemic cases of poisoning by honey have occurred, and these have also been attributed to poisonous substances having been fed upon by the bees. In some parts of Africa a brown, and even greenish, honey has been observed, which may be produced by different species of *Apis*.

Some years since, excitement was created by the announcement of the discovery of an Australian product (*Eucalyptus honey*) gathered in the Eucalyptus forests, made by the bees while feeding upon this tree, and possessing the supposed medicinal properties of the latter. Such a honey does exist, and its flavor is doubtless determined to some extent by the above-mentioned cause, but it possesses no special properties.

MEL BORACIS, *Br.*—Borax Honey.

Mel sodii boratis.—Honey of sodium borate, E.; *Mellite de borax, Miel boraté,* Fr.; *Boraxhonig,* G.

Preparation.—Take of borax, in fine powder, 1 ounce; glycerin, ½ ounce; clarified honey, 8 ounces. Mix.—Br.

Uses.—It is made extemporaneously, and is applied to most of the local affections enumerated in the article on HONEY.

MEL DEPURATUM, *U. S., Br., P. G.*—Clarified Honey.

Mel despumatum.—Miel despumé, Mellite simple, Sirop de miel, Fr.; *Gereinigter Honig,* G.

Preparation.—Honey, a convenient quantity; glycerin, a sufficient quantity. Mix the honey intimately with 2 per cent. of its weight of paper-pulp, which has been previously reduced to shreds, thoroughly washed and soaked in water and then strongly expressed and again shredded. Then apply the heat of a water-bath, and, as long as scum rises to the surface, carefully remove this. Finally, strain and mix the strained liquid with 5 per cent. of its weight of glycerin—U. S.

The object of clarification is to remove the wax and other impurities of honey, which rise to the surface when the honey is kept for a while in the condition of a thin fluid by exposing it to the heat of a water-bath; in the above process the impurities are more effectually removed by aid of the paper-pulp, and the final addition of glycerin is for the purpose of better preservation.

The Br. P. simply directs that honey shall be melted in a water-bath and strained while hot through flannel previously moistened with warm water. The process of the Fr. Cod. is similar to that of the U. S. P., except that the honey is first diluted with one-fourth its weight of water; no glycerin is used. The P. G. orders that honey (of which 10 Gm. require not more than 0.5 Cc. of normal potassium hydroxide solution for neutralization), mixed with one and a half times its weight of water, shall be digested at 100° C. (212° F.) for one hour, cooled to 50° C. (122° F.), then strained through flannel, and rapidly concentrated on a water-bath until a density of 1.33 is obtained. Various other methods have been suggested involving the use of different clarifying agents, such as white of egg, gelatin and tannin, animal charcoal, aluminum hydroxide, Irish moss, etc., but all require dilution of the honey with water and subsequent concentration by heat, which is apt to darken the color and impair the aroma. In our experience the first-mentioned process yields quite a satisfactory result.

Properties and Tests.—These should correspond to those mentioned under Crude Honey.

Pharmaceutical Uses.—Clarified honey is used as an excipient for some pill masses and confections, and also as a basis of *mellita.*

MELLITA.—*Medicated honeys,* E.; *Mellites,* Fr.; *Honige,* G.—These are simply mixtures of honey with certain medicinal substances. Owing to their proneness to change, the number of these official mixtures has been considerably diminished, and with but few exceptions none are kept on hand, but are prepared extemporaneously when required by the physician.

OXYMELLITA—*Oxymels,* E., Fr.; *Sauerhonige,* G.—are medicated honeys containing acetic acid. (See OXYMEL.)

Action and Uses.—See MEL.

MEL ROSÆ, *U. S.*—Honey of Rose.

Mel rosatum, P. G.; *Mellitum rosatum.—Mellite de roses rouges, Miel rosat,* Fr.; *Rosenhonig,* G.

Preparation.—Fluidextract of rose, 120 Cc.; clarified honey, a sufficient quantity to make 1000 Gm. Into a tared vessel introduce the fluidextract of rose, then add sufficient clarified honey to make the contents weigh 1000 Gm., and mix them thoroughly.—U. S.

If it is desired to make this preparation entirely by measure, 120 Cc. of fluidextract of rose should be mixed with 630 Cc. of clarified honey, or if 12 fluidrachms of the

fluidextract be mixed with 8 fluidounces of clarified honey, the official strength will be practically maintained.

The P. G. requires that 1 part of rose-petals shall be macerated with 5 parts of diluted alcohol for 24 hours; the expressed liquid to be mixed with 9 parts of clarified honey and 1 part of glycerin, and evaporated to 10 parts.

Action and Uses.—(See MEL.) The addition of fluidextract of rose to this preparation renders it more agreeable and somewhat astringent.

MELIACEÆ.—The Mahogany Family.

A family of about 50 genera and some 700 species of shrubs and trees of tropical and warm-temperate regions, of great interest botanically and of much economic importance, if only for its mahogany, the most important of cabinet-woods. It yields several drugs (AZEDARACH, *Oleum Cedrelæ*, *Cocillana*) of commercial interest, and a large number having active properties and important domestic and native uses. Many of these are emetico-cathartic, their action being strikingly like that of ipecac, and many are anthelmintic.

Oleum Cedrelæ, so called "Cedar-wood," or "Red-cedar wood" oil, is a volatile oil distilled from the wood of various species of *Cedrela*, of tropical America. This is the *Cigar-box cedar*, *Spanish cedar*, or *Red cedar of the tropics*, well known as the material of which cigar-boxes are made, and chiefly the product of *C. odorata* L. The bark and wood are used by the natives as a febrifuge and antiperiodic and the fruits as an anthelmintic. A gum, somewhat resembling ACACIA, has been collected from the species named, as well as from the East Indian *C. Toona* Roxb. (*Wandurika* or *Tunp-maram*). The oil is chiefly obtained as a bye-product in distilling the chips and shavings resulting from cigar-box manufacturing. The yield varies in the different species from 0.5 to 2 per cent. or more. The properties differ considerably, from the different species. It is usually of a light-blue color, sometimes greenish. The specific gravity varies from about 0.90 to 0.93. The principal constituent is cadinene. The oil is used for perfuming purposes.

The barks of the mahogany tree (*Swietenia mahogoni* L.) of tropical America, and of *Khaya senegalensis* Guill. et Per., of Western Africa, are used for their astringent and antiperiodic properties. *Soymida febrifuga* (Willd.) Juss. (*Swietenia f.* Willd.) yields the East Indian *Rotun bark*, a useful astringent tonic.

Carapa oil ("crab oil") is the fixed oil of the seeds of several species of *Carapa*. That from *C. Guianensis* Aubl. (*Xylocarpus Carapa* Spr.) is described by Gane as liquid above 20° C. (68° F.), yielding a liquid, oily portion if strongly cooled; specific gravity, 0.923. A bitter principle is extracted with warm water acidulated with acetic acid, which is alkaloidal. Carapa oil has a very nauseous taste and is somewhat purgative. It is not only obnoxious, but toxic to insects. Its great use by the natives is for repelling tormenting tropical insects, by smearing it upon the body or clothing. The importance of its use by travellers for this purpose cannot be overestimated. A very similar oil is yielded to the extent of more than 60 per cent. by the seeds (*Mote nuts*) of the Soudan species *C. procera* DC. (*C. Toulouconna* Guill. et Per.); this oil is known as *Tallicouna*, *Coundi*, or *Kundah* oil. It is a much-used anthelmintic in its home. The barks of both the above species are used as antiperiodics.

Cocillana is the bark of *Guarea Rusbyi* (Britton) Rusby (*Sycocarpus R.* Britton), a good-sized tree of the eastern Andean slope in Bolivia. The bark is from 3 to 10 Mm. ($\frac{1}{8}$ to $\frac{2}{5}$ In.) thick, strongly and roughly fissured, of an ashy-gray color externally and yellowish-brown internally. It has a weak but fibrous fracture, a peculiar and rather nauseating odor, and a rather weak but nauseous taste. It contains large oblong resin-cells containing a caoutchouc-like substance. It contains an alkaloid, *Rusbyine*, about 2.5 per cent. of 2 resins, an equal amount of fat, and a little tannin. Its action is closely similar to that of ipecac, for which it can be successfully substituted in nearly all cases. In overdoses it is a drastic cathartic.

Other species of the genus Guarea exert a similar action. *G. trichilioides* L. (Yto?), *G. Aubletii* Juss. (*Trichilia Guarea* Aubl.), the *Bois Balle* of Brazil and Guiana, *G. purgans* St. Hil., the Brazilian *Marinheiro*, and *G. spiciflora* Juss., the Brazilian *Marinheiro da folha larga*, have been named. The genus *Trichilia* is closely related and very similar, and a number of its species have similar properties. *T. emetica* Vahl. is the Egyptian *Djong el Kai*. *T. cathartica* Mart. (*Moschoxylon c.* Mart. is the Brazilian *Marinheiro da folha minha*. *T. Catigua* A. Juss. is the Brazilian *Aohite*. *T. moschata* Sw. is the *Juribali* of Jamaica. In India, the bark of *Walsura Piscidia* Roxb. is used under the name *Walurasi*, as a fish poison, and it is recognized as an emetic and emmenagogue. *Dysoxylon Blancoi* Vidal is the source of the Philippine medicinal bark *Igiw* or *Agiw*, much used as an anthelmintic, antiperiodic, and emmenagogue, and in large doses emetic.

Naregamia alata W. et A. yields the Indian drug *Goancse ipecac*. The plant is an under-

shrub a few inches in height, the stems terminating in a cluster of alternate, trifoliolate entire, or dentate leaves with winged petioles. The roots somewhat resemble ipecac. They are of a rich brown color, or greenish above, tortuous and possess a thick friable bark. The odor and taste are much like those of cocillana, above described. It contains the alkaloid *Naregamine*, an abundance of fat, wax, etc. Its properties appear almost identical with those of Cocillana.

MELISSA.—Melissa.

Folia melissæ, P. G.; *Melissa officinale*, Fr. Cod.; *Folia melissæ citratæ or citrinæ.—Balm, Lemon, Garden, Blue*, or *Sweet balm, Lemon Lobelia, Sweet Mary, Honey plant, Pimentary*, etc., E.; *Melissenblætter, Citronenkraut*, G.; *Herbe au citron, Celine, Citronelle*, Fr.; *Erba Limoncina, Cedronella*, It.; *Melisa, Toronjil*, Sp.; *Herva cidreira*, Port.

The leaves and tops of *Melissa officinalis* L. (*M. o. citrata* Bisch.—Fam. *Labiatæ*).

Melissa is official in most pharmacopœias.

Origin.—The plant is a perennial herb, with pubescent, branching stems 2 to 4 feet long from a woody rhizome. It is native of southern Europe and adjacent Asia, and is considerably cultivated. The leaves lose about 75 per cent. in drying.

Description.—Leaves slenderly petioled, the blades rarely exceeding 5 Cm. (2 In.) in length and about two-thirds as broad, ovate, rounded to subcordate at the base, obtuse, rather coarsely crenate-dentate, thin, pale-green, prominently veiny on the lower surface, sparsely hairy, the hairs soft and very fine; flowers in about 4-flowered axillary cymules, with a bell-shaped, 13-nerved, 2-lipped, 5-toothed calyx, a whitish or purplish, tubular, curved, 2-lipped corolla and didynamous stamens; odor lemon-like when crushed and warmed in the hand; taste bitterish, slightly astringent, scarcely aromatic.

When fresh, the leaves are delightfully lemon-scented, but quickly lose their fragrance after drying. Hence, the Austrian Pharmacopœia requires that they be renewed annually.

Constituents.—The leaves contain, besides the common constituents of plants, a small quantity of tannin and bitter principle and about $\frac{1}{8}$ to $\frac{1}{4}$ per cent. of volatile oil, which is colorless or yellowish, has a specific gravity of about 0.89, dissolves in about 5 parts of alcohol, has a specific gravity of 0.85 ,and contains a stearopten.

Action and Uses.—An infusion of balm [$\frac{1}{2}$ ounce (16 Gm.) to 1 pint (480 Cc.)], if drunk while hot, greatly favors diaphoresis and forms an excellent adjuvant in the treatment of febrile diseases. It may be taken in doses of from 2 to 4 fluidounces (60–120 Cc.).

Allied Products.—*M. cordifolia* Pers., perhaps a variety of *M. officinalis*, has larger, somewhat woolly leaves, of rather disagreeable odor. The leaves of *Nepeta cataria citriodora* L. have a similar odor, but are cordate-ovate, gray-green, soft-downy above and tomentose underneath.

FIG. 270.

Melissa (½ Nat.).

MENISPERMACEÆ.—The Moonseed Family.

This is a family of 50 to 60 genera and some 300 or 400 species, mostly woody twiners of the tropics of both hemispheres. Medicinally, the plants are noted for containing alkaloids and other bitter principles, on which account many of them are extensively used as bitter tonics, antiperiodics, and alteratives. A few are actively poisonous. CALUMBA, PAREIRA, PICROTOXINUM, and some allied drugs are elsewhere considered in this work. In Brazil, various species of *Abuta* are used much like Pareira. The root of *Tinospora cordifolia* (DC.) Miers (*Cocculus c.* DC.; *Chasmanthera c.* DC.) is a favorite substitute for Calumba, in India. Numerous species of *Cocculus* are similarly employed in various countries. The roots of various species of *Stephania* are employed like Serpentaria. *Cyclea peltata* Hook. f. et Th. (*Cocculus p.* DC.), of the East Indies, apparently contains the alkaloid *buxine*, and is used as a bitter tonic.

MENISPERMUM.—Menispermum.

Canadian moonseed, Yellow parilla, Yellow or *Texas sarsaparilla, Vine maple,* E.; *Canadisches Mondkorn,* G.; *Ménisperme du Canada,* Fr.

The dried rhizome and roots of *Menispermum Canadense* L. (Fam. *Menispermaceæ*).

Origin.—The plant is a herbaceous twiner of eastern and central North America, having peltate, roundish-cordate, and angular leaves, small clusters of greenish-yellow flowers, and black, glaucous, roundish kidney-shaped drupes. The drug collected in the southwest presents quite a different appearance from that of the north, and may yet be found specifically distinct.

Description.—Rhizome in simple or little-branched, rather straight pieces, often several feet in length and 2 to 5 Mm. ($\frac{1}{12}$ to $\frac{1}{5}$ In.) thick, consisting of joints mostly 2.5 to 5 Cm. (1 to 2 In.) long, and bearing fine, hair-like, wavy, branched, spreading roots of similar, or a little darker, color; yellowish-brown or gray-brown, bearing straight and regular rib-like wrinkles; fracture soft and tough; transverse section exhibiting a white (becoming yellow with long keeping) pith of very irregular relative thickness, a yellowish-white wood with broad, porous wood-wedges which are longer on the lower side, and a somewhat darker, rather thin bark; almost inodorous and bitter.

Maisch found the rhizome to contain a small quantity of berberine and a larger proportion of the white alkaloid *menispine,* which has a bitter taste, neutralizes acids completely, and yields precipitates with the group reagents for alkaloids, differing from oxyacanthine and menispermine, and insoluble in benzene and alkaline liquids; it dissolves in 75 parts of water, in 6 parts of alcohol, in 40 parts of ether, and in 20 parts of chloroform, and gives with sulphuric acid a brown color, gradually fading; with nitric acid, a yellow color; and with fused zinc chloride, a brownish-yellow color. Starch, gum, resin, tannin, and other common constituents of plants also occur.

Action and Uses.—Menispermum is probably devoid of medicinal activity. It is thought by some to be tonic and alterative, and has been employed as a substitute for sarsaparilla in the treatment of scrofulous affections. It is rarely used by practitioners.

MENTHA PIPERITA, *U. S.*—Peppermint.

Folia menthæ piperitæ, P. G.; *Menthe poivrée,* Fr. Cod.; *Brandy mint, Lamb mint,* E.; *Pfefferminzblätter,* G.; *Yerba buena piperita,* Sp.; *Hortela Pimenta,* Port.

Fig. 271.

Peppermint: *a*, branch (¾ Nat.); *b*, flower (× 3); *c*, leaf; *d*, hair, containing menthol crystals, greatly enlarged.

The dried leaves and flowering tops of *Mentha Piperita* L. (*M. Balsamea* W.—Fam. *Labiatæ*).

Peppermint is official in most pharmacopœias, a number of which caution against other species with which there is danger of confounding it, especially with Spearmint. The Austrian specifies that it should be renewed annually.

Origin.—Peppermint is a perennial herb, propagating by runners or rhizomes, and covering large areas of low or swampy land, often to the total exclusion of other vegetation. The erect or partly prostrate stems are mostly from 60 to 100 Cm. (2 to 3 Ft.) long, are quadrangular, nearly smooth, and often purplish. It is a native of central and northern Europe and has become abundantly naturalized in many, if not in most temperate regions. The fragrance and general quality are distinctly improved by careful cultivation, and the commercial article, as well as the oil distilled from it, is now almost wholly the product of cultivated plants. The largest amount of peppermint is produced in the United States, especially in Michigan and New York, Germany standing next. English peppermint has a higher repute than

any other. The very large quantity produced in Japan is mostly consumed in the manufacture of menthol. The drug loses about 80 per cent. in drying. An interesting account of its history and cultivation may be found in *Proc. Amer. Pharm. Assoc.*, 1903, p. 271 *et seq.*

Description.—Very sparingly and obscurely hairy, the hairs short and stout, usually containing menthol crystals in one or more cells; stems quadrangular, usually purplish; leaves opposite, exstipulate, petioled, the petioles winged toward the summit, the blades usually less than 5 Cm. (2 In.) long and about half as broad, ovate, with the rounded base very abruptly produced into the petiole, acute, sharply serrate, thin, wrinkled, of a bright- and usually light-green; flower-spikes oblong or oval, 1 to 2 Cm. ($\frac{2}{5}$ to $\frac{4}{5}$ In.) broad, with rounded summit, dense, or somewhat interrupted at the base; flowers about 6 Mm. ($\frac{1}{4}$ In.) long, the calyx tubular, 10-nerved, scarcely 2-lipped, 5-toothed; corolla light-purple, nearly equally 4-lobed, or one lobe (consisting of 2 united) a little larger; stamens 4, short, equal; fruit of 4 ovoid, smooth nutlets, about 0.5 to 0.75 Mm. long and half as broad; odor strong, but not heavy, characteristic; taste characteristic, pungent, and cooling.

The powder, while exhibiting many interesting elements, is especially characterized by subglobular, shortly and stoutly stalked oil-glands, and hairs, in one or more of the cells of which menthol crystals frequently occur.

Constituents.—The only important constituent of peppermint is about 1 per cent. of volatile oil (see OLEUM MENTHÆ PIPERITÆ and MENTHOL), with which there are a very small amount of tannin, much chlorophyll, and ordinary plant-constituents.

Action and Uses.—The activity of this herb depends upon the volatile oil which it contains (see OLEUM MENTHÆ PIPERITÆ). Peppermint may be employed as a carminative, stimulant, and anodyne. It may be given in the form of an infusion for the relief of nausea and flatulent colic. The fresh leaves when bruised may be applied for the relief of local pains, and when applied to the epigastrium are of value in the treatment of infantile diarrhœa.

Other Species.—The genus *Mentha*, L., is credited with some 15 species, although their great variability has resulted in the proposal of many more names. They are, as a class, among the most highly valued aromatics. Besides peppermint and spearmint (see next title), the species yielding MENTHOL, considered under that title, and *M. Pulegium*, considered under HEDEOMA, the following are worthy of notice:

M. crispa L. is the *Crisped* or *Curled-leaved*, *Cross* or *Balm mint*, or (G.) *Krauseminze*. It is a European species, sparingly naturalized in the eastern United States. It is sparsely pilose, the erect or ascending stems 1 to 3 feet long, the leaves petioled, excepting the uppermost, ovate, acutish, rounded to subcordate at the base, the margin crisped, the inflorescence much as in peppermint. This species was formerly official in the P. G. as *Folia menthæ crispæ*, together with the very similar leaves of *M. crispata* Schrad.

M. citrata Ehrh. is the *Bergamot* or *Fish mint* of Europe, and is a smaller and more slender species, its leaves larger, thinner, mostly obtuse, sharply serrate, the flower-spikes more interrupted than in the last.

M. rotundifolia (L.) Huds. (*M. spicata r.* L.; *M. sylvestris glabra* Koch), the *Round-leaved*, *Apple*, or *Patagonia mint*, is apparently a native of temperate or subtropical South America, and considerably naturalized in the United States. It is somewhat glandular-pubescent, its stems stout, but weak and prostrate at the base, the subsessile to sessile and clasping leaves oval- or ovate-rotund, obtuse, mostly cordate at the base, crenate-serrate, thick, very rugose, the flower-spikes long, but thick, and interrupted.

MENTHA VIRIDIS, *U. S.*—Spearmint.

Herba menthæ acutæ (or *romanæ*).—*Brown*, *Garden*, *Lamb*, or *Mackerel mint*, E.; *Grüne Minze*, *Roemische Minze*, G.; *Menthe verte*, Fr. Cod.; *Menthe romaine*, *Baume vert*, Fr.; *Yerbe Buena*, Sp.; *Hortela vulgar*, Port.

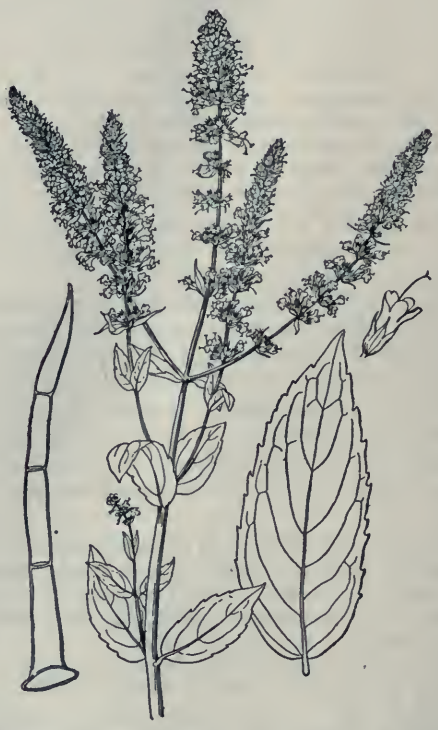
The dried leaves and flowering tops of *Mentha spicata* L. (*M. spicata viridis* L.; *M. viridis* L.; *M. sylvestris glabra* Koch.—Fam. *Labiatæ*).

Spearmint is official only in the United States and French pharmacopœias.

Origin.—The nativity and range of Spearmint are the same as those of Peppermint. It also is cultivated, but less extensively than the latter plant. Its habit is the same as that of Peppermint, but the stems are scarcely so long. It is well distinguished by its longer and more slender, acute flower-spikes and by its heavier and less pleasing odor.

Description.—Sparingly and obscurely hairy, the hairs short and stout, without menthol crystals in their cells; branches quadrangular, slender, usually pale-green, rarely purplish; leaves opposite, exstipulate, very shortly petioled, the blades usually less than 5 Cm. (2 In.) long and about one-third as broad, lanceolate or lanceovate, rounded at the base, acuminate

FIG. 272.



Spearmint: *a*, branch (Nat.); *b*, flower (× 3); *c*, leaf; *d*, hair (much enlarged).

and acute, sharply serrate, thickish and rigid, deep- and usually dark-green; flower-spikes usually appearing clustered at the summit, interrupted, elongated and acute, about 5 to 8 Mm. (^{1} to $\frac{1}{3}$ In.) thick; flowers about 3 Mm. ($\frac{1}{8}$ In.) long, the calyx-tube nearly equally 5-toothed, 10-nerved, the corolla light-purple, nearly equally 4-lobed, the stamens 4, nearly equal, rather long; odor characteristic, aromatic, rather heavy; taste characteristic, pungent.

Constituents.—The only appreciable difference in composition between Spearmint and Peppermint is in the character of the volatile oil (see OLEUM MENTHÆ VIRIDIS).

Action and Uses.—The properties of this plant are identical with those of MENTHA PIPERITA (which see).

MENTHOL, *U. S.*, *Br.*—Menthol.

Mentholum, P. G., Fr. Cod. *Pipmenthol, Peppermint camphor*, E.; *Menthol, Camphre de menthe*, Fr.; *Menthol, Pfefferminzkamfer, Mentha-Kamfer, Pip-Menthol*, G.

Formula, $C_{10}H_{19}OH$ or $C_6H_9.OH.CH_3.C_3H_7$. Molecular weight, 154.98.

Menthol is a stearopten (having the nature of a secondary alcohol), obtained from the official oil of peppermint (from *Mentha piperita* L.), or from the Japanese or Chinese oil of peppermint (from *Mentha arvensis piperascens* Holmes, and *Mentha arnavensis* Holmes).—Fam. *Labiatæ*.

Origin and Preparation.—The Chinese and Japanese solid oil of peppermint, which consists mainly of menthol, was shown by E. M. Holmes to be prepared from the

varieties *glabrata* and *piperascens* of *Mentha arvensis* De Candolle. This volatile oil, carefully rectified by steam, is cooled by means of ice and salt to —22.2° C. (—8° F.), and after it has solidified the temperature is allowed to rise very slowly, the liquid portion being drained off from time to time. This article has become known in the United States as *pipmenthol.* The yield is about 20 per cent. of the weight of the oil. The A. M. Todd Company, of Kalamazoo, Mich., has prepared a very handsomely crystallized and perfectly dry menthol from oil of peppermint distilled from *Mentha piperita* grown in the United States.

Properties.—Menthol forms colorless, acicular, or prismatic glossy crystals, which, seen in quantity, have a white appearance; if rapidly congealed, the crystals are thin, stellately arranged, and of a satiny lustre. They melt at 43° C. (109.4° F.) U. S., P. G., 42° C. (107.6° F.) Br., to a colorless liquid, boiling at 212° C. (413.6° F.), and have an agreeable odor and taste of peppermint, producing, if air is inhaled, a sensation of coolness. The Chinese menthol appears either in fused crystalline masses or in colorless acicular crystals, which are more or less moist from adhering oil, and differ somewhat in odor from that of pipmenthol. Menthol dissolves sparingly in water, but is freely soluble in alcohol, ether, chloroform, and other solvents of volatile oils; the solutions have a neutral reaction to test-paper. Boiled with sulphuric acid diluted with half its volume of water, menthol acquires an indigo-blue or ultramarine color, the acid becoming brown. Menthol should be entirely volatilized by the heat of a water-bath (absence of magnesium sulphate and other saline or waxy impurities). In contact with thymol, which has a higher melting-point, it becomes liquid (Flückiger). Triturated with an equal weight of hydrated chloral, thymol, or camphor, an oily, colorless liquid is produced, soluble in alcohol, benzin, chloroform, ether, and carbon disulphide, and on being mixed with sulphuric acid acquiring a blue color, the mixture yielding with alcohol a nearly colorless solution (H. V. Becker, 1886).

If a few crystals of menthol be dissolved in 1 Cc. of glacial acetic acid, and then 3 drops of sulphuric acid and 1 drop of nitric acid added, no green color should be produced (absence of thymol).—U. S. Thymol may also be detected by the development of a deep rose-red color upon heating with sulphuric acid.

Menthol readily combines with acids to form the corresponding esters. Menthyl acetate and valerianate are known to be present in oil of peppermint. Heated with potassium dichromate and sulphuric acid, menthol is changed to the lævorotatory ketone menthone, $C_{10}H_{18}O$. If dehydrated by means of zinc chloride, potassium acid sulphate, etc., it is reduced to the hydrocarbon menthene, $C_{10}H_{18}$. By the action of hydriodic acid and phosphorus menthol is converted into hexahydrocymene, $C_{10}H_{14}H_6$, and upon being heated together with anhydrous copper sulphate to 250°–280° C. (482°–506° F.), it is made to yield cymene, $C_{10}H_{14}$.

Solutions of menthol are lævorotatory. Its alcoholic solution of 10 per cent. strength shows $[a]_D = -50.1°$, and a 20 per cent. solution, —49.3°.

Pharmaceutical Uses.—Menthol is used both in form of ointment and plaster and in the form of cones, either pure or adulterated with spermaceti and paraffin.

Under the name *validol*, a mixture of 2 parts of menthyl valerianate and 1 part of menthol has been placed on the market in form of a colorless liquid of thin syrupy consistence, sparingly soluble in water but readily soluble in alcohol, ether, and chloroform.

Action and Uses.—Menthol has been employed internally as a remedy for gastric pain. When given in large doses, it impairs the motor and sensory activity of the cord and nerve-trunks. In the form of a cone it has been largely employed as a local application for the relief of headache, toothache, and superficial neuralgias. Its application produces at first a cooling sensation, which is followed by one of burning. A 2 per cent. solution in water may be employed locally as a palliative in the treatment of pruritus ani et vulvæ and in urticaria, and a 5 per cent. solution in bland oil as a spray may be used with excellent results in acute coryza and hay fever. An ethereal solution containing from 10 to 50 per cent. of the drug may be tried for the purpose of aborting superficial inflammations, such as boils and carbuncles. The dose is from 1 to 2 grains (0.06–0.12 Gm.), either in pill or in oil.

MENYANTHES.—Bogbean; Buckbean.

Folia (or *Herba*) *trifolia fibrina*, P. G.; *Trèfles d'eau* (or *de marais*), Fr. Cod.—*Marsh trefoil, Water shamrock, Bog-hop, -nut,* or *-myrtle, Brook-bean*, E.; *Wasserklee, Bitterklee, Fieberklee, Dreiblatt*, G.; *Trébal acuatica*, Sp.

The dried leaves of *Menyanthes trifoliata* L. (Fam. *Gentianaceæ*).

Fig. 273.

Menyanthes (½ Nat.).

Origin and Description.—From a smooth perennial herb, growing in boggy places, usually in water, through most of the north-temperate zone. The horizontal rhizome is yellowish-white, 1 to 2.5 Cm. (⅖ to 1 In.) thick, fleshy, and invested by the sheathing bases of the petioles. The leaves grow from near the base of the stem, which is mostly a foot or two high, and terminates in a raceme of about 15 to 20 white or rose-colored, fringed flowers. The leaves are mostly gathered in the spring and lose about 85 per cent. in drying. The leaves are on petioles 10–15 Cm. (4 or 6 In.) long, ternate, the leaflets sessile, 5–8 Cm. (2 to 3 In.) long, obtuse, oblong or obovate, entire or slightly crenate, smooth, and pale-green. They are inodorous, and have a very bitter taste, free from astringency.

Constituents.—The important constituent of Menyanthes is the very bitter, whitish, amorphous, neutral glucoside *menyanthin* ($C_{30}H_{46}O_{14}$), which melts at 100° to 115° C. (212° to 239° F.), is soluble in alcohol and chloroform, with difficulty in water, and insoluble in ether, and yields a white precipitate with tannic acid. When boiled with dilute acids it is resolved into sugar, a brown resin, and *menyanthol*, the latter being oily, volatile, heavier than water, and having an odor resembling that of bitter almonds. The leaves contain a pectin compound, which causes the infusion, sweetened with sugar, to gelatinize in a few days; this compound is insoluble in diluted alcohol.

Pharmaceutical Preparation.—Fluidextract of Menyanthes, N. F.

Action and Uses.—Buck-bean is a tonic, purgative, and emmenagogue. In large doses it acts as an emetic and vermifuge. The remedy has been recommended in the treatment of atonic dyspepsia, malarial fevers, rheumatism, amenorrhœa, scrofula, scurvy, and chronic cutaneous eruptions. The dose of the powdered drug is from 10 to 30 grains (0.60–2 Gm.). An infusion [½ ounce (16 Gm.) to 1 pint (480 Cc.)] may be given in doses of from 1 to 2 fluidounces (30–60 Cc.). As a purge double this dose may be given.

METHYLENI BICHLORIDUM.—Methylene Bichloride.

Methylenum bichloratum.—Dichlormethane, Chloro-methyl, E.; *Chlorure de méthyle monochloré, Ether chlorhydrique monochloruré de l'esprit de bois*, Fr.; *Methylenchlorid, Chlormethylchlorür*, G.

Formula, CH_2Cl_2. Molecular weight, 84.27.

Preparation.—Chlorine gas is conducted into a glass globe containing methyl chloride, CH_3Cl, which glass is drawn out below so as to form a thin tube, passing into one aperture of a Woulfe's bottle, the second tubulure being connected, by means of a bent glass tube, with a second Woulfe's bottle placed in ice, and this with a flask cooled by means of a freezing-mixture; the liquid condensed in the Woulfe's bottles is chiefly chloroform, while that condensing in the flask will be pure methylene bichloride. This is Regnault's process, by whom the compound was discovered (1840). It can also be obtained by the reduction of chloroform (in alcoholic solution) by zinc and hydrochloric

acid; the heavier liquid is separated and purified by successive treatment with soda solution, sulphuric acid, water, calcium chloride, and fractional distillation.

Properties.—Methylene bichloride is a colorless liquid, having at 15° C. (59° F.) the specific gravity 1.351, and boiling between 40° and 41° C. (104°–105.8° F.). Its odor resembles that of chloroform. It has no action upon test-paper, is soluble in alcohol and ether, and scarcely affected by alcoholic solution of potassium hydroxide. It is decomposed when exposed to light and air, the change being prevented by the addition of a little alcohol. Its vapor has the density 3.012 and burns with a bright flame.

In composition it may be regarded as the chloride of methylene (CH_2) or as a derivative of methane, CH_4.

English Methylene Chloride, or methylene, is a mixture of methylene chloride and ether; it was recommended as a safe anæsthetic in doses of from 1 to 4 drachms (Richardson), but is not so free from danger as its originator believed. Care should be taken to distinguish between this mixture and the definite chemical compound above mentioned.

A mixture of chloroform and methyl chloride has also figured in commerce as "methylene chloride" (Helbing).

Action and Uses.—Methylene bichloride has been proposed as a general anæsthetic safer than chloroform. It is, however, rarely employed on account of its high price, and any preparation offered at a low figure is in all probability an impure article. It is said to act more rapidly than chloroform, to cause less muscular relaxation, and to interfere less with the circulatory and respiratory functions than the older anæsthetic. The average quantity required for the production of anæsthesia is 1 fluidrachm (4 Cc.), every 5 minutes. It may be administered internally in doses of from 5 to 15 minims (0.3–1 Cc.).

Allied Compounds.—Methyl Chloride. *Chlormethyl, Monochlormethane.* CH_3Cl. Molecular weight, 50.09.—A gaseous compound first proposed by Berthelot, and obtained by the reaction between methyl alcohol and hydrochloric acid in the presence of zinc chloride. After purification by means of water, acid, and alkali, it occurs as a colorless gas with an ethereal odor; it is soluble in one-fourth its volume of water, much more so in alcohol, and freely in ether and chloroform. Under a pressure of 5 atmospheres at normal temperature methyl chloride is a liquid which should be neutral to test-paper and unaffected by silver nitrate or potassium iodide and starch paste. The compressed liquid form of methyl chloride has been recommended for use as a spray to produce local anæsthesia.

Carbon Tetrachloride. *Tetrachlormethane.* CCl_4. Molecular weight, 152.63.—A transparent, colorless liquid, of the specific gravity 1.599, boiling at 77° C. (170.6° F.), and of an agreeable aromatic flavor. It is obtained in an impure form when dry chlorine is first passed through a bottle containing carbon disulphide, and then through a porcelain tube filled with pieces of porcelain and kept at a bright-red heat; the vapors are condensed in a cooled receiver, forming a yellowish-red liquid, which is a mixture of carbon tetrachloride and sulphur chloride. The sulphur chloride is removed by slowly adding the liquid to an excess of potash lye or milk of lime, the mixture being set aside and agitated from time to time till the sulphur compound is decomposed, and then distilled. Carbon tetrachloride passes over, and, if necessary, may be freed from remaining carbon disulphide by further treatment with caustic potash. It has been recommended in place of benzin, gasoline, etc., over which it has the advantage of non-inflammability and non-explosiveness. For detailed account of its uses, see *Proc. Am. Pharm. Assoc.*, 1903.

METHYLIS IODIDUM.—Methyl Iodide.

Iodure de méthyle, Fr.; *Jodmethyl*, G.

Formula, CH_3I. Molecular weight, 140.81.

Preparation.—This compound was first obtained by Dumas and Peligot (1835) by adding very gradually 1 part of phosphorus to a solution of 8 parts of iodine in 12 or 15 parts of methyl alcohol, agitating the distillate with water and rectifying. According to Wanklyn (1867), potassium iodide and anhydrous methyl alcohol are mixed in a retort in equivalent proportions; dry hydrochloric acid gas is passed into the mixture, which is then distilled, and the distillate purified as before.

Properties.—Methyl iodide is a colorless liquid of an ethereal odor and the specific gravity 2.199 at 0° C. (32° F.). It boils at 43.8° C. (111° F.), and by the aid of a wick burns with difficulty, giving off violet vapors. It turns brown on exposure to light, and in the cold unites with water to form a crystalline hydrate.

Action and Uses.—This substance was formerly proposed as a general anæsthetic, but because of its irritant properties its employment as such has been abandoned. It may be applied under a watch-crystal for the purpose of producing vesication. When employed in this manner, the maximum pain is felt in from 5 to 15 minutes, after which it should be removed.

Methyl iodide is largely used in the synthetic manufacture of numerous chemicals.

Allied Compound.—Methyleni Iodidum, *s.* Biniodidum. CH_2I_2. Molecular weight, 267.03.—Prepared by Butlerow (1859) by acting upon iodoform with sodium ethylate. It is readily formed by heating chloroform with very concentrated hydriodic acid for several hours to near 130° C. (266° F.). It is a yellow liquid having the specific gravity 3.34, congealing to glossy scales near the freezing-point, and boiling at 180° C. (356° F.), at the same time suffering partial decomposition.

METHYLIS SALICYLAS, *U. S.*—Methyl Salicylate.

Artificial or synthetic oil of wintergreen, E.; *Salicylate de méthyle*, Fr.; *Methylsalicylat, Künstliches Wintergrünöl*, G.

An ester produced synthetically; it is the principal constituent of oil of gaultheria and oil of betula. For flavoring purposes, oil of gaultheria, oil of betula, and methyl salicylate may be regarded as identical products. It should be kept in well-stoppered bottles, protected from light.—U. S.

Formula, $CH_3C_7H_5O_3$ or $C_6H_4(OH)COOCH_3$. Molecular weight, 150.92.

Preparation.—The process probably most used is the one which is employed extensively for the preparation of compound ethers, and consists in heating salicylic acid and methyl alcohol together in the presence of sulphuric acid. The reaction occurring may be expressed by the following equation: $C_6H_4OHCOOH + CH_3OH = C_6H_4OHCOOH_3 + H_2O$; the sulphuric acid serving only to abstract the water as fast as eliminated. The newly formed methyl salicylate floats on the surface of the liquid and is subsequently purified by distillation.

Properties.—Methyl salicylate is a colorless, or slightly yellowish liquid, having the characteristic, strongly aromatic odor, and the sweetish, warm, and aromatic taste of oil of wintergreen, with the essential constituent of which it is identical, and in place of which it may be used. Specific gravity, 1.180–1.185 at 25° C. (77° F.). Boiling-point, 219° to 221° C. (462.2°–429.8° F.). It is optically inactive. Sparingly soluble in water, but soluble in all proportions in alcohol, glacial acetic acid, and carbon disulphide. The alcohol solution is neutral or slightly acid to litmus-paper. If a drop of methyl salicylate be shaken with a little water, and a drop of ferric chloride test-solution subsequently added, a deep-violet color will be produced. When heated on a water-bath, in a flask provided with a suitable condenser, it should yield no distillate having the characteristics of alcohol or chloroform. If to 1 Cc. of methyl salicylate, contained in a capacious test-tube, 10 Cc. of sodium hydroxide test-solution be added, and the mixture agitated, a bulky, white, crystalline precipitate will be produced; and, if the test-tube, loosely corked, be subsequently allowed to stand in boiling water for about 5 minutes, with occasional agitation, a clear, colorless or faintly yellowish and complete solution should be obtained without the separation of any oily drops, either on the surface or at the bottom of the liquid (absence of other volatile oils or of petroleum). If the alkaline liquid thus obtained be subsequently diluted with about 3 times its volume of water, and a slight excess of hydrochloric acid added, a white crystalline precipitate will be produced, which, when collected on a filter, washed with a little water, and recrystallized from hot water, should respond to the tests of identity and purity described under Acidum Salicylicum (absence of methyl benzoate, etc.).—U. S.

Action and Uses.—This preparation apparently differs in no particular from oil of *wiutergreen*. (See Oleum Gaultheræ.)

METHYLTHIONINÆ HYDROCHLORIDUM, *U. S.*—Methylthionine Hydrochloride.

Tetramethylthionine hydrochloride, Methylene blue, E.; *Chlorhydrate de tetraméthylethionine*, Fr.; *Tetramethylthioninchlorid, Methylen Blau*, G.

Formula, $C_{16}H_{18}N_3SCl$. Molecular weight, 317.36.

Preparation.—When para-amido-dimethylaniline, also known as dimethyl-para-

diamidobenzene and dimethyl-para-phenylendiamine, $C_6H_4(NH_2)N(CH_3)_2$, is treated in hydrochloric acid solution with hydrogen sulphide and subsequently with ferric chloride, tetramethylthionine hydrochloride is produced. It may also be prepared by treating para-amido-dimethylaniline hydrochloride with sodium nitrite and then successively with hydrogen sulphide and ferric chloride.

Properties and Tests.—Methylene blue occurs as a dark-green, crystalline powder, or in form of prismatic crystals having a bronze-like lustre. It is readily soluble in water and somewhat less readily in alcohol, the solutions having a deep-blue color. The addition of hydrochloric acid to its aqueous solution changes the color to a lighter shade of blue. The addition of sodium hydroxide test-solution to the aqueous solution changes the color to a purplish shade, and if added in excess, produces a precipitate having a dull-violet color. The dry powder dissolved in sulphuric acid containing powdered zinc produces a solution which, upon standing, is gradually decolorized. 2 Gm. of methylene blue, when heated until it is decomposed, should leave not more than 0.004 Gm. of residue, which, when examined, should be free from zinc oxide (absence of commercial dye and other mineral impurities). 2 Gm. of methylene blue ignited with dry sodium carbonate and potassium nitrate should leave a residue which should not respond to the modified Gutzeit's test for arsenic, given under ARSENI TRIOXIDUM.—U. S. Methylene blue stains during life the axis cylinders of both sensory and motor nerves, and has proved the best stain for the plasmodia found in the blood corpuscles of malarial patients.

Methylene blue is usually dispensed in capsules, either dry or in form of a mass. Some little care is necessary to avoid soiling the hands and clothing of the operator. When it is ordered in powder form, the best plan would seem to be to rub the methylene blue into powder, not too fine, in a glass mortar, and divide the powder into the prescribed number of doses on glazed paper, and then carefully transfer to the capsules. If a mass is to be made, methylene blue may be rubbed into powder with half its weight of powdered licorice-root and then massed with glucose or some similar excipient. By keeping the hands and pill-tile well dusted with licorice powder, it is possible to prevent coloring while the mass is divided into the required number of cylinders, which may then be transferred to the capsules in the usual manner with the aid of a long needle.

Commercially, methylene blue is sometimes found as the double chloride of zinc and tetramethylthionine, in which form it is used as a dye, but is unfit for medicinal purposes, hence the test for absence of zinc, given above. It must not be confounded with methyl blue, the sodium salt of triphenyl-para-rosaniline-trisulphonic acid, which is made by treating pararosaniline with aniline and the resulting product with sulphuric acid. A solution of methyl blue, upon the addition of sodium hydroxide, changes to reddish brown, whereas the color of methylene-blue solution changes to violet.

Action and Uses.—Methylene blue has been used with some success in intermittent malarial fever. It is not nearly so effective as quinine, but may be tried in those cases in which quinine fails. If employed, it should be administered in doses of from 2 to 4 grains (0.12–0.25 Gm.) every 4 hours, and be continued for some time after the paroxysms have ceased. It has been highly recommended by Horwitz in the treatment of the earlier stages of the gonorrhœal urethritis, and may be given alone in tablet or pill, or combined with balsamic drugs dispensed in capsule. The dose for this purpose is 1 grain (0.06 Gm.) three times a day. It has been used to test the eliminative function of the kidney, by injecting into a muscle 1 grain dissolved in 10 minims of water. If the kidneys are not diseased the urine should show a greenish discoloration in from 15 to 30 minutes, and continue discolored for 36 hours.

METHYSTICUM.—Kava; Kava-kava.

Awa, Ava, Kawa.

The dried root of *Macropiper latifolium* (L. f.) Miq. (*Piper l.* L. f; *Piper Methysticum* Forst.; *Macropiper M.* Miq.; *Methysticum-M.* Lyons; *M. esculentum* Raf.—Fam. *Piperaceæ*).

Origin.—From a tall, soft-wooded shrub, native and largely cultivated in the Polynesian Islands, where the drug is used in the production of a beverage which induces a peculiar kind of intoxication, the motor functions, especially of the lower limbs, being incoördinated, but the intellectual functions little or not at all affected. More or less of

a general anæsthetic effect is also produced, as well as profuse diuresis. The natives prepare it by chewing and then fermenting the mass; the Europeans, by powdering and macerating. It may be employed either without or after alcoholic fermentation.

Description.—Blackish- or dark-brown externally, white internally; root consisting of a large knotty crown 5 to 15 Cm. (2 to 6 In.) thick, which is light, soft, spongy, and very starchy, the fibrovascular bundles thin and very crooked, and of numerous branches which are mostly 30 to 60 Cm. (1 to 2 Ft.) long and 1 to 2.5 Cm. ($\frac{2}{5}$ to 1 In.) thick, little-branched, tough-fibrous and readily separating into their fibrovascular bundles, lighter without and more yellowish within than the crown; odor slight; taste agreeably pungent, starchy, slightly bitter.

Constituents.—What is regarded as the important active constituent of Kava is about 2 per cent. of two resins, the alpha- and the beta-, the former more strongly anæsthetic. Bossingham differentiates a third resin. There is a very small amount of the alkaloid *kavaine*, of which little is known. *Methysticin* is a crystallizable neutral and apparently inactive body, soluble in alcohol and ether, and regarded as the methyl-ester of methysticinic acid. Authorities differ as to whether this is identical with "kavahin." About one-half of the weight of Kava consists of starch. The ash amounts to about 2.5 per cent.

Pharmaceutical Preparation.—Fluidextract of Kava, N. F.

Action and Uses.—If a solution of kava resin be injected hypodermically, it occasions a local anæsthesia lasting for a number of days. If the quantity injected be sufficiently large, the local effect is followed by complete paralysis due to the depressing action of the drug upon the motor side of the cord. This remedy increases the force, but decreases the rapidity of the heart's action, and at first stimulates and later depresses the respiratory center. Locally applied to mucous membranes, it at first produces a tingling sensation, which is followed by anæsthesia of the parts to which it is applied. A beverage prepared from this drug by the natives produces a peculiar form of intoxication, characterized by great muscular weakness, drowsiness, and incoherent muttering. This drug has been employed in the treatment of diseases of the urinary tract, and is said to be of especial value in acute and chronic diarrhœa, acute cystitis, vaginitis, and leucorrhœa. It has also been tried in the treatment of nocturnal incontinence. Because of its irritating properties it cannot be employed as a local anæsthetic. The dose of the fluidextract is from 10 minims to 1 fluidrachm (0.6–4 Cc.), 3 or 4 times daily.

MEZEREUM, *U. S.*—Mezereum.

Mezerei cortex, Br.; *Cortex mezerei, Cortex thymeleæ* (or *coccognidii*).—*Mezereon bark, Dwarf-bay, Wild pepper, Spurge-flax* or *-olive, Magell*, E.; *Seidelbast, Kellerhals*, G.; *Mézéréon, Bois gentil, Garou sainbois*, Fr. Cod.; *Lauréole, Thymelée*, Fr.; *Timelea*, It.; *Macereon, Torviso*, Sp.; *Trovisco*, Port.

The dried bark of *Daphne Mezereum* L. and of other European species of *Daphne* (Fam. *Thymelæaceæ*).

Mezereum is official in most pharmacopœias, which differ greatly in the species named. *D. Gnidium* L. (*Thymelæa* G. All.), also called *Spurge-flax, Garou*, and *Sainbois*, is the principal species, next to that above named. *D. Laureola* L. (*Thymelæa L. Scop.*), the *Lady-* or *Wood-laurel*, is another species named by some pharmacopœias.

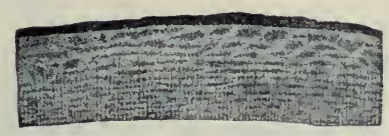
Fig. 274.

Mezereum (Nat.).

Origin.—All the above are slender, deciduous shrubs of mountainous or hilly regions, the flowers appearing before the leaves in earliest spring. The first named grows throughout most of Europe and extends into northern Asia, the others in southern Europe.

Description.—In long, thin, exceedingly tough bands, the edges fringed with partly detached bast-fibres, usually folded or rolled into disks; outer surface yellowish or reddish brown, smoothish and slightly lustrous, but with transverse scars and small blackish dots, or pale-greenish where this thin, easily detachable layer has been removed; inner surface whitish

Fig. 275.



Mezereon bark: transverse section, magnified.

or pale-green, silky, lustrous, very finely striate; bast in transverse layers, very tough; inodorous; taste very acrid.

Constituents.—The bark of Mezereum contains wax, acrid resin, yellow coloring-matter, an uncrystallizable and fermentable sugar, malic acid, and a bitter principle. A small amount of *daphnin* ($C_{15}H_{16}O_9.2H_2O$), an isomer of æsculin, occurs in the root-bark of *D. alpina* and *D. Gnidium*, and much more in the stem-bark. It is most abundant during flowering and fruiting.

Pharmaceutical Preparations.—Fluidextract of Mezereum, U. S. P.; Ointment of Mezereum, N. F.

Action and Uses.—When taken internally in overdose, mezereon acts as an acrid, narcotic poison, producing violent gastro-enteritis, with nausea, vomiting, and purging. If locally applied in the recent state, and allowed to remain sufficiently long, the drug produces vesication. When dry, the remedy is less active; but if it be moistened with vinegar and applied twice daily, vesication will eventually occur. Mezereon has been locally employed in the form of an ointment for the purpose of maintaining the discharge from cantharidal blisters, issues, and setons, and is said to be of value also as a stimulant to foul or ill-conditioned ulcers. It was formerly employed internally in the treatment of syphilitic, rheumatic, and scrofulous conditions, and was thought to be advantageous in chronic skin diseases. Its efficacy in these conditions is questionable, however, and at present it is rarely employed except in combination, for example, the compound decoction of sarsaparilla. Poisoning by mezereon should be treated by the prompt evacuation of the stomach and the administration of demulcent drinks, opium, and stimulants. The dose in powder is 10 grains (0.60 Gm.).

Allied Drugs.—Fructus (Grana) Mezerei, F. Gnidii, F. Coccognidii. *Mezereon fruit*, E.; *Kellerhalskörner*, G.; *Grains de garou*, Fr.—The berry-like fruit of the above species is in the fresh state red, or of the spurge-laurel blackish, globular-ovate or oval, about 5 Mm. ($\frac{1}{5}$ In.) thick; after drying, brown or black, wrinkled; contains a black glossy seed, is inodorous, and has a strongly acrid and burning taste. Besides gum, vegetable acids, protein compounds, and other medicinally unimportant principles, Casselmann obtained from the fruit 31 per cent. of drying oil, 0.22 per cent. of acrid resin, and 0.38 per cent. of *coccognin*, which differs from daphnin in having a neutral reaction, in being very sparingly soluble in hot water, and in not being a glucoside; when heated, it melts, and sublimes apparently unchanged, giving off a coumarin-like odor.

Daphne salicifolia Kunth grows in Mexico; the leaves, *Hojas del San Pedro*, are used for their epispastic properties.

Aloe-wood.—One of the sources of East Indian Aloe-wood is *Aquilaria Agallocha* Roxb., and perhaps other species of Aquilaria, of the family *Thymelæaceæ*.

MISTURA CREOSOTI, *Br.*—Creosote Mixture.

Mixture de créosote, Fr.; *Kreosotmixtur*, G.

Preparation.—Take of creosote, spirit of juniper, of each, 16 minims; syrup, 1 fluidounce; distilled water, a sufficient quantity. Shake the creosote with 14 fluidounces of the distilled water; add the syrup and the spirit of juniper, and sufficient distilled water to produce 16 fluidounces of the mixture.—Br.

This preparation is of practically the same strength as that of the 1885 Br. P., except that the glacial acetic acid has been omitted.

Uses.—This mixture is intended to allay vomiting. Dose, 1 fluidounce (30 Cc.).

MISTURA CRETÆ, *U. S., Br.*—Chalk Mixture.

Mixture avec la craie, Fr.; *Kreidemixtur*, G.

Preparation.—Take of compound chalk powder, 20 Gm.; cinnamon water, 40 Cc.; water, a sufficient quantity to make 100 Cc. Rub the compound chalk powder in a mortar with the cinnamon water and about 20 Cc. of water, gradually added, to a uniform mixture; transfer this to a graduated vessel, and rinse the mortar with sufficient water to make the product measure 100 Cc. Mix the whole thoroughly. This preparation should be freshly made when wanted.—U. S.

To prepare 4 fluidounces of chalk mixture will require 365 grains of compound chalk powder, 13 fluidrachms of cinnamon water, and sufficient water to make 32 fluidrachms.

Take of prepared chalk, $\frac{1}{4}$ ounce; tragacanth, in powder, 15 grains; refined sugar, $\frac{1}{2}$ ounce; cinnamon water, a sufficient quantity. Triturate the prepared chalk with the tragacanth and refined sugar, and gradually add sufficient cinnamon water to produce 8 fluidounces of the mixture.—Br.

This mixture spoils readily during warm weather; the addition of a little glycerin or the substitution of glycerin for the sugar, as recommended by G. W. Kennedy (1872), would tend to preserve it for several days while in the hands of the patient, but it should be dispensed only freshly made.

Uses.—Chalk mixture forms an agreeable method for the administration of chalk. It may be employed in the treatment of diarrhœa due to fermentation. Dose, from 1 to 4 fluidrachms (4–16 Cc.).

MISTURA FERRI COMPOSITA, *U. S., Br.*—Compound Iron Mixture.

Griffith's Mixture, E.; *Mixture de Griffith*, Fr.; *Griffithsche Eisenmixtur*, G.

Preparation.—Take of ferrous sulphate, in crystals, 6 Gm.; myrrh, in small pieces, 18 Gm.; sugar, 18 Gm.; potassium carbonate, 8 Gm.; spirit of lavender, 60 Cc.; rose water, a sufficient quantity to make 1000 Cc. Rub the myrrh, sugar, and potassium carbonate, in a mortar, with 700 Cc. of rose water, at first very gradually added, so that a uniform mixture may result. Transfer this to a graduated vessel, add the spirit of lavender, then the ferrous sulphate, previously dissolved in about 50 Cc. of rose water, and lastly sufficient rose water to make the product measure 1000 Cc. Mix the whole thoroughly. This preparation should be freshly made when wanted.—U. S.

Each fluidounce of this preparation contains about 3 grains of ferrous sulphate, 9 grains each of myrrh and sugar, 4 grains of potassium carbonate, $\frac{1}{2}$ fluidrachm of spirit of lavender, and $7\frac{1}{2}$ fluidrachms of rose water.

In the formula directed by the Br. P. the ingredients are ferrous sulphate, 25 grains; potassium carbonate, 30 grains; myrrh and refined sugar, each 60 grains; spirit of nutmeg, 50 minims; and rose water, 10 fluidounces (Imperial).

The preparation of this mixture presents no difficulty if good tears of myrrh are selected and the directions are strictly followed. The reaction between the iron and potassium salts, resulting in the formation of ferrous carbonate and potassium sulphate, takes place in the myrrh emulsion, by which the insoluble ferrous carbonate is kept in suspension. Unless in full and well-corked bottles, the mixture, at first of a dirty greenish color, is hardly protected against oxidation by the small quantity of sugar present, and should be freshly made when needed.

Uses.—Griffith's mixture is employed for the relief of the anæmia of tuberculosis, and is said to be useful in the treatment of chlorosis, and the menstrual disorders and nervous manifestations depending upon anæmia. It should not be administered if gastro-intestinal irritation or inflammation exists. Dose, from 1 to 2 fluidounces (30–60 Cc.).

MISTURA GLYCYRRHIZÆ COMPOSITA, *U. S.*—Compound Mixture of Glycyrrhiza.

Brown Mixture, E.; *Mixture de réglisse*, Fr.; *Lakritzenmixtur*, G.

Preparation.—Take of pure extract of glycyrrhiza, 30 Gm.; syrup, 50 Cc.; acacia, granulated, 30 Gm.; camphorated tincture of opium, 120 Cc.; wine of antimony, 60 Cc.; spirit of nitrous ether, 30 Cc.; water, a sufficient quantity to make 1000 Cc. Rub the pure extract of glycyrrhiza and acacia in a mortar with 500 Cc. of water until it is dissolved. Transfer the solution to a graduated vessel containing the other ingredients, and rinse the mortar with sufficient water to make the product measure 1000 Cc. Mix the whole thoroughly.—U. S.

Each fluidounce of "Brown Mixture" contains about 15 grains each of pure extract of glycyrrhiza and acacia, 25 minims of syrup, 1 fluidrachm of camphorated tincture of opium, 30 minims of wine of antimony, and 15 minims of spirit of nitrous ether.

The appearance of the finished product is unsightly and by no means in keeping with modern elegant pharmacy. The formula suggested by C. Tilyard in 1860 yields an equally efficient and far handsomer preparation: it prescribes a larger proportion of sugar (by no means a disadvantage), and can be still further improved upon by the use of purified extract of licorice, as now ordered by the Pharmacopœia. The formula as modified and adapted to the proportions of the Pharmacopœia is as follows: Dissolve 1 avoirdupois ounce of purified extract of glycyrrhiza in 10 ounces of water; add 4 fluidounces of camphorated tincture of opium, 2 fluidounces of antimonial wine, and 1 fluidounce of spirit of nitrous ether, and set the mixture aside for 12 or 24 hours with occasional agitation; filter the liquid into a bottle containing 3 fluidounces of mucilage of acacia and 20 avoirdupois ounces of granulated sugar, and wash the filter with sufficient water to bring the volume of the finished product up to 2 pints. The sugar is readily dissolved by agitation, and the result is a thin, rich-looking, clear syrup which keeps admirably.

Uses.—Brown Mixture is popularly employed as a cough mixture in the acute and subacute stages of bronchitis and laryngitis. It allays irritation, increases the activity of the bronchial and laryngeal mucosa, and thereby increases secretion, overcomes congestion, and promotes expectoration. The dose is from 1 to 4 fluidrachms (4–16 Cc.).

MISTURA GUAIACI, *Br.*—Guaiacum Mixture.

Mixture of Guaiac, E.; *Mixture de résine de gayac*, Fr.; *Guajakharzmixtur*, G.

Preparation.—Take of guaiacum resin, refined sugar, each ½ ounce; tragacanth, in powder, 35 grains; cinnamon water, 1 pint (Imperial measure). Triturate the guaiacum resin with the refined sugar and the tragacanth; add gradually the cinnamon water.—Br.

The preparation of the National Formulary differs from the above mainly in containing acacia in place of tragacanth. The formula is as follows: guaiac, in powder, and sugar, of each, 25 Gm.; acacia, in fine powder, 15 Gm.; cinnamon water, 1000 Cc. Triturate the powdered guaiac with the sugar and acacia, then gradually add the cinnamon water and mix thoroughly.—N. F.

Owing to the greater density of the British preparation, this mixture is less liable to separate than that of the National Formulary. Guaiac mixture should always be well agitated before using.

Uses.—For uses of guaiac mixture, see GUAIACI RESINA. Dose, from ½ to 1 ounce (16–30 Cc.).

MISTURA OLEI RICINI, *Br.*—Castor Oil Mixture.

Mixture d'huile de ricin, Fr.; *Ricinusoelmixtur*, G.

Preparation.—Take of castor oil, 3 fluidounces; mucilage of acacia, 1½ fluidounces; orange-flower water, undiluted, 1 fluidounce; cinnamon water, 2½ fluidounces. Mix the undiluted orange-flower water and the cinnamon water; place the mucilage of acacia in a mortar and to it add, alternately, in portions, the castor oil and the mixed waters, with constant trituration.—Br.

This preparation represents a 37.5 per cent. castor oil emulsion, but in accordance with the nomenclature of the Br. P. is designated as a mixture. Each fluidrachm contains 22.5 minims of castor oil.

Uses.—(See OLEUM RICINI.) Dose, from ½ to 2 fluidounces (16–60 Cc.).

MISTURA RHEI ET SODÆ, *U. S.*—Mixture of Rhubarb and Soda.

Potion à la rhubarbe alcaline, Fr.; *Alkalische Rhabarbermixtur*, G.

Preparation.—Take of sodium bicarbonate, 35 Gm.; fluidextract of rhubarb, 15 Cc.; fluidextract of ipecac, 3 Cc.; glycerin, 350 Cc.; spirit of peppermint, 35 Cc.; water, a sufficient quantity to make 1000 Cc. Dissolve the sodium bicarbonate in about 400 Cc. of water. Then add the fluidextracts, the glycerin, and the spirit of peppermint, and lastly, sufficient water to make 1000 Cc.—U. S.

To prepare 4 fluidounces of this mixture dissolve 64 grains of sodium bicarbonate in 14 fluidrachms of water, add 30 minims of fluidextract of rhubarb, 6 minims of fluidextract of ipecac, 12 fluidrachms of glycerin, 72 minims of spirit of peppermint, and, finally, sufficient water to make the volume as desired.

The mixture has a deep brown-red color.

Uses.—This preparation is employed as a carminative, antacid, and mild laxative. It may be given to children suffering with flatulent colic or fermentative diarrhœa. Dose to a child, from ½ to 1 fluidrachm (2–4 Cc.).

MISTURA SENNÆ COMPOSITA, *Br.*—Compound Mixture of Senna.

Black Draught, E.; *Mixture de séné composée*, Fr.; *Zusammengesetze Sennamixtur*, G.

Preparation.—Take of magnesium sulphate, 5 ounces; liquid extract of liquorice, 1 fluidounce; compound tincture of cardamoms, 2 fluidounces; aromatic spirit of ammonia, 1 fluidounce; infusion of senna, a sufficient quantity. Dissolve the magnesium sulphate in 10 fluidounces of infusion of senna; add the mixed liquid extract of liquorice, compound tincture of cardamoms, and aromatic spirit of ammonia; and sufficient infusion of senna to produce 1 pint (Imperial measure) of the compound mixture.—Br.

This preparation, officially designated as Black Draught, should not be confounded with the *compound infusion of senna* of the U. S. P., which is also known as *black draught* in this country. Not only do the two preparations differ in composition, but the British compound mixture of senna is also stronger than the U. S. compound infusion, containing about twice as much magnesium sulphate and one-fourth more senna.

The addition of compound tincture of cardamoms and aromatic spirit of ammonia materially improves the keeping qualities of the preparation and serves to correct the tendency to cause griping pains.

Uses.—This preparation has no advantages over INFUSUM SENNÆ COMPOSITUM (which see). Dose, from 1 to 1½ fluidounces (30–45 Cc.).

MISTURA SPIRITUS VINI GALLICI, *Br.*—Mixture of Brandy.

Brandy Mixture, E.; *Mixture de cognac*, Fr.; *Branntweinmixtur*, G.

Preparation.—Take of brandy, cinnamon water, each, 4 fluidounces; the yolks of 2 eggs; refined sugar, ½ ounce. Rub the yolks and sugar together, then add the cinnamon water and spirit.—Br.

In our opinion this preparation scarcely deserves a place in a pharmacopœia.

Uses.—This mixture forms an agreeable method for the administration of both stimulation and food in the various typhoid states. Dose, from 1 to 2 fluidounces (30–60 Cc.).

MORACEÆ.—The Mulberry Family.

This family, formerly regarded, together with the *Ulmaceæ* (Elm Family), as a division of the *Urticaceæ* (Nettle Family), comprises upward of 50 genera and about 900 species, of very diverse habit and appearance. Among them are the highly important food-plants Ficus (see FICUS and ELASTICA) and *Artocarpus*, or *Bread fruit*. From *Chlorophora tinctoria* (L.) Gaud. (*Morus t.* L.; *Maclura t.* D. Don) and *Maclura Brasiliensis* Endl. (*Broussonetia B.* Mart.) important dye-woods are obtained. Various rubber-yielding plants are considered under ELASTICA. *Brosimum galactodendron* Don (*Galactodendron utile* Kunth) is the *Cow-* or *Milk-tree*, *Palo de vaca* or *Arbol de leche*, of tropical America, the milk-juice said to be usable as is cows' milk. It contains, according to Boussingault, 58 per cent. of water and 42 per cent. of fixed matter, the latter consisting of wax and fat 32.2, sugar 2.8, proteids 1.7, salts 0.5, and undetermined substances 1.8 parts. The milk of *B. Alicastrum* Swz., of Jamaica, is acrid, though its seeds (*Bread-nuts*) are edible. The bast-fibers of many Moraceæ are tough and

are used in the manufacture of cordage and paper. The leaves of Morus are an important food for silk-worms. The poisonous and somewhat medicinal plant ANTIARIS has already been considered. The following, of minor importance medicinally, require brief mention:

MORUS is the fresh fruit of *Morus nigra* L., the *Black mulberry* (*Maulbeere*, G.; *Mures*, Fr.; *Mora*, Sp.), native of northeastern Europe and adjacent Asia, and largely cultivated. *Mori succus*, *Succus morarum*, *Mulberry-juice*, *Maulbeersaft* (G.), *Suc de mûres* (Fr.), or *Jugo del moras* (Sp.), is the juice of the ripe fruit, and is considerably used in medicine and pharmacy, though far less than formerly. The fruit is multiple, about 2.5 Cm. (1 In.) long and a third as thick, cylindraceous to oblong, purplish-black, fleshy, juicy, sweet, and edible. It consists of a great number of individual fruitlets, each a lenticular akene, enclosed in the fleshy calyx and crowned with a short filiform style. The juice is of a dark reddish-purple, nearly odorless, but sweet and acidulous. The analytical results, as obtained by Van Hees, were as follows, calculated for 100 parts of the fruit: sugar, 9.192, free acid (estimated as malic acid) 1.860, albuminous compounds 0.394, pectin, gum, and other organic compounds 2.031, ash 0.566, and water 84.707 parts, the remaining 1.250 parts consisting of the akenes and other tissues, with the insoluble inorganic compounds and ash. This composition varies much, as in all fleshy fruits, with the ripeness and other conditions. Except for its slightly laxative and expectorant qualities, mulberry-juice is to be regarded merely as an adjuvant, useful, in the form of a syrup, as a vehicle. The juice of the American *Black* or *Red mulberry* (*M. nigra* L.) may be substituted. It is less acid than the European, while that of *M. alba* L., the *White mulberry*, native of China, is sweet but rather insipid. The bark of the root of *M. nigra* is reputed anthelmintic. The root-bark of *M. Indica* Rumph. and other species, is much used in the Orient under the name *San-pai-p'i*, as a diuretic and expectorant, in hæmoptysis, etc.

CONTRAYERVA (*Bezoarwurzel*, *Giftwurzel*, G.; *Contrayerve*, Fr.) is the root of several species of *Dorstenia*, notably *D. Contrayerva* L. and *D. Brasiliensis* Lam., which have become famous in tropical America as antidotes to snake-bite. There is no reason to suppose that this repute rests upon any better basis than in the case of the immense number of others to which it applies. The root has 1 or 2 short annulate heads, is fusiform, about 12 Mm. (½ In.) thick, 50 or 75 Mm. (2 or 3 In.) long, and below divided into fine fibres; that of the second species is globular-ovate, about ¾ inch long, annulate, and beset with fine fibers. The color is reddish-brown, internally whitish. The bark is thick, with the inner portion of a punctate appearance, and encloses a brownish-yellow wood which is radiately marked by the medullary rays. The root has a rather unpleasant odor and a bitter and acrid taste. It contains the alkaloids *cajapine* and *contrayerbine*, volatile oil, resin, gum, free acid, starch, etc. The drug is an aromatic, with slight bitter qualities, and is hence mildly beneficial as a stomachic and stimulant. The dose is about 30 grains (2 Gm.).

ARTOCARPUS INCISA L. is indigenous to the Moluccas and the islands of the southern Pacific. The nearly ripe pistillate inflorescence, known as *Bread-fruit*, forms a globular sorosis about 15 Cm. (6 In.) in diameter, and consists of a mealy and spongy receptacle in which the oblong angular akenes are imbedded. A similar product, known as *Jack-fruit*, is yielded by *Artocarpus integrifolia* L.; it is nearly pear-shaped, and is largely used in India and the East Indian islands.

BICHETEA OFFICINALIS Heerm., of Brazil, is one of the domestic antisyphilitic drugs to which the names *Murure* and *Mercurio vegetal* have been applied. The milk-juice is employed. The milk-juices of various species of *Cecropia* are similarly employed. That of *C. peltata* L. is used in Paraguay as a digitalis-substitute, and contains the alkaloid *cowleyine*. *Streblus asper* Lour. (*Trophis a.* Roxb.), of Java, contains a poison which acts like that of *Antiaris*.

MORPHINA, *U. S.*—Morphine.

Morphia, *Morphinum*.—*Morphia*, E.; *Morphine*, Fr.; *Morphium*, *Morphin*, G.

Formula, $C_{17}H_{19}NO_3 + H_2O$ or $C_{17}H_{17}(OH)NO.OH + H_2O$. Molecular weight, 300.92.

Morphine is the principal alkaloidal constituent of opium, in which it occurs both as sulphate and meconate. It is said to be present in several members of the *Poppy* family, but is particularly found in the capsules of *Papaver somniferum* L. just before maturity. The statement of Charbonnier, that morphine is present in *Argemone mexicana* L., has been shown by Schlotterbeck (*Proc. Am. Pharm. Assoc.*, 1901, p. 247) to be erroneous.

Morphine was the first alkaloid known. It was separated by Derosne (1803) from concentrated infusions of opium by precipitation with ammonia, but mistaken for narcotine. Sertürner (1816) finally established the identity of morphine and proved its basic nature as well as its poisonous effects. Chemically morphine is a phenanthrene derivative containing two hydroxyl groups, one of phenolic, the other of alcoholic character.

Preparation.—Morphine for commercial purposes may be obtained in several ways, and it is probable that manufacturers, in each case, follow some favorite economical

process. The method of Staples, which was adopted in the U. S. P. of 1870, consists in exhausting opium by repeated maceration with cold water, concentrating the mixed infusions, filtering, adding alcohol and ammonia water, and finally setting the liquid aside to allow crystals to form, which latter after removal by filtration are dissolved in hot alcohol, treated with animal charcoal and the solution again allowed to crystallize.

The Gregory-Anderson method, originated by Robertson and recognized in the Br. P. of 1885, directs the exhaustion of opium with cold water, after which the united liquids are concentrated, strained through calico and mixed with calcium chloride, whereby the alkaloids are kept in solution as hydrochlorides, while meconic acid, coloring-matter and other constituents are precipitated as calcium compounds. After filtration, the liquid is concentrated and yields a crystalline mass of morphine and codeine salts, narcotine and other bases remaining in the dark-colored mother-liquors. The crystals are purified by re-solution in water, boiling with animal charcoal, and final recrystallization. The purified salts are dissolved in hot water and the solution mixed with ammonia water, which precipitates the morphine and retains the codeine in solution. The morphine may be subsequently recrystallized from alcohol.

Merck's process consists in precipitating a concentrated infusion of opium by means of sodium carbonate. The precipitate is washed with water and treated with alcohol, whereby the less important alkaloids are removed together with resinous and coloring-matters. The crude morphine remaining is expressed and dissolved in a slight excess of diluted acetic acid, whereby it is freed from narcotine, which latter does not combine with the acid and remains undissolved. After filtration through animal charcoal the acetous solution is precipitated with ammonia water, the finely crystalline morphine being collected on a strainer and washed with cold water and dried.

Properties.—Morphine occurs in short, transparent, colorless or white, inodorous rhombic prisms or fine needles, or as a crystalline powder, permanent in the air, and having a bitter taste. It contains 1 molecule (5.94+ per cent.) of water of crystallization, which it gradually loses at 75° C. (167° F.), becoming completely anhydrous if heated for 4 hours at 100° C. (212° F.). When heated to about 200° C. (392° F.) it turns brown, and melts at 254° C. (489.2° F.) to a black liquid, some of the alkaloid volatilizing undecomposed.

The solubility of morphine depends much upon whether it is in a crystalline, amorphous, or nascent condition. Crystalline morphine is soluble at 15° C. (59° F.) in 4350 (5000, Hager, Schmidt) parts of water, 300 parts of alcohol, 100 parts of absolute alcohol, 6148 parts of ether (Prescott, 1250 parts Schmidt, 1300 parts Hager), 4379 parts of chloroform (Prescott), 1700 parts of acetic ether (Hager, 1665 parts Schmidt). Prescott has found that the amorphous alkaloid requires only about one-third, and the alkaloid in the nascent condition about one-fifth as much ether or chloroform for solution as the crystalline variety. Morphine is also soluble at 15° C. (59° F.) in 8930 parts of benzene (Prescott, insoluble U. S. P.), 91 parts of amyl alcohol (Prescott) (113.5 parts at 25° C. (77° F.), U. S. P.), 4.75 parts of 80 per cent. chloral hydrate solution, 220 parts of glycerin, 3125 parts of carbon tetrachloride, or 117 parts of 10 per cent. ammonia water. At 25° C. (77° F.) morphine requires for solution 3330 parts of water, 168 parts of alcohol, 4464 parts of ether, 1800 parts of chloroform or 525 parts of acetic ether (U. S. P.); at 80° C. (176° F.), 1040 parts of water (U. S. P.); at 60° C. (140° F.), 76 parts of alcohol (U. S. P.); at 100° C (212°), 500 parts of water (Schmidt). Boiling alcohol dissolves $\frac{1}{36}$ of its weight, and boiling absolute alcohol $\frac{1}{18}$ of its weight of morphine (Schmidt). Morphine is insoluble in oil of anise (means of separation from codeine), but dissolves in aqueous solutions of the fixed alkali hydroxides and in 100 parts of lime water, forming morphinates of the respective bases. The alkaloid is precipitable from these solutions by carbon dioxide, as well as ammoniacal salts. The alkaline solutions on exposure to air are gradually oxidized, turning brown, and developing pseudo- or oxydimorphine; the same changes occur when aqueous solutions are boiled with exposure to air. Morphine is a strong base and reducing agent. Its aqueous solution is strongly alkaline to litmus and curcumin. It forms crystallizable salts with acids. Solutions of morphine and its salts are strongly lævorotatory, the rotation depending much upon the nature of the solvent. In alcoholic solution the specific rotation has been found to be $[\alpha]_D = -70°$. Morphine gives numerous color reactions, which are usually obtained by adding the reagent to a minute crystal of morphine, or to the residue left upon a porcelain surface by evaporation of a solution of morphine in alcohol or amyl alcohol,

In using the latter solvent, the amyl alcohol should be previously distilled and tested to avoid misleading results.

Concentrated sulphuric acid, free from nitric acid, dissolves morphine without color, but upon heating a dark-brown color is produced. If a crystal of potassium nitrate be added to the solution, a light or dark-brown color is produced, depending on the amount of alkaloid employed. (Codeine under like conditions gives a green color, changing to brown, while narcotine produces a cherry-red color.) Nitric acid alone dissolves morphine with an orange to reddish-yellow color, gradually fading to yellow. If morphine be dissolved in concentrated sulphuric acid and the solution heated to near 150° C. (302° F.), the addition of a little nitric acid produces a violet-blue color, changing quickly to blood-red, and afterward to deep orange (Husemann, 1863). Other oxidizing agents, such as chlorine or chlorates, may be used in place of nitric acid, in the Husemann test, with equally good results. Mixed with 6 to 8 times its weight of sugar, morphine acquires with sulphuric acid a bright-purple-red color, gradually changing to violet-blue, blue-green, and dingy-yellow (Schneider, 1872), the delicacy of the reaction being increased by the addition of a little bromine water, so that 0.00001 Gm. still shows a rose-red color (Weppen, 1874). Morphine mixed with about 8 times its weight of hydrastine acquires with concentrated sulphuric acid a violet-blue color (Lloyd, 1900). With Fröhde's reagent (0.001 to 0.005 Gm. of sodium molybdate in 1 Cc. of concentrated sulphuric acid) morphine acquires a violet color, changing to blue, olive-green, yellow, and in 24 hours to purplish-blue. If the morphine be dissolved in concentrated sulphuric acid, the solution heated, and Fröhde's reagent then applied, a green color appears, which on the addition of a minute fragment of potassium nitrate changes to a red color (G. Bruylants). Morphine dissolved in concentrated sulphuric acid containing formaldehyde (2 drops of 40 per cent. solution to 3 Cc. of sulphuric acid) produces a fine violet to almost blue coloration (Marquis, 1900). Mecke's reagent (0.5 Gm. of selenous acid in 100 Cc. of concentrated sulphuric acid) or Lafon's reagent (1 Gm. of ammonium selenite in 20 Cc. of concentrated sulphuric acid) dissolves morphine with a bluish color, changing through blue to an intense green or olive-green, and on heating, to brown. (If codeine be added to sulphuric acid containing a little selenous acid, a green color is produced, which changes to blue and back again to green, the green color caused by narcotine under the same conditions changing to brown and then to cherry-red.) A brownish-red to violet color is produced when titanic acid is added to a solution of morphine in concentrated sulphuric acid (Flückiger). When morphine is dissolved in a few drops of a 5 per cent. aqueous solution of sulphuric acid, a little lead dioxide added to the solution and the mixture stirred for a few minutes, the clear liquid drawn from the same, upon the addition of ammonia produces an immediate brown color (G. Fleury, 1901). Ehrlich's reagent (1 Gm. of sulphanilic acid dissolved in water containing 50 Cc. of hydrochloric acid and diluted to a liter; when required, 10 Cc. of the solution are mixed with 2 Cc. of a 0.5 per cent. solution of sodium nitrite and the mixture added drop by drop to the solution to be tested) produces in an ammoniacal solution of morphine a wine-red coloration (*Jour. Chem. Soc.*, 1900, ii. p. 776). A few drops of a 20 per cent. solution of benzaldehyde in absolute alcohol added to a trace of the alkaloid on a porcelain surface, followed by a drop of concentrated sulphuric acid, dissolves morphine with the production of red to yellowish-red streaks (H. Melzer, *Fres. Zeitschr. anal. Chem.*, 1898, pp. 747, 748). The addition of 5 per cent. sodium phosphomolybdate solution causes a yellow precipitate in morphine solutions, which is soluble in ammonia water. Morphine decomposes iodic (Sérullas) and periodic (Boedeker) acids, liberating iodine; in dilute solution the addition of a little sulphuric acid is advisable; the red (or yellow in dilute solutions) color developed is intensified by the addition of ammonia (M. Lefort). If a solution of morphine be mixed with a solution of starch and evaporated on a porcelain surface at a gentle heat, and the residue after cooling be moistened with iodic acid, the presence of $\frac{1}{20000}$ of a grain of morphine will produce a blue color (A. Dupre). An equally satisfactory application of the iodic acid test is to shake a dilute solution of iodic acid, or iodate, slightly acidulated with sulphuric acid, with chloroform. If the chloroform remains uncolored, the solution of morphine to be tested is then added and the mixture again shaken, when in the presence of morphine the chloroform layer will turn pink through the liberated iodine. Solutions of silver nitrate, gold chloride, potassium ferricyanide, ammonio-cupric sulphate, and chromic acid, are reduced by morphine and its salts. Dilute solutions of ferric chloride give a blue color with morphine,

A blue precipitate is produced when a few drops of a 10 per cent. solution of ferric chloride are added to a solution of morphine, followed by a few drops of a fresh 1 per cent. solution of potassium ferricyanide. Subjected to the action of the electric current, morphine is converted into pseudomorphine (also known as oxydimorphine or dehydromorphine), which see under constituents of Opium. Morphine is rapidly oxidized by potassium permanganate, and this oxidizing action has been studied by C. W. Johnson (*Proc. Am. Pharm. Assoc.*, 1903), who found that when a solution of 0.5 Gm. of the permangauate is added to a solution of 1 Gm. of morphine hydrochloride, instantaneous reaction ensues, the color of the liquid changing to mahogany-brown, while manganese dioxide is precipitated, nearly all the morphine being converted into pseudomorphine. With the use of increasing quantities of the permanganate, oxidation continues, the color of the liquid gradually changing to straw-yellow, while the newly formed pseudomorphine disappears and alkali oxalate is found in solution.

Tests.—Sulphuric acid containing a crystal of potassium dichromate imparts to morphine no color at first, but after a time a green color appears (absence of strychnine, which gives a purple color, or of acetanilide, which gives a crimson color, changing to green). If 0.1 Gm. of morphine be dissolved in 10 Cc. of diluted hydrochloric acid, no red coloration should be produced by the addition of a few drops of ferric chloride test-solution (absence of meconic acid or meconates). If to a neutral 1 per cent. solution of morphine made by the careful addition of dilute sulphuric acid, a few drops of ferric chloride test-solution be added, a blue color will be produced, which is destroyed by acids, alcohol, or heating. On adding 4 Cc. of potassium hydroxide test-solution to 0.2 Gm. of morphine, a clear colorless solution, free from any undissolved residue, should result (absence of and difference from various other alkaloids), and no odor of ammonia should be noticeable.—U. S. The salts of morphine are precipitated from their solutions by the alkalies and alkaline earths, the precipitates being soluble in an excess of the precipitant. Similar precipitates are produced by the alkali carbonates and cyanides, but the alkali bicarbonates fail to precipitate acid solutions in the cold. Tannin causes a white precipitate soluble in acetic acid, in mineral acids, and in alcohol. Auric or platinic, but not mercuric, chloride occasions a yellow precipitate. Codeine causes a precipitate of morphine in the solution of the salts. The acidulated solutions of morphine are precipitated by potassio-mercuric iodide, potassio-cadmium iodide, and other general reagents for alkaloids; the precipitate with phosphomolybdic acid turns blue with cold sulphuric acid and brown on warming. 1 Cc. of Mayer's test-solution precipitates 0.020 Gm. morphine. When a salt of morphine is heated with an excess of sulphuric or hydrochloric acid to near 150° C. (302° F.), the alkaloid parts with H_2O and is converted into apomorphine, $C_{17}H_{17}NO_2$ (see p. 206).

Pharmaceutical Preparation.—Solution of Morphine Citrate, N. F.

Action and Uses.—Morphine is rarely employed as morphine, but when combined with acids it forms soluble salts which are largely used. It is the principal narcotic alkaloid of Opium (which see), and its action is closely allied to that of the latter drug. This alkaloid possesses the sudorific, soporific, and anodyne properties of opium, but it is less liable to produce the constipation and other untoward effects which frequently follow the administration of the crude drug. The salts of morphine are usually employed either internally by the stomach or hypodermically. The symptoms and treatment of poisoning by this drug are identical with those of opium. The dose is from $\frac{1}{8}$ to $\frac{1}{2}$ grain (0.008–0.03 Gm.).

Unofficial Salts of Morphine.—Among the unofficial salts of morphine used at different times may be mentioned Morphine Benzoate, M. Borate, M. Citrate, M. Lactate, M. Oleate, M. Stearate, and M. Valerianate. They may be prepared by neutralizing the respective acids in alcoholic or aqueous solution (as may be necessary) with pure morphine and crystallizing the resulting solution or evaporating same to dryness. Morphine oleate is generally employed in the form of solution in excess of oleic acid, prepared by dissolving the desired quantity of pure morphine, 2, 4, or 5 parts, in 98, 96, or 95 parts of oleic acid by aid of a water-bath.

Derivatives of Morphine.—Dionin. *Ethylmorphine hydrochloride.* $C_{17}H_{18}NO_3C_2H_5HCl+H_2O$.—When ethyl iodide is made to act on morphine in an alkaline solution, ethylmorphine, also known as codethyline, $C_{17}H_{17}NO(OH)OC_2H_5$, is formed, a base, which when pure melts at 93° C. (199.4° F.). By neutralizing the newly formed base with hydrochloric acid, the salt commercially known as *dionin* is obtained. Dionin occurs as a crystalline powder, soluble in about 7 parts of water at 15° C. (59° F.) and in an equal weight of alcohol, but nearly

insoluble in ether and chloroform. Its aqueous solutions are precipitated by the usual alkaloidal reagents. If 0.10 Gm. of dionin be dissolved in 10 Cc. of pure sulphuric acid, a colorless liquid results, which upon addition of a drop of ferric chloride solution assumes a violet or blue color; the further addition of 2 or 3 drops of nitric acid changes the color to deep red. Dionin may be distinguished from morphine salts by not causing a blue coloration immediately when added to ferric chloride solution containing some potassium ferricyanide; a bluish-green color is gradually developed. Dionin possesses the narcotic properties of opium to a very limited degree, and has been used in phthisis and other pulmonary affections to allay excessive cough. As it possesses local anæsthetic powers it has also been employed in cases of corneal ulcer, glaucoma, and iridocyclitis. For these purposes it is employed in 5 per cent. solutions, and the anæsthesia lasts about 24 hours. DeSchweinitz has not found it satisfactory. Dose, ¼ to ½ grain (0.015–0.025 Gm.).

HEROINE. *Diacetyl-morphine.* $C_{17}H_{17}NO(C_2H_3O_2)_2$. (See HEROINÆ HYDROCHLORIDUM.)—Heroine has been employed as a substitute for morphine for the purpose of allaying excessive cough. Unlike the latter remedy it acts as a respiratory stimulant and does not produce constipation or stupor. It should be given in doses of from $\frac{1}{20}$ to $\frac{1}{5}$ grain (0.003–0.01 Gm.), several times daily.

PERONIN. *Benzyl-morphine hydrochloride.* $C_{17}H_{18}NO_3(C_6H_5CH_2)HCl$.—If benzyl chloride be allowed to act on morphine, hydrochloric acid is split off, which unites with the newly formed benzyl-morphine, producing a white salt to which the name *peronin* has been given. The compound is soluble in water and in diluted alcohol, more readily when warmed, but is insoluble in ether and chloroform.

MORPHINÆ ACETAS, *U. S., Br.*—Morphine Acetate.

Morphiæ acetas, Morphinum (s. Morphium) aceticum. Acetate of morphia, E.; *Acétate de morphine,* Fr.; *Morphinacetat, Essigsaures Morphium,* G.

Formula, $C_{17}H_{19}NO_3HC_2H_3O_2 + 3H_2O$. Molecular weight, 396.26.

Preparation.—Freshly precipitated morphine, while still moist, is diffused in water, dissolved by neutralizing with acetic acid, the solution evaporated on a water-bath until it concretes on cooling, and the mass dried with a gentle heat and reduced to powder. A very slight excess of acetic acid is rather of advantage, since the salt begins to decompose during the evaporation by liberation of acid. The salt may be crystallized with some difficulty in the form of white silky needles, but is very generally obtained in powder as directed above.

For giving the salt a very handsome appearance, Hager gives the following directions: Rub 10 parts of pure morphine into powder, keeping it moist by the addition of a little alcohol, and add 25 parts of glacial acetic acid, triturating constantly; then drop alcohol into the mixture until it has become of syrupy consistence, and afterward ether until the color of the mixture has changed to milk-white; after 2 or 3 days the solidified mass is loosened in the mortar and turned, and when completely dry is rubbed into powder and preserved.

The U. S. P. directs the salt to be kept in well-stoppered dark-amber-colored vials, together with a minute quantity of acetic acid.

Properties.—Morphine acetate forms a white or faintly yellowish, crystalline or amorphous powder which has a slight acetous odor and a very bitter taste. It is soluble at 15° C. (59° F.) in 2.5 parts of water (Br.; in 12 parts Hager), in about 100 parts of 90 per cent. alcohol (Br.; in 30 parts Hager); at 25° C. (77° F.) in 2.25 parts of water, 21.6 parts of alcohol, 5.2 parts of glycerin, or 480 parts of chloroform (U. S.); at 60° C. (140° F.) in 2.5 parts of alcohol (U. S.); at 80° C. (176° F.) in 2 parts of water (U. S.). The salt is also soluble in 3 parts of boiling water (Hager), but is insoluble in ether (U. S.), and when exposed to air gradually loses acetic acid. When heated, the salt loses water and acetic acid, and melts at 200° C. (392° F.). An alcoholic solution of morphine acetate, mixed with an excess of ether, deposits crystals of morphine, free acetic acid remaining in solution. Cold strong sulphuric acid dissolves the salt without color only when recently made. When kept on hand, it slowly loses acetic acid; its reaction to test-paper changes from neutral to alkaline, and the salt becomes incompletely soluble in water unless a little acid be added; it gradually acquires a yellowish-gray, and finally brownish, color, and should then be redissolved in acetic acid and evaporated or converted into another salt of morphine. Its aqueous solution undergoes similar changes, the acetic acid being slowly decomposed, with the

separation of brown flocculent compounds, while the morphine crystallizes out, forming long prisms if the solution is not disturbed.

Tests.—The salt responds to the reactions and tests described above under MORPHINA and leaves no residue when ignited. If its solution is precipitated by tannin, the addition of dilute hydrochloric acid redissolves the precipitate; solution of potassium or sodium hydroxide gives a white precipitate soluble in excess of the alkali; a remaining turbidity would indicate the presence of narcotine. Sulphuric acid added to the salt liberates acetous vapors. "2 Gm. of the salt form with 6 Cc. of warm morphinated water a slightly turbid solution, which is rendered clear by the addition of 0.1 Cc. of acetic acid; and this solution, when mixed with solution of ammonia in excess, yields a precipitate which, after washing and drying as described under MORPHINÆ HYDROCHLORIDUM, weighs 1.42 Gm. If the salt yield a larger proportion of morphine than this, it should be recrystallized from hot water acidulated with acetic acid."—Br.

Pharmaceutical Preparation.—SOLUTION OF MORPHINE ACETATE, Br. P.

Action and Uses.—See MORPHINA. Dose from $\frac{1}{8}$ to $\frac{1}{2}$ grain (0.008–0.03 Gm.).

MORPHINÆ HYDROCHLORIDUM, *U. S., Br.*—Morphine Hydrochloride.

Morphinum Hydrochloricum, P. G.; *Morphiæ hydrochloras, Morphiæ murias.*—*Muriate of morphia*, E.; *Chlorhydrate de morphine*, Fr.; *Morphinhydrochlorid, Salzsaures Morphium*, G.

Formula, $C_{17}H_{19}NO_3HCl + 3H_2O$. Molecular weight, 372.86.

Preparation.—Diffuse pure morphine in boiling distilled water placed in a porcelain capsule kept hot, and add, constantly stirring, the diluted hydrochloric acid, proceeding with caution, so that the morphine may be entirely dissolved and a neutral solution obtained. Set aside to cool and crystallize. Drain the crystals, and dry them on filtering-paper. By further evaporating the mother-liquor and again cooling additional crystals are obtained. If pure morphine has been used and an excess of hydrochloric acid avoided, the salt may be wholly obtained in crystals by judicious evaporation of the mother-liquor. On account of the greater stability of this salt and of its solution, the German Pharmacopœia directs it to be dispensed whenever morphine acetate is prescribed.

Properties.—Morphine hydrochloride crystallizes in white, silky, flexible, and inodorous needles or minute, colorless, cubical crystals having a bitter taste and neutral reaction. It is soluble in 24 parts (Br.) (25 parts P. G.) of cold water, or 1 part of boiling water (Br.), or 50 parts of cold alcohol (Br., P. G.); at 25° C. (77° F.), in 17.2 parts of water or 42 parts of alcohol (U. S.); at 60° C. (140° F.) in 35.5 parts of alcohol (U. S.); at 80° C. (176° F.) in 0.5 part of water (U. S.). It is said to be soluble in 19 parts of glycerin or 800 parts of olive oil, but is insoluble in ether and chloroform. Heated to 100° C. (212° F.) the salt loses all of its water of crystallization (14.38+ per cent.), and when heated to 250° C. (482° F.) it begins to turn brown, and on higher heating chars without melting. On shaking an aqueous solution of the salt with ammonium chloride and diluted ammonia water, a crystalline precipitate is formed, which should respond to all tests and reactions given under MORPHINA. The color tests for the identification of morphine hydrochloride and those showing the absence of impurities are identical with those described under MORPHINA.

Tests.—The salt should not have an acid reaction, and should answer to all the morphine reactions and tests described before; its aqueous solution yields with silver nitrate a white precipitate, which is insoluble in nitric acid, but dissolves in ammonia. With solution of potassium or sodium hydroxide it should yield a precipitate soluble in excess of alkalies and corresponding to the tests for morphine. When ignited, the salt should leave no fixed residue. Heated on a water-bath for 10 or 15 minutes with a few drops of sulphuric acid, cooled, and treated with a few drops of diluted nitric acid, it gives a violet color rapidly passing to blood-red. It dissolves without coloration in strong sulphuric acid; the addition of a small quantity of sodium arsenate to a portion of this solution causes a bluish-green coloration, and a small quantity of bismuth oxynitrate added to another portion gives a purplish-brown coloration. "2 Gm. of morphine hydrochloride dissolved in 250 Cc. of warm morphinated water, with solution of ammonia added in the slightest possible excess, will give on cooling a crystalline precipitate which, when washed with a little cold morphinated water and dried, should weigh 1.51 Gm.

The drying should be accomplished, first by pressing the precipitate between sheets of bibulous paper, then by exposing it to a temperature from 55° to 60° C. (131°–140° F.), and finally to a temperature of 110° C. (230° F.) for 20 minutes."—Br. 5 Cc. of an aqueous solution of morphine hydrochloride (1 : 30) give upon the addition of a drop of solution of potassium carbonate, either immediately or after a few seconds, a pure white crystalline precipitate, which should not discolor on exposure to air, nor color chloroform reddish when chloroform is shaken with the same (absence of apomorphine, U. S., P. G.). Upon adding a drop of solution of ammonia to 5 Cc. of an aqueous solution of morphine hydrochloride (1 : 30) a pure white crystalline precipitate should form, which is readily soluble in aqueous sodium hydroxide solution. When the latter solution is shaken with an equal volume of ether, the ether after complete separation and evaporation of the ethereal layer should not leave a weighable residue.—P. G.

Pharmaceutical Preparation.—Solution of Morphine Hydrochloride, Br. P.

Action and Uses.—See Morphina. Dose from $\frac{1}{8}$ to $\frac{1}{2}$ grain (0.008–0.03 Gm.).

MORPHINÆ SULPHAS, *U. S.*—Morphine Sulphate.

Morphinum sulphuricum, Morphiæ sulphas.—Sulphate of morphia, E.; *Sulfate de morphine*, Fr.; *Morphinsulfat, Schwefelsaures Morphium*, G.

Formula, $(C_{17}H_{19}NO_3)_2H_2SO_4 + 5H_2O$. Molecular weight, 752.83.

Preparation.—This salt may be prepared in the same manner as the hydrochloride. 1 ounce of pure morphine is diffused in 2 ounces of boiling distilled water, and diluted sulphuric acid is cautiously added until the alkaloid is dissolved and the liquid has a neutral reaction to test-paper; it is then allowed to cool and crystallize; the crystals are drained and dried, and the mother-liquor concentrated to obtain an additional crop of crystals.

Properties.—Morphine crystallizes in white fascicles of transparent, silky, inodorous, and bitter needles, which are neutral to test-paper, and are not altered on exposure to air. At 100° C. (212° F.) it parts with 3 molecules of water (7.12+ per cent.), but on being heated to 130° C. (266° F.) it loses the remaining 2 molecules (4.75+ per cent.) (U. S.). According to Hager, the crystals part with their water more readily, losing some on exposure at 30°–40° C. (86°–104° F.), and all of it at 100° C. (212° F.). The official salt dissolves at 15° C. (59° F.) in 20 parts of water or 702 parts of alcohol; at 25° C. (77° F.) in 15.3 parts of water or 465 parts of alcohol (U. S.); at 60° C. (140° F.) in 187 parts of alcohol (U. S.); at 80° C. (176° F.) in 0.6 part of water (U. S.). It is said to be soluble in 144 parts of boiling alcohol, but is insoluble in ether and chloroform. Its aqueous solution is neutral to test-paper and yields a white precipitate with barium chloride insoluble in nitric acid. On heating the salt to 250° C. (482° F.) it turns brown and chars, but does not melt; upon ignition it burns without residue.

Tests.—Upon adding dilute solutions of ammonium chloride and ammonia to an aqueous solution of morphine sulphate, a precipitate results which, when filtered off and washed, should respond to all the reactions and tests mentioned under Morphina (U. S.).

Pharmaceutical Preparations.—Compound Morphine Powder, U. S. P.; Hypodermic Solution of Morphine, Compound Syrup of Morphine, Syrup of Morphine Sulphate, N. F.

Action and Uses.—See Morphina. Dose from $\frac{1}{8}$ to $\frac{1}{2}$ grain (0.008–0.03 Gm.).

MORPHINÆ TARTRAS, *Br.*—Morphine Tartrate.

Morphinum tartaricum.—Tartrate de morphine, Fr.; *Morphintartrat, Weinsaures Morphium*, G.

Formula, $(C_{17}H_{19}NO_3)_2C_4H_6O_6 + 3H_2O$. Molecular weight, 768.64.

Morphine tartrate may be prepared by the combination of morphine and tartaric acid in molecular proportions.—Br.

On dissolving 4 parts of morphine with 1 part of tartaric acid in 15 parts of hot water, the greater part of the salt crystallizes in small needles on cooling. The Br. P. describes morphine tartrate as "A white powder consisting of fine nodular tufts of minute acicular crystals. Efflorescent at 20° C. (68° F.). Soluble in 11 parts of cold water, almost insoluble in alcohol (90 per cent.). 2 Gm. dissolved in 20 Cc. of warm morph-

inated water, with solution of ammonia added in the slightest possible excess, will give, on cooling, a crystalline precipitate which, after washing and drying as described under MORPHINÆ HYDROCHLORIDUM, should weigh 1.47 Gm." The salt represents 78.3 per cent. of crystallized morphine. This salt was introduced on account of its greater solubility in water, and therefore is more suitable for hypodermic injections than the other salts of morphine.

Pharmaceutical Preparation.—SOLUTION OF MORPHINE TARTRATE, Br. P.

Action and Uses.—See MORPHINA. Dose $\frac{1}{8}$ to $\frac{1}{2}$ grain (0.008–0.03 Gm.).

MOSCHUS, *U. S., Br.*—Musk.

Moschus orientalis, M. Chinensis, M. Tibetanus; Musc, Fr. Cod.; *Chinese, Thibet, or Tonquin musk*, E.; *Moschus*, G.; *Muschio*, It.; *Almizell, Almizole*, Sp.; *Almiscar*, Port. The dried secretion from the preputial follicles of *Moschus moschiferus* L. (Ord. *Ruminantia*).

Musk is official in nearly all pharmacopœias.

Origin.—The general appearance of the musk-deer is that of a very small deer, but it is hornless and has long, downwardly projecting canine teeth. It inhabits chiefly the mountainous regions and elevated table-lands of Central Asia, and is met with from Anam, in Farther India, northwestward to Thibet, and northward in China and Tartary to Manchuria and southern Siberia. It lives in pine forests in the Himalayas, frequently at an altitude of 3000–4260 M. (10,000 to 14,000 Ft.). The musk-sac is found in the male only, and is located on the abdomen, immediately before the preputial orifice and to the rear of the umbilicus. The animal has nocturnal habits and is taken by snares and pit-falls, or sometimes by shooting; the sac is cut off as soon as possible, and rapidly dried by pressing it against heated stones. It is usually imported in small boxes, lined with sheet lead and containing about 25 sacs, each wrapped in paper. The outer hairs are trimmed short, and are of a yellowish or grayish color. Musk enters commerce through Chinese ports. Musk should be kept in not too warm a place, and where the air can have some access to it.

FIG. 276.

Musk-deer.

Description.—The musk-bag (called sac, pod, or pouch) is oval in shape, about 5 Cm. (2 In.) long and 38 Mm. (1½ In.) wide, with a thickness of about 13 Mm. (½ In.); upper surface smooth and flat, the lower convex and hairy; hairs grayish and brown, rather stiff and appressed, arranged in a circle toward the aperture near the center of the bag, and in the form of a pencil toward the preputial orifice, which is about 6 Mm. (¼ In.) in the rear of the former; extending from this orifice, underneath the hairy skin between the strata of the muscular coat and toward the posterior end of the sac, is a canal containing the front portion of the thin penis; following the muscular coat, the musk-pouch proper, with an external fibrous coat, having on the inner surface numerous depressions resembling meshes and surrounded by folds, and covered by two coats—the one soft and pearly, and the other very delicate, silvery-white on the outside, and yellowish or brownish on the inside. The musk is supposed to be separated by a number of glands, of which two or more are situated in each depression. In the young animal the secretion is slight and of a milky appearance, but after it has passed its third year the musk is of better quality; in the fresh state it is of an unctuous consistence. The average weight of musk-bags is about 394 grains, and of the contained musk about 157 grains, according to Cramer and Small. The Swiss and Italian pharmacopœias require each sac to yield from 10 to 30 Gm. of musk, the Russian 15 to 40 Gm., and the latter rejects sacs which do not yield 50 per cent. of good musk.

FIG. 277.

Chinese musk-sac.
Lower surface. Upper surface.

Musk is of a crummy appearance, near the musk-orifice mixed with grayish hairs of a

reddish-brown color or darker brown, and irregularly granular, somewhat unctuous to the touch, of a strong, diffusible, and persistent odor, and of a bitterish taste. When entirely exsiccated it is almost inodorous, but the odor reappears on moistening, and is increased by the addition of a little alkali. The odor disappears or is more or less modified on triturating the musk with camphor, oil of bitter almond, fennel, ergot, mustard, sulphur, acids, various salts, etc.

Other Varieties, Substitutes, and Adulterants.—*Siberian musk* comes by way of St. Petersburg, hence the name *Russian musk;* it often resembles and has the same quality as the preceding; when in flatter ovate sacs with thinner and paler hairs, and of fainter, less aromatic, and more urinous odor, it is called *Cabardine musk.* The small and inferior *Bucharian* and *Assam musk-sacs* rarely, if ever, reach this country. The substitution of artificial musk-bags, made from a piece of the hide stitched to a membrane, is readily recognized by the absence of the circular arrangement of the hairs and of the central aperture. Genuine sacs are sometimes slit open, the musk partly removed, and other substances introduced in place thereof. This may usually be detected by being stitched together on the edge of the hide and inside membrane. There is no means of detecting the fraudulent introduction through the orifice of pieces of lead, etc., until after the bags have been opened.

Tests.—Musk should not have an ammoniacal odor, and not contain more than 15 per cent. of moisture. Water dissolves from 50 to 75 per cent. of the weight of the musk; the solution should be deep brown, faintly acid, and scarcely affected by solution of corrosive sublimate (ammonium carbonate). Weak alcohol yields a similar solution. Strong alcohol dissolves about 10 per cent., yielding a slightly colored tincture, which should scarcely become turbid on the addition of water (absence of resins, etc.). Carefully freed from fragments of skin and hairs and heated upon platinum-foil, musk should give off a slightly urinous odor, but very distinct from the odor of burning blood, and should leave about 6 to 8 per cent. of a gray (not red) ash. The German Pharmacopœia has adopted the examination of musk by the method suggested by Bernatzik: a small quantity of musk, kept in a thin layer under oil of turpentine (or warmed with a little glycerin), and examined under the microscope, is seen to consist of diaphanous brown amorphous splinters and lumps, without being mixed with other foreign substances.

Constituents.—Musk, treated with potassa, gives off ammonia; it contains cholesterin, various fatty and waxy substances, gelatinous and albuminous compounds, and salts. The odorous principle volatilizes partly with the vapors of water, but is not a volatile oil; it is most probably formed in the presence of moisture by the slow and continuous decomposition of one of the constituents.

Pharmaceutical Preparation.—Tincture of Musk, U. S. P.

Action and Uses.—Musk is employed in medicine as a nervous sedative and for the purpose of acting as a diffusible stimulant in conditions of profound feebleness or asthenia, as in the advanced stages of typhoid fever. The dose for these purposes is 20 grains (1.3 Gm.) given in starch water by the rectum. By the mouth it is given in the dose of from 2 to 5 grains (0.12–0.30 Gc.) in pill, or in the dose of from ½ to 1 drachm (2–4 Gm.) of the tincture, for obstinate hiccough and for gastro-intestinal flatulence. At one time it was a very popular remedy, but it is now rarely employed.

Artificial Musk.—Under the names of *tonquinol* and *Bauer musk,* trinitro-butyl-toluene has been introduced as artificial musk, chiefly for use in perfumery. It is made by action of tertiary butyl chloride on toluene in the presence of aluminum chloride, the resulting compound being slowly added to 5 times its weight of a mixture of 2 parts of fuming sulphuric acid and 1 part of nitric acid of 1.5 specific gravity, and the whole heated on a water-bath for 8 or 10 hours. Upon pouring the mixture finally into water, trinitro-butyl-toluene, $C_6H.CH_3.C_4H_9.(NO_2)_3$, is precipitated and may be recrystallized from alcohol. It occurs in the form of colorless or slightly yellowish needles, which melt at 96.5° C. (205.7° F.) and possess a strong, musk-like odor.

Allied Drugs.—Antilope Dorcas L.—This is a deer-like ruminant inhabiting northern Africa. Its small globular excrements have a strong musk-like odor, and have been recommended as a substitute for musk, more especially in perfumery. Jacqueme obtained from them 7 per cent. of alcoholic extract, consisting of biliary substances, of a crystallizable acid, and of an odorous resin, which is also soluble in carbon disulphide. Water dissolves ammonium and sodium salts, and the insoluble portion contains calcium phosphate.

Hyraceum is supposed to be the dry excrements of the *klipdas* or *badger* (*Hyrax Capensis* Cuvier), a mammal of the order *Hyracoidea,* inhabiting southern Africa and attaining a

length of about 45 Cm. (18 In.). Hyraceum is in irregular tough but plastic pieces of a black-brown color; when warmed of a castor-like odor and having a bitter, nauseous taste. It is partly soluble in water, less soluble in alcohol and ether, and when heated becomes soft, and afterward burns, giving off acrid vapors. It contains a volatile oily matter, resin, fat, various acids, biliary constituents, etc.

CIVETTA, ZIBETHUM.—*Civet*, E.; *Civette*, Fr. Cod.; *Zibeth*, G.; *Zibeto*, Sp.—This is an unctuous secretion contained in a pouch located between the anus and genitals of both the males and females of *Viverra Civetta* Schreber, and *V. Zibetha* Schreber (Class *Mammalia*, Ord. *Carnivora*). The former animal inhabits Africa, the latter southern Asia, and they are occasionally kept captive for collecting the secretion, which is removed by means of a small ladle. It is at first yellowish, but becomes dark-brown, is fusible, nearly insoluble in water, partly soluble in ether and in hot alcohol, and has a strong musk-like odor and a bitterish, acrid, nauseous taste. It contains volatile oil, different fats, resin, coloring-matters, and salts.

The above substances are sometimes, though rarely, employed as stimulants and antispasmodics, but are more or less used in perfumery.

MUCILAGINES.—Mucilages.

Mucilages, Fr.; *Schleime*, G.

These preparations consist of viscid, more or less tenacious, and adhesive liquids, or of opaque semiliquid jellies; in all cases the solvent vehicle is water. All mucilages as directed by the pharmacopœias are prone to change, and gradually acquire an acid reaction and offensive odor, at the same time becoming more liquid. If not intended for medicinal use, the change may be retarded or prevented by the addition of alum, creosote, or glycerin.

MUCILAGO ACACIÆ, *U. S.*, *Br.*—Mucilage of Acacia.

Mucilago Gummi Arabici, P. G.—*Mucilage of gum arabic*, E.; *Mucilage de gomme arabique*, *Mucilage arabique*, Fr.; *Gummischleim*, G.

Preparation.—Acacia, in small fragments, 340 Gm.; lime water, 330 Gm.; water, a sufficient quantity to make 1000 Gm. Wash the acacia with cold water, and let it drain; then add to it the lime water and sufficient water to make the mixture weigh 1000 Gm.; agitate or stir occasionally until it is dissolved and strain.—U. S.

To prepare 1 pint of mucilage of acacia use 6 avoirdupois ounces and 175 grains of selected acacia, 5 fluidounces of lime water, and 7 fluidounces of water; after solution has been effected add sufficient water to make the required volume.

Gum arabic, 4 ounces (avoirdupois); distilled water, 6 fluidounces (Imperial).—Br. Gum arabic, 1 part; distilled water, 2 parts.—P. G. Powdered gum arabic, 1 part; cold water, 1 part; dissolve in a mortar.—Fr. Cod.

Owing to the fact that the solution of acacia becomes denser as it progresses, stirring or agitation of the mixture will be found somewhat difficult, and solution can be more readily effected by what is known as circulatory displacement, namely, the suspension of the washed acacia in the water in a bag of loosely textured cloth; if the bag be occasionally moved about in the liquid, fresh portions of water will continually displace the solution formed, which latter will sink to the bottom by reason of its gravity. The addition of lime water is made for the purpose of neutralizing the natural acidity of the acacia solution caused by the presence of acid calcium arabate. Mucilage of acacia should be kept in well-stoppered, completely filled bottles in a cool place.

White and clear pieces of gum arabic should be selected for preparing this mucilage. The impurities which necessitate the subsequent straining are generally accidental admixtures of the gum, and may mostly be removed by rapid washing with cold water before dissolving it.

Mucilage of acacia is a nearly transparent, colorless, or scarcely yellowish, viscid liquid, having a faint rather agreeable odor and an insipid taste. It forms turbid mixtures with solutions of alkali carbonates and bicarbonates, due to precipitation of calcium carbonate.

Pharmaceutical Uses.—This mucilage serves for the suspension of insoluble substances in mixtures and to impart adhesiveness to pill masses. The British Pharmacopœia directs it to be used as an excipient in the preparation of troches.

MISTURA GUMMOSA.—*Potio Gummosa.*—*Gum mixture*, E.; *Potion gommeuse*, *Julep gommeux*, Fr.; *Gummimixtur*, G.—Powdered gum, 10 parts; syrup, 30 parts; water, 100 parts; and orange-flower water, 10 parts.—Fr. Cod.

Uses.—Mucilage of acacia is employed as a soothing agent in inflammatory conditions of the respiratory, digestive, and urinary tracts. It may be diluted and flavored to suit the taste. The ordinary dose is from 1 to 4 fluidrachms (4–16 Cc.).

MUCILAGO SALEP, *P. G.*—Mucilage of Salep.

Mucilage de salep, Fr.; *Salepschleim*, G.

Preparation.—Salep, in fine powder, 1 Gm.; cold water, 9 Cc.; boiling water, 90 Cc. Place the powdered salep in a flask containing the cold water, and shake until the powder is uniformly distributed. Then add the boiling water, and shake the mixture continuously until it has become cold. The cooling may be hastened by frequent and brief immersion of the flask in cold water. Mucilage of salep should be freshly made when wanted for use.—P. G.

If sugar or syrup is prescribed in the same mixture with mucilage of salep, it is preferable to triturate the required quantity of powdered salep with either of the former, as the case may be, and then to add rapidly the proportionate amount of boiling water.

Uses.—This preparation may be given as a demulcent.

MUCILAGO SASSAFRAS MEDULLÆ, *U. S.*—Mucilage of Sassafras Pith.

Mucilage de moëlle de sassafras, Fr.; *Sassafrasmarkschleim*, G.

Preparation.—Take of sassafras pith 2 Gm.; water, 100 Cc. Macerate for 3 hours, and strain. It should be freshly made when wanted.—U. S.

It is a colorless, thickish, transparent liquid of a bland taste.

Uses.—Mucilage of sassafras pith may be given in bronchial affections and intestinal disturbances. It has been recommended as a local application for acute conjunctivitis.

MUCILAGO TRAGACANTHÆ, *U. S., Br.*—Mucilage of Tragacanth.

Mucilage de gomme adragante, Mucilage adragant, Fr.; *Traganthschleim*, G.

Preparation.—Tragacanth, 6 Gm.; glycerin, 18 Gm.; water, a sufficient quantity to make 100 Gm. Mix the glycerin with 75 Cc. of water; heat the mixture to boiling, add the tragacanth, and let it macerate for 24 hours, stirring occasionally. Then add sufficient water to make the mixture weigh 100 Gm., beat it so as to render it of uniform consistence, and strain forcibly through muslin.—U. S.

The Br. P. directs that 60 grains of powdered tragacanth be mixed with 2 fluidrachms of 90 per cent. alcohol, after which sufficient distilled water is added to form 10 fluidounces, and the whole well shaken.

Uses.—This mucilage may be employed locally as a protective to burns and scalds.

MUCILAGO ULMI, *U. S.*—Mucilage of Elm.

Mucilage d'écorce d'orme fauve, Fr.; *Ulmenrindenschleim*, G.

Preparation.—Elm, bruised, 6 Gm.; water, 100 Cc. Digest for 1 hour in a covered vessel on a water-bath, and strain.—U. S.

The mucilage contains at least a portion of the starch of the bark; if intended to be free from starch, cold water should be used.

Uses.—Elm mucilage is employed for its demulcent properties in the treatment of inflammatory affections of the respiratory, intestinal, and urinary tracts. It may be applied locally for the relief of erysipelas and other cutaneous inflammations.

MUSCI.—The Mosses.

This very large group of plants is probably of less economic importance, except for some mechanical uses, than any other of similar size. Its medicinal products are almost limited to a few species used for their mildly expectorant, and in some cases diuretic properties. *Hypnum cupressiforme* L. is credited with slight antiperiodic properties. *Funaria hygrometrica* Hedw. and *Meesia uliginosa* Hedw. are used as diuretics.

Polytrichum (*Hair-cap, Ground, Bear, Besom*, or *Golden moss, Robin's rye, Bear's bed,*

Goldilocks, Silver ling or *heather, Golden maiden-hair,* E. ; *Goldner Widerthon,* G.) is the entire plant of various species of *Polytrichum,* especially *P. commune* L. and *P. juniperinum* Hedw., of Europe and the United States, used commonly under the name *Herba adianthi aureæ.* The last-named plant grows in dense beds, on somewhat shaded banks. The stems are mostly simple, a few inches high, polished, and of a reddish color ; leaves spreading or appressed, lance-linear, awned, entire, but the edges somewhat incurved ; capsule quadrilaterally ovoid-oblong, the edges acute. The constituents are unknown. It appears to have quite active diuretic properties.

MYRICACEÆ.—The Bayberry Family.

This family, of 1 or 2 genera and less than 50 species, is of medicinal interest because of the generally aromatic properties of its foliage, the astringency of many of its barks, and the wax yielded by the fruits of many species. The last-mentioned product has been considered under CERA.

MYRICA (*Wax-myrtle, Bayberry, Tallow bayberry, Candle-berry, Wax-berry, Tallow shrub,* E. ; *Wachsmyrtel, Wachsbaum, Wachsgagel,* G.; *Arbre à suif,* Fr.; *Arbol de la Cera,* Sp.) is *Myrica cerifera* L., a densely growing evergreen shrub of about the height of a man, or less, abundant, mostly in the coast-region of the eastern and southern United States. The flowers appear in early spring, the staminate in yellow cylindraceous catkins about 18 Mm. ($\frac{3}{4}$ In.) long, the pistillate in smaller greenish aments. The fruits are globular, 1-seeded nuts, blackish, but densely covered with a bluish-white wax. *The leaves* are here illustrated. They are thick and smooth, except for the resinous dots on both sides, and are highly aromatic, like *Myrcia leaves,* when bruised, and of a somewhat bitter and astringent taste. Their important constituent is about 0.021 per cent. (*Gildemeister and Hoffmann*) of a greenish volatile oil, of a specific gravity of 0.926 and congealing in a freezing mixture. The leaves have some celebrity in domestic practice as an antispasmodic, antiscorbutic, and astringent, and have been used in hæmoptysis. *The bark* occurs in quills or curved pieces about 1.5 Mm. ($\frac{1}{16}$ In.) thick, externally covered with a whitish, slightly wrinkled, thin, corky layer, which separates in small fragments, underneath which the bark is dark reddish-brown and nearly smooth, resembling the inner surface, except that the latter is slightly striate. The fracture is granular, of a pale-reddish color, and scarcely fibrous in the inner layer. The bark yields a light reddish-brown irritating powder, which has a peculiar aromatic odor and an astringent somewhat bitter and pungently acrid taste. The constituents of bayberry bark, as determined by G. M. Hambright (1863), are, besides those more generally met with, a trace of volatile oil, tannin, an acrid resin soluble in alcohol and ether, an astringent resin insoluble in ether, and *myricinic acid,* the latter obtained from the alcoholic extract, after having been treated with ether, by exhausting it with hot absolute alcohol. It forms small granules, which produce a thick froth on being agitated with water, and on the addition of ammonia a deep-green color, rapidly changing to red and yellow. It has a lastingly acrid taste. Dana obtained from the fruit 32 per cent. of solid fat, 5 of resin, and 45 of starch. The myrtle-wax consists, according to G. E. Moore, of about one-fifth palmitin, the remainder being palmitic acid, with a small quantity of lauric acid. The bark of the root is acrid and stimulant, and in doses of a drachm causes a sensation of heat in the stomach, followed by vomiting and sometimes by diuresis. When chewed, it acts as a sialagogue, and has proved useful in *toothache.* The powder is an active errhine. Myrica has been employed internally for its tonic and astringent properties. In large doses it is said to be diuretic and emetic. Externally, the leaves are said to possess antiscorbutic and astringent properties. A decoction of 1 ounce (30 Gm.) to 1 pint (480 Cc.) may be given internally in doses of 2 fluid-ounces (60 Cc.) in the treatment of dysentery and scrofulous affections. The dose of the powdered drug is from 10 to 30 grains (0.60–2 Cc.). An alcoholic extract may be given in 5-grain (0.30 Gm.) doses.

FIG. 278.

Myrica cerifera (Nat.).

M. Gale L. (*Gale Belgica* Hum.), the *Sweet gale, Dutch myrtle,* E. ; *Piment royal, Galé odorant,* Fr.; *Gagel, Brabanter Myrte,* G., is a smaller shrub than the preceding, growing in swampy places from the mountains of North Carolina northward to Canada, and in the

northern parts of Europe and Asia. The leaves are on short petioles, obovate-lanceolate, wedge-shaped at the base, serrate near the apex, subcoriaceous, softly pubescent beneath, and bears on both sides yellow resinous dots. The fruit is likewise resinous-dotted. The leaves and brown branches have a strong balsamic odor and an aromatic, astringent, and bitterish taste. Rabenhorst (1836) obtained from 3000 parts of leaves 1 part of a thickish volatile oil containing 70 per cent. of stearopten.

The genus comprises about 35 species and most of them share the above composition and properties. *M. Nagi* Thunb., of India, is especially employed, the bark largely used as a tanning agent, and also for dyeing. It contains the coloring-matter *myricetin* ($C_{15}H_{10}O_8.H_2O$) and the quercitrin-like glucoside *myricetrin* ($C_{21}H_{22}O_{13}.H_2O$), which yields the former and rhamnose. When deprived of its water, it occurs in pale-yellow laminæ.

COMPTONIA (*Sweet fern, Ferngale, Meadow fern, Fern bush, Bush* or *Shrubby fern, Sweet bush, Spleenwort bush*, E.; *Liquidambar à feuilles de caterach*, Fr.) is the leaves of *Comptonia*

FIG. 279.

Comptonia leaf (⅔ Nat.).

peregrina (L.) Coulter (*Liquidambar p.*—L.; *Myrica asplenifolia* Gærtn.; *M. Comptonia* DC.), a low shrub, abundant in dry meadows, especially on rocky hillsides and among blueberry bushes, in northeastern North America. The leaf is here illustrated. It is deciduous, thin, pubescent and resinous-dotted, and has an aromatic odor and taste, much like *Myrica*, and is slightly astringent. The dried leaves yield a saponin-like substance, resin, 0.08 per cent. of aromatic volatile oil, gallic acid (?), fat, and 7–10.5 per cent. of tannin, the greater amount in summer. The dried rhizome yielded 6 per cent. of tannin and 8.24 per cent. of starch. The oil has a cinnamon-like odor and a specific gravity of 0.926. Sweet fern is stimulant and astringent; sometimes used to relieve colic and check diarrhœa and as a fomentation in rheumatism.

MYRISTICA, *U. S., Br.*—Myristica; Nutmeg.

Semen myristicæ, P. G.; *Nux moschata, Muscade, Noix muscade*, Fr. Cod.; *Muskatnuss*, G.; *Noca moscata*, It.; *Nuez mosedda*, Sp.; *Noz moschada*, Port.

The kernel of the ripe seed of *Myristica fragrans* Houttuyn (*M. officialis* L. f.; *M. moschata* Thunb.; *M. aromatica* Swz.; *Palala fragrans* Kuntze.—Fam. *Myristicaceæ*).

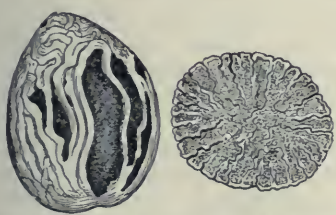
Nutmeg is official in all pharmacopœias.

Origin.—From a handsome, small, evergreen, dicœcious tree, native of the Molucca Islands, but the product now obtained wholly from trees cultivated in various tropical countries. It bears a dense crown of dark-green, somewhat lustrous foliage, inconspicuous yellowish flowers and a fleshy fruit much resembling a peach. The pericarp splits into halves at maturity, disclosing the solitary seed, partly covered by the scarlet aril (see illustration). This aril, removed and dried, constitutes MACIS. The seeds are then dried at a carefully maintained temperature of about 140° F., being in some cases (as at Bencoolen) first exposed for some hours to sunshine. The drying process requires many weeks. The testa then exhibits a rich brown color, somewhat shining and slightly furrowed where the mace has laid upon

FIG. 282.

Wild nutmeg, with mace.

FIG. 280.



Nutmeg with mace, and transverse section.

FIG. 281.

Nutmeg with testa (Nat.).

it. The kernel has shrunken so that it rattles loosely within the testa. In this condition, the seed constitutes the "Chinese Nutmeg," so called because it is the form imported by the Chinese. For use by other peoples the testa is broken and the kernel shelled out and exported, either in its natural condition (*Brown* or *Penang Nutmeg*, as the U. S. P. definition would require), or after having received a coating of lime (*Limed* or *Dutch Nutmegs*). It has been said that the liming process was originally resorted to by the Dutch to kill the vitality of the kernel, thus preventing the possibility of the loss of their monopoly, but since it affords an important protection against the attacks of insects, to which nutmegs are very liable, this may have been the real object of the procedure.

Although nutmegs are grown for local consumption in many tropical countries, the only considerable export is from the Malay Archipelago. The term "Banda," applied to Nutmegs and Mace, is a relic of the period of original export from the Banda Islands. Good crops of excellent, though rather small nutmegs are produced in the West Indies, but the industry is local and small.

Description.—Nearly 2.5 Cm. (1 In.) in length and of varying breadth, but never narrow and pointed, oval-ovoid, marked at the broad end with a circular scar, from which proceeds a shallow furrow to a deeper depression near the smaller end, and by a coarse reticulation of shallow furrows over the entire surface. In the official article the color is a light-brown, with a slight waxy luster, but the ordinary nutmeg of commerce is more or less grayish-white from a partial coating of lime. The embryo is small and occupies a conical cavity near the broad end, the remainder of the nutmeg consisting of endosperm. The transverse section exhibits a pale brownish-yellow, fatty-lustrous surface, penetrated by numerous narrow curved channels filled with brown tissue and containing involutions of the tegmen. Nutmeg is strongly and pleasantly aromatic in odor and taste, the latter also somewhat bitter and slightly pungent. Pure nutmeg yields not more than 2.5 per cent. of ash, though 5 per cent. is commonly allowed.

Substitutes and Adulterants.—No other natural product sufficiently resembles nutmeg to substitute it successfully in the natural condition, though a number of the kernels described under *Other Species* are occasionally reported. The most important of these is called *Long*, *Wild*, or *Male Nutmeg*, an important article of commerce for its fat, which is used to substitute or adulterate Nutmeg Butter. This nutmeg is commonly referred to *M. fatua* Houtt. (*M. tomentosa* Thunb.), but Warburg states that there are two varieties of it, the species yielding the better one being called by him *M. argentea*. Both varieties are much longer, narrower, and more pointed than the official. That from *M. argentea* he describes as differing from the other in being more brittle and with a stronger aroma, more resembling that of the official nutmeg, and in being furrowed with four broad stripes united above and below. That from *M. fatua* possesses almost no aroma after being dried. *Artificial Nutmegs* have been reported from time to time. Those examined by Vanderplankin closely resembled the natural externally, but were so softened by heating for 3 minutes in boiling water that they fell to pieces when rubbed between the thumb and finger. They were formed by compression of some mixture of earthy and powdery matter. Although aromatic, the aroma is weaker and somewhat different from that of the genuine. They yield from 11 to 18 per cent. of ash, only about 15 per cent. of fat, and less than 2 per cent. of volatile oil. The so-called *California Nutmeg*, the seeds of *Torreya Californica* Torrey (*T. Myristica* Hooker.—Fam. *Pinaceæ*), was formerly offered. These are readily distinguished by their smooth surface and their terebinthinate odor and taste. Ground nutmeg is heavily adulterated, especially with refuse nutmegs which have been distilled. Doubtless more or less of the kernels of *M. Malabarica* Lam., from which the Bombay Mace (see adulterants of Macis) has been removed, are also thus utilized. Since the practice of purchasing for consumption nutmegs in the entire state is almost universal, the adulterants of the ground article are of slight interest.

Constituents.—Nutmeg is commonly stated to contain from 2 to 8 per cent. of volatile oil (see Oleum Myristicæ), but it is a poor article which does not yield to the distiller at least double the larger amount named. Pressure removes 25 to 30 per cent. of fixed oil (*Oleum Myristicæ Expressum* or *Nutmeg Butter; Oleum Nucistæ*, P. G.), which commonly carries considerable of the volatile oil in solution, and about a third as much more remains in the pummice, Proteids, gum, and a peculiar starch are also present.

Action and Uses.—Nutmeg possesses aromatic, narcotic, and intoxicating properties. Given in overdose it produces stupor, decreased reflex excitability, slowness of

respiration, and slight cardiac sedation. It is not largely employed in internal medicine, but it may be combined with purgative drugs for its corrigent effect. It is largely employed as a condiment, and is especially useful as such in cases of gastric debility. The expressed oil is occasionally employed externally as a mild counter-irritant. The internal dose of the powdered drug is from 5 to 10 grains (0.30–0.60 Gm.).

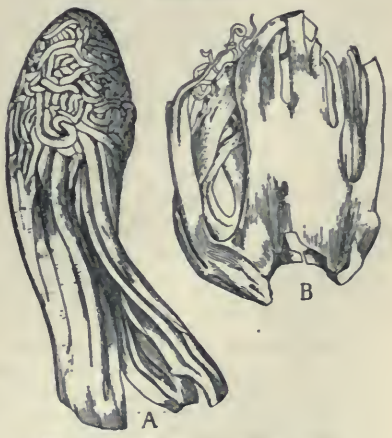
The properties and dose of mace are practically the same as those of nutmeg.

Other Species.—The genus *Myristica* L. contains about 80 species. The kernels of many are but faintly, some not at all, aromatic, while several (*M. succedanea* Scheinw., *M. argentea* Warb., *M. speciosa* Warb., *M. Schefferi* and *M. Madagascariensis* Lam.) are said to compare favorably with the official. Quite a number of the inferior ones, though not employed like nutmeg, have native medicinal uses. *M. fatua* is an important antidysenteric in the Moluccas. *M. Surinamensis* Bl., the "Cuago" or "Ucuhuba," yielding *Ucuhuba* or *Ocuhuba fat*, *M. Bicahyba* Schott., the "Bicahyba," and *M. officinalis* Mart., the "Bikuiba," all of tropical America, have important uses as antispasmodics and intestinal stimulants. *M. sebifera* (Aubl.) Sw. (*Virola s.* Aubl.) yields a red juice somewhat similar to Kino, which is used as an astringent; also a wax (*Ocuba wax* or *Virola tallow*). In the Philippines, the seed of *M. Philippinensis* Lam. (*M. Lusonensis* Man.) is used as a nutmeg-substitute, under the names *Dragon*, *Dunghan*, and *Gono-gono*. *M. gibbosa* Hook. f. et T., and *M. kingis* Hook. f., Indian species, yield a kind of Kino. So-called *Jamaica*, *Mexican*, or *Calabash nutmegs* are from *Monodora Myristica* (Gærtn.) Dunal (*Anona M.* Gærtn.—Fam. *Anonaceæ*). *Clove nutmegs* are from *Agathophyllum aromaticum* Willd. (*Ravensara a.* J. F. Gmel.—Fam. *Lauraceæ*).

Macis (*Arillus Myristicæ.—Mace*, *Banda Mace*, E.; *Muskatbluethe*, G.; *Fleur de Muscade*, Fr.; *Machias*, Sp.; *Arillo do Noz Moschada*, Port.) is the arillode removed from the Nutmeg seed, as described under that title. It is commonly dried in the sun and is often sprinkled with sea water, this being supposed to aid in its preservation.

Description.—Flat; nearly 2.5 Cm. (1 In.) long or sometimes longer, and of variable width, about 2 Mm. ($\frac{1}{12}$ In.) thick at the base, becoming gradually thinner upward, irregularly palmately divided into narrow, somewhat branching bands; smooth, very slightly lustrous, brownish-orange, slightly translucent, exuding oil when pressed or scratched; fracture short and weak; of a pleasant nutmeg-like aroma and taste.

FIG. 283.



Mace: A, Bombay; B, official (Nat.).

Adulterants.—Powdered Mace is heavily adulterated with Wild, Bombay, or Malabar Mace, derived from the seed of *Myristica Malabarica* Lam., and perhaps also from *M. fatua* Houttuyn. Whether in the entire or powdered condition, this adulterant is readily detected. In the entire condition, it is longer and relatively narrower, less divided at the base, the divisions more slender, the color darker and more reddish or brown, the surface more lustrous, the odor and taste weaker, more fatty, and having more of a resinous character. The addition of so little as 1 per cent. to genuine powdered mace can be easily detected by the treatment of a microscopic specimen with potassium hydroxide solution, which turns the particles of a dark-brown color, which becomes yellow upon the addition of sulphuric acid. The spurious article yields 10 times as much ether-extract as the genuine, after removal of the fat by petroleum ether, that from genuine mace not exceeding 5.5 per cent. If there be an addition of only 10 per cent. of the spurious article, the ether-extract is thus brought up to 6 per cent. (*Solstein*).

Constituents.—The important constituents are the fixed and volatile oils. The latter exists to the extent of from 4 to 9 per cent. or more, occasionally up to 17 per cent. There are two odorous fixed oils, one yellow and soluble in ether, insoluble in boiling alcohol, the other red and miscible in all proportions with alcohol and ether. There are also 25 per cent. of soft resin, 1.8 per cent. of amylodextrin, 1 per cent. of uncrystallizable sugar, a little myristicin, gum, etc. Starch is wanting. The ash should not exceed 3 per cent.

Action and Uses.—The action of mace is practically the same as that of MYRISTICA (which see). It is occasionally employed to impart an agreeable taste to medicines, and is added as a condiment to certain articles of diet.

MYRRHA, *U. S., Br., P. G.*—Myrrh.

Somali Myrrh, Herabol Myrrh, Gummi resina Myrrha.—Resina Balsamodendri, Nor.; *Myrrhe,* Fr. Cod., G.; *Mirra,* Sp., Port., It.

A gum-resin obtained from *Commiphora Myrrha* (Nees) Engler (*Balsamodendron M.* Nees; *Balsamea M.* Baill.—Fam. *Burseraceæ*).

Myrrh is official in all pharmacopœias. The Br. P. definition employs the synonym *Balsamodendron M.*, and adds "probably from other species." The P. G. uses the proper generic name, *Commiphora,* but gives the species as *C. Abyssinica* (Berg.) Engl. and *C. Schimperi* Engl. Other pharmacopœias have incorrectly defined the plant as *B. Opobalsamum* Kunth. (*B. Ehrenbergianum* Berg.).

Origin.—The determination by Nees of *C. Myrrha* as the source of Myrrh has been at various times called into question, but has recently been definitely settled by Holmes, who identified a leaf-bearing specimen collected by Phillips, natural Myrrh being attached to the twigs. There appears to have been some confusion in Engler's transferral of the name from the genus *Balsamodendron* to *Commiphora,* he calling the Myrrh plant a variety of the species *C. Myrrha,* but it is quite clear that the specific name *Myrrha* can never belong to any other than the species to which it was originally applied by Nees. Holmes's shrewd observations, based upon an examination of the same specimens which gave origin to the idea that the substance is derived from *C. Abyssinica* and *C. Schimperi,* as well as of other specimens, have sufficed, furthermore, to render it exceedingly unlikely that any other species than that named in our definition yields Myrrh corresponding to the official description. Even if the inferior Arabian Myrrh were to be officially accepted, its reference to *C. Schimperi* would not appear justified. The occurrence of Myrrh in the bark, in both lysigenous and schizogenous ducts, renders it an easy matter for an expert pharmacogonist to determine its origin, by an examination of good herbarium specimens.

Official Myrrh is collected by the Somalis in northeastern Africa, partly from natural fissures and partly from incisions made for the purpose. It is at first yellowish-white, but as it hardens becomes darker, until finally of a reddish-brown color and without the rough and powdery surface characteristic of the commercial article. It is accumulated at Aden and Berbera, chiefly the former. Long ago, it went from there to India and Turkey, whence it was re-exported. That passing through Turkey was of the best grades only, hence the titles, now obsolete, of "Turkish" and "Indian" Myrrh. Up to recent times, most of our Myrrh was imported from India, but it now chiefly comes direct from Aden. It is assorted before being exported, but more or less spurious and inferior pieces are commonly found intermixed.

Description.—In irregular, more or less rounded nodules or tears, from 2.5 to 10 Cm. (1 to 4 In.) in diameter, the surface more or less roughened by nodules and small cavities, as though eroded, red-brown, dull, and more or less gray from adhering powder; heavy, hard, and rather tough-splintery in fracture, the freshly-fractured surface of a waxy luster and oily feel, red-brown, usually variegated by gray crescent-shaped spots and intersecting lines; thin fragments translucent, usually strongly so; strongly and agreeably aromatic, the odor characteristic; bitter, and somewhat acrid, and producing a hardening and slight wrinkling of the mucous membrane of the mouth, though different from the astringency of tannin; readily powdered when cold and dry, but with difficulty when warm and damp; the freshly fractured surface, moistened with alcohol, colored purplish, as is the brownish-yellow alcoholic tincture, by nitric acid (distinction from Bdellium); yielding a brownish-yellow emulsion with water; the 10 per cent. ethereal extract acquiring a violet color in the presence of bromine vapor, or the film left from the evaporation of such an extract in a watch-glass slowly acquires such a color if inverted over another watch-glass containing nitric acid; if 6 drops of a 7 per cent. petroleum-ether extract be mixed with 3 Cc. of acetic acid, and 3 Cc. of sulphuric acid be then added, forming a heavy lower layer, the latter takes only a light-rose color, which does not deepen (*distinction from Bissabul Myrrh*); not more than 70 per cent. should be insoluble in alcohol, and the ash should not exceed 6 per cent.

In connection with the above description, the following facts should be considered: the tears of genuine Myrrh are of all sizes under 1 inch, but these smaller forms are

inferior and more likely to be spurious; on the other hand, very large masses sometimes occur, but one of the varieties of Bdellium usually occurs in such masses. The ash-limit is sometimes placed at 10 per cent., but in a first-class article it is not more than 2 or 3 per cent., and the limit given above is a liberal one. Different pharmacopœias variously state the alcohol-insoluble portion at from 60 to 66 per cent., the Italian saying "from 40 to 60 per cent." The smaller the amount, the better the Myrrh, and a strictly good article should yield not more than 65 per cent.

Merson (*Pharm. Jour. and Trans.*, Jan., 1900, p. 42) has made an extensive comparison of commercial samples, showing that the poorest ("small, common sorts") contain 33 per cent. soluble in 90 per cent. alcohol, and nearly 14 per cent. of ash. From this, the quality gradually improved through 11 successive grades up to a "select medium"-sized article which yielded about 48 per cent. to 90 per cent. alcohol and less than 3 per cent. of ash.

Other Varieties, Substitutes, and Adulterants.—While the official tests given under *Description* suffice for the distinction of Myrrh from all common admixtures and substitutes, yet the very best method of distinction, for one familiar with the article is by the odor and taste.

Arabian Myrrh rather closely resembles the official, but its largest fragments rarely much exceed half the size of large fragments of the latter. It contains more gum, commonly above 70 per cent., and less volatile oil. Its surface is less dusty, it is tougher, the fragments less transparent, the fractured surface rarely (never in the variety which commonly occurs) spotted or veined, and the odor is less fragrant. It is represented by two principal varieties, the Fadhli and the Yemen. The latter, scarce in commerce, is the poorer, being dark-colored, very gummy, and of a peculiar heavy, not agreeable odor. It does not react to the bromine test.

Bissabul, or *Bisabol Myrrh* or *Hebbakhade*, referred by Holmes to *C. Kataf* (Kunth) Engl., is much like the genuine in color, though lighter and more yellowish, but not so dusty. It is characteristically soft and gummy, and the fractured surface exhibits small brown, angular resin-spots. Its odor is not disagreeable, but is sufficiently distinct from that of Myrrh. The filtrate from its 50 per cent. extract with cold petroleum ether is yellow, while that from genuine myrrh is colorless. On applying the acetic-sulphuric acid test described above, the lower layer becomes rose-red, changing shortly to deep-red. Bissabul Myrrh contains only about 21 per cent. of resin, which is strongly acid, 1.5 per cent. of bitter constituent, and up to 8 per cent. of volatile oil. To the latter, which has been called *Bisabolene*, is attributed the color-reaction last mentioned. It is light-yellow and of a specific gravity of 0.8836 (Gildemeister and Hoffmann). Bissabul Myrrh is said to be now in commerce under the name of *Opopanax*.

Bdellium.—This substance probably constitutes the commonest and most important adulterant of Myrrh. It presents several quite distinct varieties. *African Bdellium*, from *C. Africanum* (Arn.) Endl. (*Balsamodendron A.*—Arn.; *Hendeletia A.*—Rich.; *Balsamea A.*—Baill.), is powdery on the surface, hard, rather brittle, the fractured surface dark red-brown, not or little lustrous, the thin fragments slightly translucent and deep-red. It is aromatic, but the odor is quite distinct from that of Myrrh, and it is quite bitter. *Indian Bdellium*, probably from *C. Mukul* (Hook) Engl., is similar in appearance, but is slightly or not at all aromatic and not bitter. The fractured surface is peculiarly sparkling from the presence of small resin-dots and the fragments are somewhat translucent. Another variety is sometimes seen which is intermediate between these two in odor and taste, but not at all translucent, and very distinct from the others in having its tincture blackened by ferric salts.

Constituents.—Myrrh ordinarily contains from 2 to 5 per cent. of volatile oil. The amount is occasionally considerably higher, but a high percentage occurs regularly in Bissabul Myrrh, the oil, however, being of a very different character. There is 25 to 40 per cent., occasionally in select pieces nearly 50 per cent. of resin, the remainder mostly gum. The bitter principle is sparingly soluble in water, partly in carbon disulphide, soluble in ether and alcohol, and precipitated from alcohol by lead acetate. Its alkaline solution reduces Fehling's Solution and precipitates floccules on the addition of acid. *Oil of Myrrh* (Myrrhol), which is an article of commerce, is a yellow or yellowish-brown thickish liquid having the intensified odor of myrrh, its specific gravity varying from 0.988 to 1.007 (*Gildemeister and Hoffmann*). Its boiling-point is most variously stated by different authors. Dissolved in carbon disulphide, it gradually

assumes a permanent violet or blue color after the addition of nitric acid or bromine. Its constituents are entirely unknown.

Resin of Myrrh has been much studied, but is not yet well known. It is entirely soluble in ether, alcohol, and chloroform. It consists of 2 parts, one soft, the other hard and acid, the latter being again divisible into 2 parts. This acid portion yields protocatechuic acid and pyrocatechin.

Myrrh Gum consists of 2 parts, one soluble, the other swelling in water. The relative proportions of the two parts appear quite variable. This gum is considered of good quality for mucilage, its keeping qualities being unusually good.

Pharmaceutical Preparations.—Compound Iron Mixture, Pills of Aloes and Myrrh, Tincture of Aloes and Myrrh, Tincture of Myrrh, U. S. P.

Action and Uses.—This substance is employed for its tonic and stimulating properties. In moderate doses it acts as a mild circulatory stimulant, and increases the activity of the respiratory, gastric, and uterine mucous membranes. It may be employed as an expectorant in subacute and chronic bronchitis, and is believed to be of value in the treatment of chronic cystitis, and leucorrhœa depending upon chronic metritis. When combined with iron, it is frequently used in the treatment of amenorrhœa depending upon chlorosis or functional inactivity. Locally applied, it is a useful application to spongy gums, aphthous stomatitis, and indolent ulcers. In the treatment of anæmia it may be given in the form of Mistura Ferri Composita (which see). The drug is rarely administered in substance, but an emulsion may be prepared and given in doses representing from 10 to 15 grains (0.60–1 Gm.). The tincture is usually employed as a local application for ulcerative sore throat, but may be given internally in doses of from 10 to 30 minims (0.6–2 Cc.).

Allied Substances.—The genus *Commiphora* is credited by Engler with 63 species, all of Africa and adjacent Asia, and as a class characterized by their gum-resinous exudations. Probably most of the substances occurring as substitutes for and adulterants of Myrrh are derived from this genus. Several are independent articles of commerce.

Mecca Balsam, Balm of Gilead, or *Opobalsamum,* is the product of *C. Opobalsamum* (Kunth) Engl. While this species is said to have a very wide distribution, the Balsam is collected only in the vicinity of Mecca. The substance is of interest because it appears to be that referred to in the Bible under the name of Myrrh. The method of its collection appears to be unknown. It is an opaque, yellowish or whitish, fragrant, viscid liquid, containing from 10 to 30 per cent. of volatile oil, according to different authors, and up to 70 per cent. of soft and 12 per cent. of hard resin. This substance, formerly an important article of commerce, is now rarely seen.

Mulu Kilavary is an exudation from *C. Berryi* (Arn.) Engl. It is described by Hooper as occurring in tough, translucent fragments, ranging from pale-yellow to brown and breaking with a shining conchoidal fracture, the surface oily and, when scratched, showing a milky-white marking. The odor was oily, not fragrant, and the taste simply mucilaginous. It yielded 5 per cent. of moisture, 6.6 per cent. of mineral matter, and 84 per cent. of gum similar to that of Myrrh. The resin was soft, transparent, tasteless, odorless, and neutral, and soluble in alcohol, ether, chloroform, and carbon disulphide. Moistened with alcohol, it gave no color with nitric or hydrochloric acid, and no violet color on treatment with bromine. It appears likely that this is one of the "tasteless gums" which have been reported as used to adulterate Myrrh.

Hotai is a gum-resin obtained from *C. Playfairii* Hook. (now referred to *C. Myrrha*).

Kafal wood is an article of commerce in Egypt, and is said to be yielded by *C. erythræa* Engl.

MYRSINACEÆ.—The Myrsine Family.

A family of about 25 genera and about 500 species of shrubs and trees of tropical and subtropical regions. The properties of its plants have been but little studied, but many of the fruits are purgative and anthelmintic, and the family appears worthy of careful investigation.

Embelia is the fruits of *Embelia Ribes* Burm. (*Samara R.*—B. et H.), a small tree of India. This article has attracted some attention as an adulterant of pepper and cubeb. The drupe is dark-red, drying blackish, and resembles black pepper. It is very aromatic. Warden (1887, 1888) isolated from it *embelic acid,* $C_9H_{14}O_2$, which crystallizes in brilliant golden spangles and is insoluble in water; its alcoholic solution combined with ammonia turns red, and on spontaneous evaporation yields the salt crystalline and tasteless. The fruits are used as an anthelmintic. From 2 to 3 drachms (8 to 12 Gm.) are given with milk before breakfast and followed, after some hours, by a dose of castor oil or other purgative.

Saoria, from Abyssinia, is the fruit of *Mæsa lanceolata* Forsk., *M. pieta* Hochst. It is

drupaceous, globular-ovate, about 4 Mm. (⅛ In.) thick, partly united with the calyx, brownish-green, and contains a resinous pulp with many turbinate angular seeds attached to the central placenta; the taste is bitterish, pungent, and acrid. Apoiger (1857) met with an acrid principle, some iron-greening tannin, volatile oil, fat, pectin, etc. This fruit is also used as a tænicide.

Satzé or Tatzé, the fruit of *Myrsine Africana* Schimp., differs from the preceding in being more globular, not united with the calyx, of a reddish-brown color, and in containing only one nearly globular seed, which is grooved at the base. The taste of the fruit is more disagreeable than that of saoria. It gives a violet tint to the urine and occasions slight nausea and liquid stools. According to some authorities, it is a more certain remedy for *tænia* than the indigenous tænifuges of France, but others regard its action as uncertain. It may be given in powder, mixed with porridge, in the dose of from 1 to 1½ ounces (32–48 Gm.). Strohl found it partly successful in 6 cases of tænia, administering 4 to 6 drachms (16–24 Gm.) of the powder in a liquid vehicle.

The fruit and leaves of *Jacquinia armillaris* Jacq. (*Tuigi da praya* or *Barbaseo*) are poisonous and used in capturing fish.

MYRTACEÆ.—The Myrtle Family.

The Myrtle family comprises 72 recognized genera, according to Niedenzu, and about 3000 species of shrubs and trees, almost wholly of tropical distribution. In its botanical characters, chemical constituents, and physiological and medicinal properties it is very uniform. The plants are highly ornamental, with dense crowns of mostly thick, dark-green leaves, and producing an abundant, usually white inflorescence. The fruits too are often very showy, persisting for some time, and many of them are somewhat edible. The important constituents are volatile oils and tannin, on account of which latter many of the barks are used in tanning. The general character of the volatile oils, which are particularly expectorant and antiseptic, is fully indicated elsewhere, in our accounts of Caryophyllus, Eucalyptus, Oleum Cajuputi, Oleum Myrciæ, and Pimenta. A very large number of the species have been medicinally employed for their similar constituents and properties.

Myrtus or *Myrtle, Common, Dutch, Bridal,* or *Jew's myrtle* (*Myrte,* G., Fr.), is the leaves of *Myrtus communis* L., native of the Mediterranean region, and largely cultivated for decorative purposes. They vary from 1.2 to 5 Cm. (½ to 2 In.) in length, and from lance-linear to ovate in form, and are very short-petioled, mucronate, entire, thick, smooth and glossy, densely pellucid-punctate, finely aromatic, and slightly astringent and bitter. The fruits, which are also used, resemble allspice. The only important constituent is the volatile oil, of which the yield is said to be less than 0.5 per cent. It is yellowish or greenish, has a specific gravity of 0.890 to 0.915. It apparently contains a camphor, with *d*-pinene and dipentene. Myrtle depends for its activity upon the volatile oil which it contains. It possesses some germicidal activity and acts as a nervous sedative. The drug has been recommended in the treatment of chronic bronchitis, pulmonary gangrene, bronchitis, menorrhagia, chronic cystitis, and pyelitis; but it is rarely employed in this country. The powdered drug may be given in from 15 to 30 grain (1–2 Gm.) doses. The dose of the oil is from 2 to 4 minims (0.10–0.25 Cc.), 4 times daily.

Chequen, *Chekan,* or *Arrayan,* used in Chile as a substitute for Myrtle, is the leaves of *Eugenia Chequen* Mol. (*Myrtus Cheken* Spr.; *Eugenia Cheken* DC.). They are nearly sessile, about 1.5 to 2 Cm. (⅗ to ⅘ In.) long, rhomboidally oval, with oblique base, entire and revolute margin, smooth and somewhat shining, pellucid-punctate, highly aromatic, astringent and bitterish. They contain upward of 1 per cent. of a volatile oil very similar to that of myrtle, about 4 per cent. of tannin, and, possibly, a volatile alkaloid and a glucoside. Chekan is said to be a valuable remedy in the treatment of catarrhal inflammations of the respiratory and genito-urinary tracts. The dose of the fluid extract is from 1 to 3 fluidrachms (4–12 Cc.).

Jambul or Jambol Seeds are the seeds of the *Rose apple, Eugenia jambolana* Lam. (*Syzygium J.*—DC.; *Calyptranthes J.*—Willd.), native of the East Indies, where it is largely cultivated for its edible fruit. The bark is similarly used, but is regarded as inferior to the seeds. The seeds are about 1.2 Cm. (½ In.) long and a third as thick, oval, with one end truncated, blackish-gray externally, green internally, hard, heavy, and with little odor or taste. No important constituent has been isolated, and a small quantity of resin, with about 2 per cent. of gallic acid, are the only constituents worthy of note. In the form of a decoction the bark of the root has been recommended for its astringent properties in the treatment of gonorrhœa, leucorrhœa, and chronic diarrhœa.

Guava Leaves, the leaves of various species or varieties of *Psidium,* have quite an extensive domestic use for their astringent and mildly aromatic properties.

Nearly 300 species of *Myrtaceæ,* chiefly in the genus *Eucalyptus, Melaleuca, Eugenia, Myrcia, Calyptranthes, Psidium, Campomanesia,* and *Myrtus,* are recorded as being in use for similar properties to those considered above.

N.

NAPHTHALENUM, *U. S.*—Naphthalene.

Naphthalinum, P. G.; *Naphthalin*, E.; *Naphtaline, Naphthalène*, Fr.; *Naphthalin*, G. Formula, $C_{10}H_8$. Molecular weight, 127.10.

A hydrocarbon obtained from coal-tar, and purified by crystallization.—U. S.

Origin.—Naphthalene was discovered by Garden (1820) in coal-tar oil, and recognized by Reichenbach as resulting from the decomposition of the products of distillation of coal. It has since been obtained from a large number of organic bodies, particularly if the distillation-products are conducted through a red-hot tube, and is a constituent of the petroleum of Burmah. Naphthalene has also been obtained synthetically from the condensation-product resulting from cinnamaldehyde and hippuric acid, by heating it with concentrated hydrochloric acid (*Ber. d. D. Ch. Ges.*, 1902, pp. 217–219).

Preparation.—The fraction of coal-tar oil collected during the distillation of coal tar between 180° and 250° C. (356°–482° F.) gradually deposits a dark crystalline substance, which consists chiefly of impure naphthalene. By treatment successively with sodium hydroxide solution and sulphuric acid certain acid and basic by-products (phenols, aniline, etc.) are removed, and the residue after distillation in the presence of steam, is further purified by repeatedly heating with concentrated sulphuric acid to 188° C. (356° F.) and redistilling. Finally, a white product is obtained which is practically pure naphthalene, but has a tendency to darken when exposed to air and light, owing to slight contamination with some remaining phenols; to remove these the oxidizing effect of a mixture of sulphuric acid and manganese dioxide is resorted to for 15 or 20 minutes at a water-bath heat, and the mixture is then washed with water and sodium hydroxide, and finally resublimed.

Naphthalene recrystallized from alcohol should alone be used for pharmaceutical purposes, and should be kept in well-stoppered bottles.

Commercial naphthalene in the form of balls and flakes is sold under the names of coal-tar camphor and moth-balls.

Properties.—Naphthalene occurs in the form of colorless to white, shining, transparent laminæ or crystalline rhombic plates, having a strong characteristic tarry odor and burning, aromatic taste. At 15° C. (59° F.) its specific gravity is 1.1517, and at 98.8° C. (209.8° F.) 0.9628. It melts at 80° C. (176° F.) to a clear colorless liquid, and boils at 217.2° C. (423° F.), 218° C. (424.4° F.) U. S., and is completely volatilized on continued application of heat, the vapors being inflammable and burning with a luminous sooty flame. Though practically insoluble in water and dilute aqueous solutions of alkalies and acids, naphthalene imparts its odor to the same. Naphthalene volatilizes slowly on exposure to air at ordinary temperatures, and rapidly on application of heat, the vapors possessing antiseptic properties. It is also volatilized with the vapors of volatile liquids. It is soluble in 13 parts of alcohol at 25° C. (77° F.), very soluble in boiling alcohol, and readily soluble in ether, chloroform, carbon disulphide, benzene, and fixed and volatile oils. It is neutral to litmus-paper moistened with alcohol.

On dissolving naphthalene and picric acid together in hot alcohol the two unite, forming on cooling golden-yellow needles having the composition $C_{10}H_8.C_6H_2(NO_2)_3OH$, and yielding all the picric acid to ammonia. Naphthalene yields with chlorine and bromine numerous products of addition and substitution and with sulphuric acid well-defined naphthalene-sulphonic acids. When treated with strong nitric acid, *nitronaphthalenes*—$C_{10}H_7(NO_2)$ and $C_{10}H_6(NO_2)_2$—are generated, which by the action of reducing agents are converted into *naphthylamine*, $C_{10}H_7.NH_2$, which is crystallizable, turns red in the air, and the salts of which yield blue, and finally purple-colored, precipitates with ferric chloride, chromic acid, and other oxidizing agents. By means of diluted nitric acid it is converted into phthalic acid, $C_8H_6O_4$.

Tests.—The ordinary impurities of naphthalene are detected by means of the sulphuric acid test. On shaking a small portion of naphthalene with concentrated sulphuric acid, the acid should remain colorless; nor should it acquire more than a pale-reddish tint, if the mixture be heated for 5 minutes on a water-bath (absence of impurities derived from coal-tar.—U. S. Naphthalene may be identified by treating the substance

with fuming nitric acid, pouring the product into water, and after washing the precipitate with water, boiling it with a solution of equal parts of potassium hydroxide and potassium monosulphide, when in presence of naphthalene a purple color will appear.

Action and Uses.—Naphthalene is employed as an antiseptic in the treatment of gastro-intestinal diseases associated with fermentative changes. It has been recommended in the treatment of enteric fever, but its usefulness in this condition is questionable. It may be employed in intestinal catarrh and in the summer diarrhœa of infants, and in the latter condition its administration is frequently productive of a cure. It has also been recommended as an expectorant in the treatment of chronic bronchial affections. A 10 per cent. ointment may be tried in the treatment of indolent ulcers, eczema, prurigo, and tinea tonsurans. In the hands of the laity it has almost entirely supplanted camphor for the destruction of moths. In the treatment of summer diarrhœa the dose is from $\frac{1}{6}$ to $\frac{1}{4}$ grain (0.01–0.015 Gm.). The ordinary adult dose is from 5 to 10 grains (0.30–0.60 Gm.), in powdered form, best administered in capsules.

NICOLUM.—Nickel.

Nickel, Fr., G.

Symbol, Ni. Bivalent. Atomic weight, 58.3.

Nickel exists in various ores found in Sweden, Germany, and other parts of Europe, and in North America, in Pennsylvania and near Lakes Huron and Superior, and in Canada. It frequently accompanies cobalt, iron, and copper in their ores. It constantly accompanies iron in meteoric stones. The most common nickel ore is the arsenide, NiAs, known as *niccolite;* next in order is *gersdorffite*, $NiS_2.NiAs_2$. The metal was first obtained in 1751, by Cronstedt, from niccolite (*Kupfernickel*). The preparation on the large scale is somewhat complicated, but small quantities can be obtained in the laboratory by reduction of the oxide in a current of hydrogen at high temperature; by strongly heating nickel oxalate; or by reduction of the oxide by carbon at white heat. Canada and New Caledonia (in the Pacific Ocean) produce the largest quantity of nickel ore; that from Canada is smelted mostly in the United States. The New Caledonian ore is a hydrated silicate containing magnesium, and is free from arsenic, cobalt, and sulphur. The purest nickel is obtained by the Mond process, which consists in forming at a moderate heat a gaseous compound with carbon monoxide, $Ni(CO)_4$ (boiling point, 43° C. (109.4° F.)), known as nickel-carbonyl, and decomposing this at a higher temperature with deposition of nickel. The metal occurs in commerce generally in cubes.

Properties.—It is a lustrous white metal, with a slight tinge of yellow, very hard, and capable of a high polish. Impure nickel, containing carbon, is brittle like cast-iron, but when pure or when containing about 1 per cent. of magnesium or manganese it is malleable. The specific gravity of the metal is 8.9, melting-point about that of wrought iron, and in magnetic properties it is a little weaker than iron. It is not changed in the air, dissolves slowly in sulphuric and hydrochloric acids, but readily in nitric acid. It is not advisable to use cooking utensils, as pots, spoons, etc., made of nickel, as the salt and vinegar used in foods dissolve an appreciable amount of nickel, forming nickel salts which are poisonous (Erdmann, *Anorg. Chemie*).

Alloys.—These are extensively used. Argentan or German silver consists of copper, zinc, and nickel. Various copper-nickel alloys are used in coins. Nickel-steel is used for armor-plates.

At present, nickel is extensively used in nickel-plating, a solution of nickel-ammonium sulphate being employed for that purpose.

Reactions.—Nickel, cobalt, and iron are a group of metals which resemble one another somewhat in their chemical behavior. Iron and cobalt form two series of salts, but nickel forms only one set of salts, corresponding to the ferrous salts.

Caustic alkalies precipitate pale-green nickel hydroxide, $Ni(OH)_2$, from solutions of nickel salts, which is soluble, like that of cobalt and copper, in ammonia water. Heated to redness, it gives a greenish oxide, NiO. There is also a black oxide, Ni_2O_3, but it does not give nickelic salts with acids. Ammonium sulphide gives black nickel sulphide, NiS, similar to cobalt sulphide, scarcely acted on by 5 per cent. hydrochloric acid. Nickel salts give a reddish-brown bead with microcosmic salt in the oxidizing flame when hot, pale-yellow when cold, while cobalt gives a blue bead. Cobalt and nickel resemble each other so closely that it is not a simple matter to separate them in solution, but this can be done by a few reactions. One method, readily carried out, is to add barium or

calcium carbonate to a neutral solution, and then bromine water in excess. Cobalt is precipitated as black cobaltic oxide, which is filtered off after 10 minutes' standing. From the filtrate barium is removed by sulphuric acid, and nickel is determined electrolytically (modified Rose's method by R. L. Taylor, *Chem. News*, 1902, p. 269). In general, crystallized nickel salts are green while the anhydrous salts are yellow.

SALTS OF NICKEL.

Nicoli Bromidum.—*Nickel bromide*, E.; *Bromure de nickel*, Fr.; *Nickelbromür*, G. $NiBr_2 3H_2O$.—It is prepared by digesting nickel with bromine and water, or by dissolving nickel carbonate in hydrobromic acid and crystallizing. It crystallizes in green deliquescent needles or prisms, which are soluble in alcohol, ether, and water; the latter solution on exposure is decomposed, depositing nickel hydroxide. The physiological action of nickel bromide is analogous to that of sodium bromide. It is more irritant to the stomach, however, and because of this fact should be given largely diluted. The dose is 10 grains (0.60 Gm.), corresponding to 30 grains (2 Gm.) of the sodium salt. It is best administered as an effervescing draught. A powder prepared by mixing the salt, tartaric acid, and sodium bicarbonate, may be triturated with alcohol, granulated, and dried. This may then be added to water and swallowed during effervescence.

Nicoli Carbonas.—*Nickel carbonate*, E.; *Carbonate niccolique*, Fr.; *Nickelkarbonat*, G.—It is pale-green or blackish-green, of variable composition, and is prepared by precipitating the solution of a nickel salt with sodium or potassium carbonate. This salt was formerly employed in the treatment of anæmia in doses of 2 grains (0.12 Gm.), several times daily. It is probably of little therapeutic value.

Nicoli Chloridum.—*Nickel chloride*, E.; *Chlorure de nickel*, Fr.; *Nickelchlorür*, G.—The hydrated salt is green, very deliquescent, and contains $6H_2O = 45.4$ per cent. The anhydrous chloride is yellow, or, in the presence of cobalt, has a green tint; it sublimes in yellow lustrous scales.

Nicoli Sulphas.—*Nickel sulphate*, E.; *Sulfate de nickel*, Fr.; *Nickelsulfat*, G. $NiSO_4 \cdot 7H_2O$.—Nickel sulphate may be prepared by dissolving pure nickel carbonate in diluted sulphuric acid, concentrating the solution, and crystallizing at or below 20° C. (68° F.), or precipitating it with alcohol. The salt is extensively manufactured on the large scale from impure carbonate, the process involving the separation of other metals, like arsenic, iron, copper, and cobalt. The salt forms either a green crystalline powder, or it is generally seen in emerald-green transparent rhombic prisms, which effloresce on exposure, losing 1 molecule of H_2O, and being at the same time converted into an aggregation of octahedral crystals. A salt containing $6H_2O$ is also obtained by crystallization from an acid solution at above 20°C. (68° F.). The salt has a sweetish and styptic taste and a slight acid reaction, is soluble in about 3 parts of water at 15° C. (59° F.), insoluble in alcohol and ether, and loses at 103.3° C. (218° F.) 38.5 per cent. (the salt with $6H_2O$, 34.2 per cent.) of water, the remaining molecule of water being expelled above 250° C. (482° F.). The solution of nickel sulphate, on being mixed with a saturated solution of ammonium sulphate in excess, gives a precipitate of *nickel-ammonium sulphate*, $(NH_4)_2Ni(SO_4)_2 \cdot 6H_2O$. This salt is blue-green, almost insoluble in solutions of alkali sulphates, but soluble in about 8 parts of water; it, like the sulphate, is largely used for the electroplating of iron, copper, and other metals with nickel.

NITROGENII MONOXIDUM.—Nitrous Oxide.

Laughing-gas, E.; *Oxyde nitreux, Protoxyde d'azote*, Fr.; *Stickstoffoxydul, Lachgas*, G.
Formula, N_2O. Molecular weight, 43.74.

Origin.—Nitrous oxide was first obtained by Priestley (1772), by acting upon nitric oxide with moist iron filings; he also noticed that ignited bodies burn in this gas with a brighter flame than in atmospheric air. The composition of the gas was determined by Deimann and Troostwijk (1793), who prepared it from ammonium nitrate. H. Davy (1800) observed its exhilarating effects.

Preparation.—Ammonium nitrate which is absolutely free from chloride is gradually heated to about 200° C. (392° F.), when decomposition commences, and the heat may be slowly increased, but should not go above 240° C. (464° F.). The salt yields then water and nitrous oxide: $NH_4NO_3 = 2H_2O + N_2O$. If the temperature is too high, other products are formed, as nitric oxide, nitrogen, and ammonia. To remove possible impurities, the gas is passed through solutions of potassium hydroxide and ferrous sulphate. Nitrous oxide occurs in the market compressed in steel cylinders.

Properties.—Nitrous oxide is a colorless gas, of a very slight agreeable odor and a sweetish taste. It has the specific gravity 1.6 (Dalton), and a liter of it at 0° C. (32°

F.) weighs 1.97 Gm. It is not inflammable, but supports the combustion of ignited bodies, which burn more vigorously than in the open air. By the aid of pressure and cold it may be condensed into a thin, very mobile, colorless liquid, which at a temperature of about —100° C. (—148° F.) congeals to colorless crystals. The gas is soluble in water, alcohol, ether, volatile and fixed oils.

Nitrous Oxide Water.—The solubility of nitrous oxide in water has been determined by Carius (1855) as follows: Water absorbs at a barometric pressure of 760 Mm. and a temperature of 0° C., 1.3052; 5°, 1.0954; 10°, 0.9196; 15°, 0.7778; 20°, 0.6700; 25°, 0.5963 measures of the gas. Such an aqueous solution, prepared under a pressure of about 5 atmospheres, has been employed under the name of *oxygenous aërated water.*

Action and Uses.—When nitrous oxide gas is inhaled in small amounts, it produces mental disturbances with hilarity, which give it the name "laughing-gas." Used in concentrated form, as in medicine and surgery, it does not cause these symptoms if properly inhaled, but after a few deep inspirations a flush followed by a deadly pallor overspreads the countenance, unconsciousness comes on almost instantaneously, and the surgical operation can then be performed without pain. The gas is not suitable for any but brief and minor operations, as its effects are too fleeting. For this reason, and also because of its lack of producing after-effects, it is popular with dentists for the extraction of teeth, and with some surgeons to produce primary anæsthesia, which can be readily continued by immediately employing ether or chloroform. Nitrous oxide is the safest anæsthetic known, its death-rate being less than 1 in 500,000.

As nitrous oxide raises arterial pressure, and so places stress upon the heart and blood-vessels, it ought not to be used in persons who have fatty heart or atheroma of the blood-vessels, as it may cause heart-failure or apoplexy. As the jaws may be firmly closed when the patient is under the effects of the drug, dentists usually place a cork between the teeth to keep the jaws apart, and tie a string to the cork to prevent its being drawn into the glottic opening should the patient's jaws relax so that the cork is freed from pressure.

Nitrous oxide gas causes anæsthesia by a direct influence on the central nervous system, and by virtue of the asphyxiation it produces.

NITROGENIUM.—Nitrogen.

Stickstoff, Stickgas, G.; *Azote,* Fr.

Symbol, N (French, Az). Valence in nearly all compounds either 3 or 5. Atomic weight, 13.93.

The occurrence of nitrogen in the free state and in combination has been noted under Aër, Acidum Nitricum, Aqua Ammoniæ, and Potassii Nitras. In the putrefactive changes of nitrogenous organic substances the nitrogen is not all converted into ammonium compounds and nitrates, but a portion escapes in the uncombined state. Under the influence of certain nitric acid destroying bacteria, large quantities of the nitrogen which is in combination in manures often escape into the air in the free state.

Nitrogen may be obtained from the atmosphere by absorbing the oxygen, for which various substances may be used, such as copper turnings heated to redness, yellow phosphorus, alkaline solution of pyrogallic acid. Such atmospheric nitrogen, however, is not pure, since it contains about 1 per cent. of argon, which cannot be absorbed. Pure nitrogen can be obtained by decomposing ammonium nitrite by heat: $NH_4NO_2 = 2H_2O + N_2$; or by passing chlorine into an excess of ammonia water: $8NH_3 + 6Cl_2 = 6NH_4Cl + N_2$.

Properties.—Nitrogen is a colorless, odorless, tasteless gas, slightly lighter than air, density (air = 1) 0.967, and weight of 1 liter at 0° C. and 760 Mm. barometric pressure 1.2507 Gm. The weight of atmospheric nitrogen under like conditions is 1.2572 Gm. 100 volumes of water at 10° C. (40° F.) dissolve 1.61 volumes of nitrogen; in alcohol it is slightly more soluble. Under great pressure and a low temperature it liquefies, the liquid having the boiling-point —194° C. (—317.2° F.) at atmospheric pressure. It has also been solidified. Nitrogen does not support combustion or respiration, hence the French name *azote* (from *a*, and *ζωτικός*, life) and the German *Stickstoff* (from *sticken*, to choke). In the atmosphere it serves as a diluent of the oxygen. It is very inert, having very little affinity for other elements, except in the case of a few substances, as magnesium, lithium, boron, silicon, and a few others, with which it combines readily at red heat, forming *nitrides;* for example, Mg_3N_2, Li_3N. Indirectly, however, it gives

rise to a number of nitrogen compounds, such as the oxides, nitric and nitrous acids, ammonia, which are described elsewhere. Nitrogen is essential to plant-life, but plants can, as a rule, assimilate it only when in the form of ammonium salts or nitrates. Hellriegel discovered the highly interesting and important fact that the roots of leguminous plants, by the aid of certain bacteria, located in nodules on the same, can assimilate free atmospheric nitrogen. Thus we have a connecting link between nitrogenous compounds which are the source of the nitrates and ammonia of commerce, and atmospheric nitrogen. At the present time nitrogen of the air is also converted directly into nitric acid by bringing air into intimate contact with a number of extremely high-tension electric arcs. This process, devised by Bradly and Lovejoy, is carried out at Niagara Falls, and bids fair to have commercial value.

Determination of Nitrogen.—Various methods are available which will be described in a general way. For details as to quantities and manipulations, reference must be had to extensive works on chemistry, such as Fresenius' *Quantitative Analysis*, or to *Bulletin No. 46*, Division of Chemistry, U. S. Department of Agriculture.

Dumas Method.—Applicable to all nitrogen compounds without exception. A weighed quantity of the substance is heated to redness in a hard-glass tube, with copper oxide or lead chromate, or a mixture of both. The nitrogen passes off free and also as oxides. To reduce the latter to free nitrogen, the vapors are passed over a spiral of copper gauze, heated to redness, lying in the forward part of the combustion-tube. The nitrogen gas is finally collected in a tube over caustic alkali and measured.

Will-Warrentrapp Method.—Applicable only to derivatives of ammonia, and not to derivatives of nitric acid. It was formerly used to determine the protoid nitrogen in foodstuffs, but for this purpose is now replaced by the Kjeldahl method. The substance mixed with soda-lime is heated in a tube, whereby nitrogen is liberated as ammonia, which is passed into a measured volume of decinormal sulphuric acid and the excess determined by titration. From the quantity of ammonia found the amount of nitrogen in the substance is calculated.

Kjeldahl Method.—This method is in very general use, especially at agricultural stations, where nitrogen in fertilizers and food-products is frequently determined. It depends on the fact that when bodies, like albumin, which are derivatives of ammonia, are boiled with concentrated sulphuric acid to complete decomposition, the nitrogen is converted into ammonia, which, with the acid, forms ammonium sulphate. The decomposition is performed in a pear-shaped flask with a long neck. In some instances, in order to facilitate the reaction, potassium permanganate, or mercury or potassium bisulphate, is added. After the action is over, the contents of the flask are diluted, caustic alkali is added in excess, and the ammonia distilled into decinormal sulphuric acid and determined as above. In this manner nitrogen can be determined in: (1) amido compounds, ammonium bases, most alkaloids, bitter principles, all protein and related bodies; (2) nitrates, which must, however, be converted into nitro compounds by addition of phenol or salicylic acid to the sulphuric acid; the nitro compounds are reduced to amido derivatives, which are then decomposed as described above. The method is not applicable to inorganic nitrites, hydrazo, diazo, and azo compounds, and many cyanides. In the case of albumins, the quantity present is found by multiplying the amount of nitrogen by the factor 6.25.

Ulsch Method.—This has almost entirely displaced the Kjeldahl method in the case of nitrates. 1 Gm. of the nitrate is dissolved in 50 Cc. of water in a 800 Cc. flask, 10 Gm. of reduced iron, and 20 Cc. of sulphuric acid (1 of acid to 2 of water) are added, the flask covered with a watch-crystal, and after 5 minutes heated to boiling for about 8 minutes. The cover is then rinsed into the flask, 150 Cc. of water and 60 Cc. of caustic soda solution (specific gravity 1.25) are added, and the whole distilled until about one-half the volume or more has passed over into a receiver containing an excess of normal or half-normal acid, the excess being determined by back titration, using Congo-red as indicator.

Nitragin.—This is a name applied to cultures of the bacteria (*Rhizolicum Leguminosarum* or *Bacterium radicicola*) which are found in the nodules on the roots of leguminous plants. The cultures are used as a fertilizing medium.

NUX VOMICA, *U. S.*, *Br.*—Nux Vomica.

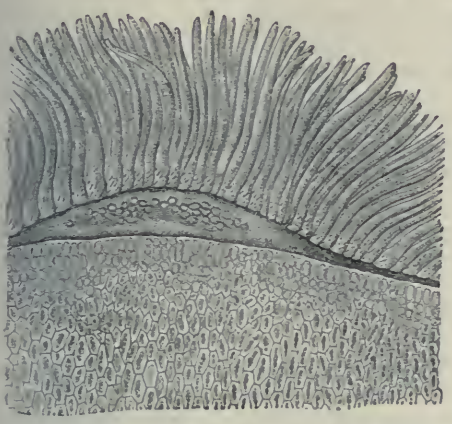
Semen strychni, P. G.; *Semen nucis vomicæ.—Poison-nut, Dog-buttons, Quaker buttons*, E.; *Krähenaugen, Brechnuss*, G.; *Noix vomique*. Fr. Cod.; *Noce Vomica*, It.; *Nuez vomica*, Sp.; *Noz Vomica*, Port.

The seed of *Strychnos Nux-vomica* L. (Fam. *Loganiaceæ*), yielding, when assayed by the process given below, not less than 1.25 per cent. of strychnine.—U. S.

Nux vomica is official in all pharmacopœias.

Origin.—From a small straggling tree of India, Ceylon, Cochin-China, and northern Australia. The fact that the commercial seeds exhibit well-marked, though slight differences in appearance, corresponding to quantitative differences in composition, has led to a question as to their origin from different species or varieties of the plant, a question which has not been definitely settled. The seeds, numbering from 1 to 4, usually with a few undeveloped ones, occur imbedded in a white gelatinous pulp, in a fruit resembling a small orange in form, size, and color. Notwithstanding the oft-published statement that this pulp is harmless, and even edible, Dunston and Short have shown that, when dry, it contains about 1.5 per cent. of strychnine and 1 per cent. of brucine, together with 5 per cent. of the crystalline glucoside loganin ($C_{25}H_{34}O_{14}$), and that it is promptly fatal to animals, with the characteristic symptoms of strychnine-poisoning. The seeds are simply washed free from the pulp and dried in the sun.

FIG. 284.



Nux vomica: section through hilum and albumen (× 65).

Description.—About 1.5 to 2.5 Cm. ($\frac{3}{5}$ to 1 In.) broad, lenticular, but irregularly curved, with an elevated central spot upon one or both sides and upon one side a low ridge (the raphe) running thence to the edge; externally gray, greenish-gray or light-yellowish-gray, silky in luster and to the touch, densely clothed with a coat of closely appressed, shining hairs; internally hard, very tough, somewhat translucent, consisting of 2 disks of perisperm which enclose a thin circular cavity and the embryo which has small heart-shaped, palmately nerved cotyledons; inodorous and intensely and persistently bitter.

Since the content of active constituent in Nux vomica corresponds closely with certain physical differences, their careful selection is a matter of high importance. The best

FIG. 285.

Nux vomica: surface with raphe; longitudinal section, showing albumen and embryo; and transverse section, showing central cavity.

quality, here described, usually corresponds with the Ceylon variety, which produces larger seeds and fewer in a fruit, the above-named authors having shown that the quality of the seed varies proportionally with such difference in their occurrences. The best seeds are known by their greater breadth (nearly or quite an inch), the thinness of their edge, their lightness of color and greater silkiness of surface and the prominence of the hilum.

So far as adulteration is concerned, there is nothing which in the least resembles Nux Vomica in the entire condition. The powdered article is not only subject to adulteration and to the presence of an undue amount of hairs in some lots, but, unless carefully and evenly powdered, is not apt to yield readily its active constituent to the extracting menstruum. It should therefore be purchased wholly upon its guaranteed assay, yielding, according to the official requirement, not less than 1.25 per cent. of strychnine.

Constituents.—From the standpoint of their activity, the important constituents of Nux Vomica are the two alkaloids strychnine and brucine, the characters of which will be fully discussed under the title STRYCHNINA. Their percentages, both absolutely and relatively to one another, vary most widely. Of total alkaloid, the amount is ordinarily

stated to be 1½ to 3 per cent., but Dunston and Short's analyses indicate much more, namely 4 to 5 per cent., and in one case nearly 5½ per cent. The probability is that, owing to the difficulty of its extraction, analysts ordinarily fail to obtain full results, and that at least 3 to 4 per cent. must be considered as existing in seeds of fair quality. Of this amount, the strychnine is ordinarily from a third to nearly a half, the remainder being brucine. From a pharmaceutical point of view, the fixed oil is important, being quite troublesome. The alkaloids are found combined with *igasuric* ("strychnic") acid, which is similar to tannic acid, occurring as an amorphous, yellowish-white, strongly acid and somewhat astringent mass, its solution colored dark-green by ferric salts, precipitated yellow by lead acetate, and rapidly reducing an ammoniacal solution of silver. The tough, horny qualities of the perisperm are considered to be due to proteids, of which about 11 per cent. is present. The presence of a small amount of loganin has been proved. Other alkaloids which have been reported, especially "igasurine," have proved to be mixtures, though the presence of small amounts of undetermined alkaloids is regarded as probable. The presence of traces of copper in Nux Vomica preparations has been frequently recorded, but its occurrence as a natural constituent of the seeds has been shown to be improbable.

Assay of Nux Vomica.—The U. S. P. requires that nux vomica shall contain not less than 1.25 per cent. of strychnine, which may be determined as follows: Place 20 Gm. of nux vomica, in No. 60 powder, in a 250 Cc. flask, and pour over it 200 Cc. of a mixture of ether 137.5 Cc., chloroform 44 Cc., alcohol 13.5 Cc., and 10 per cent. ammonia water 5 Cc. Cork well, shake frequently during an hour, and let stand in a cool place overnight. Decant into a measuring cylinder 100 Cc. of the ethereal liquid (representing 10 Gm. of nux vomica) and pour this into a separator, preferably of globular shape. Now wash out the cylinder with a little chloroform, and add this to the separator. Next add to the contents of the latter 15 Cc. of normal sulphuric acid, and shake moderately during 1 minute, being careful to avoid emulsification, and after allowing the liquids to separate completely, draw off the entire acid liquid into another separator or a beaker. Repeat this treatment with 5 and 3 Cc. more of normal sulphuric acid, and after mixing all the acid solutions, pour them into a separator. If a drop of the last acid solution yields a precipitate with mercuric-potassium iodide test-solution, repeat the washing of the ethereal liquid with 5 Cc. more of normal sulphuric acid. To the combined acid solutions in the separator, add a small piece of red litmus-paper, 25 Cc. of chloroform, and then an excess of ammonia water, shaking until all the alkaloids have been dissolved in the chloroform. Draw off the latter into a 100 Cc. flask, and repeat the shaking-out process with two additional portions of 15 Cc. each of chloroform, adding the latter to that already in the flask. Evaporate the combined chloroformic solutions in the flask until the alkaloidal residue is dry. Dissolve the residue in 15 Cc. of 3 per cent. sulphuric acid by the aid of water-bath heat, and cool the solution to ordinary temperature. To this solution add 3 Cc. of a previously cooled mixture of equal volumes of nitric acid (specific gravity 1.41) and distilled water, and after rotating a few times set the liquid aside for exactly 10 minutes, shaking it gently 3 times during this interval. The resulting red liquid is transferred to a separator containing 25 Cc. of a 10 per cent. solution of sodium hydroxide, the flask being washed 3 times with very small quantities of distilled water, which is then added to the contents of the separator. If the liquid is not quite turbid, add 2 Cc. more of the 10 per cent. sodium hydroxide solution. Now add 20 Cc. of chloroform to the liquid in the separator, and shake well by a rotating motion for a few minutes, let separate and draw off the chloroform through a small filter, wetted with chloroform, into a beaker. Repeat this treatment twice, using 10 Cc. of chloroform each time, and draw both portions off into the beaker through the same filter. Finally, wash both filter and funnel with 5 Cc. of chloroform, and then evaporate all the chloroform on a water-bath very carefully to avoid decrepitation. To the residual alkaloid, add 6 Cc. of tenth-normal sulphuric acid, 5 drops of iodeosin test-solution, about 80 Cc. of distilled water, and 20 Cc. of ether. When all the alkaloid is dissolved, titrate the excess of acid with fiftieth-normal potassium hydroxide solution until the aqueous liquid just turns pink. Divide the number of Cc. of fiftieth-normal potassium hydroxide solution used by 5, subtract this number from 6 (the 6 Cc. of tenth-normal sulphuric acid taken), multiply the remainder by 0.033, and this product by 10, which will give the percentage of strychnine in the sample of nux vomica.

Pharmaceutical Preparations.—Extract of Nux Vomica, Fluidextract of Nux Vomica, Tincture of Nux Vomica, U. S. P.

Action and Uses.—When nux vomica is taken in poisonous dose, it produces nervous excitability, followed by violent tetanic or tonic convulsions, in which the muscles of the body are almost universally thrown into rigid contractions. These contractions bend the body in the direction of greater strength, and as the muscles on the posterior surface are usually stronger than those on the anterior surface, the patient takes the attitude

which is known as opisthotonos, often resting during the convulsive seizure upon his occiput and heels, the middle portion of the body not touching the bed. After the convulsive seizure has lasted a varying length of time, from a few seconds to a minute or more, the muscles undergo complete relaxation, and the individual lies before us in a condition of profound exhaustion because of the violence of the convulsive seizures through which he has just passed. During the convulsion respiration is completely, or almost completely, arrested by the fixation of the respiratory muscles, and if the convulsive seizure lasts for a long time death may result from what is known as cramp asphyxia. In other words, the respiratory muscles are fixed for so long a period that air is not drawn into the lungs and death ensues. In the majority of instances, however, death comes quite as much from exhaustion and the violence of the nervous storm as it does from cramp asphyxia, although the interference with respiration produces marked cyanosis in each attack. The circulation, under the influence of these doses, is not directly affected to any extent, but the action of the heart and the condition of the blood-vessels, and the blood which is circulating in them, is necessarily modified very greatly by the violence of the muscular contractions. If death does not ensue in the first or second convulsion, after a time the convulsions may become slightly less severe in character. This decrease in the severity is not due necessarily to diminution in the activity of the drug, but to the fact that the motor nerves which carry the impulses from the spinal cord to the muscles become exhausted because of the severity of the strain which is thrown upon them. The mind is unaffected by the drug, and intellection only becomes disturbed as the result of exhaustion or cyanosis. If strychnine is given in massive doses and life maintained by means of artificial respiration, the peripheral ends of the motor nerves become paralyzed. Such an effect, however, never occurs in man, for death takes place before the poison has time to produce this effect. As the convulsive seizures of strychnine-poisoning are not brought into existence except by means of some peripheral irritation, it is exceedingly important that all noises should be avoided, and that the patient should not be touched except when absolutely necessary, since the whole nervous system is in a condition of hyperexcitation.

The treatment of the poisoning, if the patient is seen early enough, consists in the administration of an emetic. If there is reason to believe that the poison has already been absorbed in sufficiently large quantities to cause immediate danger of a convulsive seizure, the patient should be chloroformed, and while under the influence of chloroform should receive by the rectum 60 grains (4 Gm.) of potassium bromide and 40 grains (2.6 Gm.) of chloral in starch water, and should be kept under the chloroform until sufficient time has elapsed for these drugs to be absorbed from the rectum, and act as physiological antagonists to the influence of the strychnine upon the motor tracts of the spinal cord. If the patient is already in a convulsion, little can be done unless he is breathing, in which case amyl nitrite should be held under his nose in order to produce speedy muscular relaxation. Before its transient effects pass off, the influence of chloroform should be produced. If the patient cannot breathe because of the convulsive seizure, 5 to 10 minims of amyl nitrite may be injected hypodermically. It is a noteworthy fact that the convulsions of strychnine-poisoning are characterized by periods of complete relaxation, whereas those of tetanus are usually characterized by only partial relaxation.

The muscles of the face, both in tetanus and strychnine-poisoning, may be so contracted as to produce a curious expression, which is known as the "risus sardonicus."

In medicinal dose nux vomica and its alkaloid, strychnine, act as powerful excitants and stimulants to nervous protoplasm throughout the body, increasing the acuity of the nerves of sense; not only those of touch, but also those of hearing and sight. For this reason strychnine is largely employed for the purpose of stimulating nervous protoplasm which is incapable of performing its normal function as a result of various forms of depression and paralysis. It ought never to be employed during the stage of inflammation in any nervous affection, but after the acute inflammatory process has passed by it often proves itself a valuable remedy. Ophthalmologists employ it largely for the purpose of combating blindness which is due to disease of the optic nerve. While in many instances it cannot necessarily be of any permanent value, it is nevertheless often of benefit. It is also employed in cases of insufficiency of the ocular muscles. In all these affections it is commonly given in rather large doses, and is not infrequently administered hypodermically. It is needless to add that conditions of overexcitability in the nervous system contraindicate its employment. When administered by the stomach, it is often used as a bitter tonic for the purpose of aiding digestion, and, to some extent, for over-

coming constipation by giving tone to the alimentary canal. Because of its action in this manner it is largely employed as a tonic in convalescence and in exhausting fevers like typhoid fever and pneumonia. Strychnine has probably no direct stimulating influence upon the circulatory system, the increased force and activity of the heart under its influence being largely dependent upon the increased nerve-supply of the circulatory system under the powerful stimulant influence of the strychnine upon nervous protoplasm. The drug, nevertheless, is highly regarded by physicians as a most important remedy in the treatment of collapse and shock, and to tide the patient over critical periods in acute and chronic diseases. It ought not to be given for a long period of time as a circulatory stimulant. When it is employed over a long period of time, it is apt to produce great nervous and mental irritability, and a rapid, feeble pulse. This is particularly apt to be the case in old persons and in individuals suffering from asthenia.

Strychnine is one of the best stimulants for the respiratory centers that we have, and is largely employed as a respiratory stimulant in all conditions where such an action is desired.

As is the case with most vegetable alkaloids, the drug is oxidized in the body unless it is given in excess, when it is eliminated as strychnic acid.

Powdered nux vomica beans are sometimes given in the dose of 1 to 2 grains (0.06–0.12 Gm.). The dose of the solid extract of nux vomica is from $\frac{1}{8}$ to $\frac{1}{4}$ grain (0.008–0.015 Gm.); of the fluidextract, from 1 to 5 minims (0.05–0.30 Cc.); of the tincture, from 5 to 20 minims (0.30–1.30 Cc.). The dose of strychnine, the chief alkaloid, is from $\frac{1}{40}$ to $\frac{1}{20}$ grain (0.0015–0.003 Gm.). The sulphate of strychnine is usually employed. (See STRYCHNINÆ SULPHAS.)

Allied Products.—Nux Vomica leaves are used to a slight extent by the natives of India and have been examined by Hooper. These leaves are rather stoutly and shortly petioled, range from 6 to 12 Cm. (2½ to 5 In.) long, are oval to rotund-oval, rounded or narrowed at the base, acute at the apex, entire, smooth, strongly 3-, or occasionally 5-nerved and thickish. They yield about 0.3 per cent. of brucine and have proved very poisonous to cattle. Brucine is also present in large quantity in the bark and wood. Thus far, strychnine has not been detected in leaves, bark, or wood.

The genus *Strychnos*, L., contains nearly 100 species, distributed through most tropical countries. They are characterized generally by the possession of violently poisonous constituents. Of the Old World species, the seeds have received most attention, while the barks of the New World species have been more studied. This is due doubtless to the extensive use of these barks in the manufacture of arrow poisons. For an account of these see CURARE.

Ignatia, U. S. 1880 (*Semen Ignatiæ*, *Faba Ignatii*, *Bean of St. Ignatius*, E.; *Ignazbohne*, G.; *Fève de Saint-Ignace*, Fr. Cod.; *Fève Ignasurique*, Fr.; *Haba de San Ignacio*, Sp.), is the dried ripe seed of *Strychnos Ignatia* Lindl. (*S. Philippinensis* Blanco; *Ignatiana Philippica* Lour.). It is derived from a plant and fruit very similar to those yielding Nux Vomica, but native of the Philippines, and naturalized in Cochin-China. It is usually a little more than 2.5 Cm. (1 In.) in length and a half to two-thirds as broad, irregularly and angularly oval-ovate, the angles rounded or blunt, the hilum in a small depression on one of the edges, the dull reddish-gray or brownish, rarely blackish, surface somewhat granular or papillose, occasionally bearing remains of the covering of light-brown silky hairs; heavy and of bony hardness, the fracture irregular and granular; translucent in thin fragments, an irregular cavity near one end, into which the embryo projects, its radicle rather long, its cotyledons oblong-ovate and acute; almost inodorous and of a very bitter taste.

FIG. 286.

Ignatia: vertical section of seed.

It is said that the powder of Ignatia can be readily distinguished from that of Nux Vomica by the occurrence of its, relatively few, hairs in clusters instead of singly as in Nux Vomica. The constituents of Ignatia are very similar to those of Nux Vomica. The percentage of total alkaloid is usually smaller than in Nux Vomica. Testimony concerning the relative proportion of the two alkaloids is very contradictory, due probably to their imperfect separation in the assays made. Ignatia has been somewhat used in the same way as Nux Vomica, but it is much more expensive. Its introduction to the Pharmacopœia in 1880 did not result in bringing it into extended use.

Tieute seeds are produced by *S. Tieute* Lesch, of Java, and are quite similar in appearance to Nux Vomica, though smaller and whiter. The seeds are little used, but the root-extract is employed in the preparation of the poison known as *Upas Tieute* or *U. Radja*.

Akazgine is an alkaloid obtained by Fraser from a shrubby species of *Strychnos* used in equatorial Africa under the names *Akazga*, *Ikaju*, *Quai*, or *Boundou*. Other authors found an alkaloid having the color-reactions of strychnine.

Hoang-nan is the bark of the Chinese species *S. Malaccensis* Benth. (*S. Galthieriana* Pierre), and contains both strychnine and brucine. The same constituents occur in the wood of *S. colubrina* L., the *Snake-wood tree*, the wood an article of commerce in India under the name *Lignum colubrinum*. In India, the seeds of *S. potatorum* L. are used under the name of *Clearing-nuts* for clearing muddy water, as well as for diabetes and as an emetic. In 1871, they were imported into the United States under the name *Indian gum-nuts*. They are sub-globose, brownish-gray, and insipid. In South America, the bark of *S. Pseudochina* St. Hil. has been used as a cinchona-substitute.

NYMPHÆA.—Water Lily; Pond Lily.

Sweet-scented or *Fragrant water lily*, *Water nymph*, E.; *Seerose*, *Wasserlilie*, G.; *Nénuphar*, *Lune d'eau*, Fr.; *Ninfea*, *Ninfa*, Sp.

The rhizome of *Castalia odorata* (Dryander) Woodv. et Wood (*Nymphæa o.* Dryander; *Castalia pudica* Salisb.—Fam. *Nymphæaceæ*).

Origin.—The white water-lilies are too well known to require a description. The species here named is more common in eastern North America, becoming gradually replaced westward by the larger and little fragrant *C. tuberosa* (Paine) Greene. The European species is *C. alba* (L.) Lyons (*Nymphæa a.* L.; *C. speciosa* Salisb.). The long-continued misapplication to these plants of the name *Nymphæa*, which had previously been given, and therefore properly belongs, to the yellow pond-lilies, has caused much confusion.

Description.—A very long rhizome, occurring in pieces of irregular length, or more usually in transverse slices, 2.5 to 7 Cm. (2 to 3 In.) thick, cylindraceous, roughly annulate and heavily wrinkled, bearing on the upper side broad, sub-circular or oblong leaf-scars and underneath remnants or scars of thick fleshy roots; dark-brown or blackish externally, yellowish-white internally, very spongy and light, the wood-bundles irregular; nearly odorless, of a mucilaginous, bitter, and astringent taste.

Constituents.—The constituents are very imperfectly known. Resin, tannin, starch, and gum have been reported, but do not account for the bitter taste, which in related species is due to alkaloids.

Action and Uses.—The American water lily, because of its astringency, may be tried as a remedy for diarrhœa, dysentery, and leucorrhœa. The European species was formerly employed in the East as an anaphrodisiac.

Other Nymphæaceæ.—This, the *Water-lily family*, contains 8 genera and about 50 species, of great beauty and of universal interest, the *Victoria regia* Lindl. producing one of the largest of known flowers. The rhizomes of a number of species are employed like that above described. That of *C. alba* was formerly a highly prized aphrodisiac, apparently without good reason. It contains an amorphous alkaloid. The flowers of this, as of *C. odorata*, have also been employed. The *Yellow pond-lilies*, the true *Nymphæas*, have also been employed. *N. lutea* L. (*Nuphar luteum* Sibth. et Sen.; *Nymphozanthus vulgaris* Rich.), the European *Yellow pond-lily*, *Flatter-*, *Spatter-*, or *Can-dock*, *Water-blab*, or *Water coltsfoot*, has been chiefly employed. The rhizome is very similar to that above described, but is even thicker and coarser. It contains the white, amorphous alkaloid *nupharine*, soluble in alcohol. Its uses are similar to those of the Water-lily. There are several American species, some of them formerly regarded as identical with the European, which have been similarly employed, especially *N. advena* Solander, the common names similar to those of the European, also called *Cow-*, *Horse-*, *Dog-*, *Frog-*, *Bull-head-*, or *Beaver-lily*, *Beaver-root*, *Muskrat-root*, etc. *Castalia Lotus* (L.) Rusby (*N. Lotus* L.; *C. mystica* Salisb.—*Lawas* or *Taylalo* in the Philippines) has had very many uses, mostly based upon superstition, but also those of the species above considered. In China, the root-stock of *Euryale ferox* Salisb. (*Anneslea speciosa* Roxb.) is used as an astringent and tonic under the names *Kien-shih* and *Ki-t'u*. The leaves of *Brasenia purpurea* (Mx.) Casp. (*Hydropeltis p.* Mx.; *Brasenia Schreberi* Gmel.; *B. peltata* Pursh.), the common *Water-shield*, *-target*, or *-jelly*, *Deer-foot*, *Frog-leaf* or *Water-leaf*, of almost world-wide distribution, in stagnant waters, are used in many countries in the treatment of phthisis, also for dysentery. The rhizomes of the several species of *Nelumbo*, Adans., bear fleshy-thickened portions, rich in starch, for which reason they have been much used as foods. Their seeds, under the name *Water-bean*, have also been used as food, those of the North American *N. lutea* (W.) Pers. (*American lotus*, *Water chinquapin*, *Duck acorn*, *Water-nut*, *Waukapin*, or *Yoncopin*) having been an important food among the North American Indians. In India, the similar seeds of *Euryale ferox* Salisb. are used for food in the same way as those of Nelumbo. Church reports the following constituents: starch, 73.3 per cent.; fat, 0.97 per cent.; albuminoids, 12.8 per cent.; fiber, 0.3 per cent.; ash, 0.4 per cent. What portion of these nutrients is digestible is not stated.

O.

OLEA.—Oils.

The term oil, or rather its equivalent, appears to have been applied originally to the liquid fats from the olive and other vegetable fat-producing substances. Its immiscibility with water, its unctuous touch and fatty consistence were early noticed. By extension the term oil was made to include even water-soluble substances which in consistence resembled the oils, as, for instance, oil of vitriol or sulphuric acid. With the classification of all natural objects and seminatural products according to the three natural kingdoms, oils were grouped according to their source as mineral oils, vegetable oils, and animal oils. The term mineral oil is restricted almost entirely to petroleum and related products, which have nothing in common with the inorganic world but their name, *oleum petræ*, rock oil. The classification into vegetable and animal oils, although these terms are in good use to-day in technology and commerce, has been largely dropped with the development of organic chemistry during the past century. The designation of liquid fats or fatty oils as fixed oils serves the purpose of distinguishing these substances at once from other bodies, also known as oils but which are characterized by their volatility and on this account called volatile oils.

OLEA INFUSA.—Infused Oils.

Olea cocta.—Oleoinfusions, Oleols, E.; *Oléolés, Elæolés, Huiles médicinales,* Fr.; *Gekochte Oele,* G.

This class of preparations was formerly much used, especially in Europe, and several of them have retained a place in the pharmacopœias of the Continent. They are made from flowers or herbs, either aromatic or narcotic, by digesting 1 part of the dry drug in 10 parts of olive oil, or by moistening the ground drug with alcohol 1 part, allowing the mixture to stand in a covered vessel for several hours, then adding the oil and warming on a water-bath until all alcohol has been dissipated, after which the mixture is expressed and the oil filtered. In the manner last stated the P. G. directs *Oleum hyoscyami* (*Infused oil of hyoscyamus,* E.; *Bilsenkrautöl,* G.) to be prepared, and the same directions may be followed for making *Oleum absinthii infusum, Oleum chamomillæ* (*matricariæ*) *infusum,* etc.

The National Formulary gives the following general formula for the preparation of infused oils, which is a modification of the P. G. directions and yields better results:

Take of the dry herb, in moderately coarse (No. 40) powder, 200 Gm.; alcohol, 130 Gm.; ammonia water (10 per cent.), 4 Gm.; lard oil, 500 Gm.; cotton-seed oil, 500 Gm. Moisten the powdered herb with a sufficient quantity of the alcohol and ammonia water, previously mixed, then pack it tightly in a stone or enamelled iron vessel of suitable capacity, pour on the remainder of the ammoniated alcohol, cover it well, and allow the mixture to macerate for 24 hours. Then add 120 Gm. of the mixed oils, digest with frequent agitation, during 12 hours, at a temperature between 50° and 60° C. (122° to 140° F.), transfer the mixture to a strainer, and express strongly. To the residue, returned to the vessel, add the remainder of the oils, digest and express in the same manner, and unite the expressed portions.—N. F.

This process is well adapted for all narcotic herbs, the object being to liberate the alkaloidal constituents, which are then taken up by the warm oil. Infused oils of this character are of a deep-green color, which, however, gradually fades upon exposure to light, hence they should be kept in dark bottles or in a dark place.

OLEA PINGUIA.—Fixed Oils.

Fats, Fatty oils, E.; *Huiles grasses, Huiles fixes,* Fr.; *Fette, Fette Oele,* G.

Fixed oils and fats, called fixed because they cannot be volatilized by heat at ordinary pressures without decomposition, are glycerides (excepting the waxes proper) of fatty acids, and obtained from the animal and vegetable kingdoms. As a class they are broadly characterized by being unctuous to the touch, imparting a non-volatile greasy stain to paper except in the case of crystalline fats, in being lighter than water, the specific gravity varying from 0.860 to 0.913–0.956, in being insoluble in water, and soluble in ether, chloroform, benzene, and carbon disulphide. According to their consistence at ordinary temperatures, 20° to 25° C. (68°–77° F.), they are known as *oils* (fixed oils proper)—liquid at ordinary temperatures; *fats* or *butters*—soft to quite firm;

tallows—firmer than fats; *waxes*—hard and more or less brittle. Their consistence is dependent upon the temperature, the liquid oils congealing to solid masses at suitably low temperatures, and the solid fats liquefying at high temperatures, both resuming their original consistence on restoration to the normal temperature.

Origin.—All plants, and perhaps all parts of plants, contain fat, though often in minute quantity. The liquid and solid fats are most likely generated from starch and other carbohydrates and allied compounds; De Luca (1862) proved that the fixed oil of olives increases in quantity as the mannite of the green olives disappears, and that access of air and light facilitates the conversion It is not unlikely that certain protein compounds may likewise be the source of fats. In the animal economy fats are, at least partly, produced in a similar manner, and to a considerable extent directly from the fats taken into the system with food.

Preparation.—From animal tissues rich in fat the latter is obtained by fusion either by itself or in the presence of water, and removal of the tissue by skimming or straining. Vegetable tissues containing notable quantities of fat yield it on being subjected to powerful pressure, either at the ordinary temperature or between plates which are heated slightly above the fusing-point of the fat; but since a certain quantity of the fat is mechanically retained by the tissues, a larger yield is had by the use of a solvent, such as carbon disulphide or petroleum benzin, which on being distilled off leaves the fat behind. When the bruised or cut vegetables are boiled with water, the fused fat rises to the surface, and may either be skimmed off or obtained by straining, expression, and subsequent separation from the water; such fats are usually inferior to those obtained from the dried article by pressure alone.

Purification.—The impurities contained in fats are protein and mucilaginous compounds derived from the vegetable tissue, and may be removed by means of felt or flannel filter-bags; the filtration is facilitated by a somewhat elevated temperature. On the large scale the purification is effected by the gradual addition to the oil of 0.5 to 2 per cent. of sulphuric acid, whereby the impurities are carbonized; the oil is then agitated with water to remove adhering acid, decanted, and often filtered through charcoal, or through tow, moss, or similar material, upward filtration being preferred. The use of sulphuric acid for the purification of oils was introduced into England by Gowen (1790). Chloride of zinc has a similar effect, according to R. Wagner, if used in concentrated solution, 1 to 1.5 per cent. being required; and Barreswill (1858) recommended for the same purpose the saponification of a small proportion of the fat by means of a weak solution of potassium or sodium hydroxide. From 1 to 2 per cent. of ammonia will often be effectual, and as mechanical agents for separating the impurities powdered clay, fullers' earth, and plaster-of-Paris have been found to serve a good purpose. The loss sustained in purification varies with the nature and amount of the impurities, and in some cases reaches 15 or 20 per cent. of the crude oil.

Bleaching.—The treatment of fats with sulphuric acid usually destroys also the coloring-matter wholly or in part; treatment with animal charcoal renders the fats lighter, and many are bleached (and often become rancid) by exposure to direct sunlight, a strip of lead being sometimes introduced into the fat if liquid, or this is occasionally agitated with an aqueous solution of ferrous sulphate. Palm oil is bleached by being rapidly heated to 240° C. (464° F.) and keeping it at this temperature for 10 minutes. The same effect is produced upon oil of poppyseed by heating it for 5 hours to between 90° and 95° C. (195° and 203° F.). Oxidation of the coloring principle by means of permanganic or chromic acid or hypochlorites has likewise been recommended.

Classification.—Fixed oils may be divided into drying and non-drying oils, the former upon exposure to air gradually thickening, and if in thin layers forming varnish-like masses, whereas non-drying oils remain fluid and become rancid. Drying oils may also be distinguished from non-drying oils by their behavior with sulphuric and nitrous acids. If 50 Gm. of a fixed oil be mixed with 10 Cc. of concentrated sulphuric acid, heat will be developed varying in intensity for different oils, the drying oils always showing the greatest rise in temperature. This is known as Maumené's test. Olive oil thus treated increases 42 degrees C. in temperature, castor oil 47 degrees C., almond oil 52 degrees C., cottonseed oil (crude) 69 degrees C.—(refined) 75 degrees C., hempseed oil 98 degrees C., and linseed oil 103 degrees C. When mixed with nitrous acid, non-drying oils are gradually converted into a solid mass, varying from soft to firm consistence, and known as elaïdin, while drying oils remain fluid even after prolonged contact, although a few become somewhat thicker. The test may be made by agitating

for a short time 1 part of copper foil with 5 parts each of nitric acid and the oil, and setting the mixture aside for about 6 hours, when solidification is generally completed.

The following classification of fixed oils and fats by Allen (*Commercial Organic Analysis*, 3d ed., 1899, vol. ii., Part I., p. 88) gives a general view of their more common properties and group relationships:

I. Olive Oil Group.—*Vegetable Oleins; Vegetable Non-drying Oils.*—Density 0.912 to 0.920. Their viscosity is notably greater than that of the drying oils. Exposure to air does not affect their power to produce a greasy stain on paper. These oils form very solid elaïdins, and embrace olive oil, almond oil, peach oil, apricot oil, earth-nut oil, and oil of ben.

II. Rape Oil Group.—The oils of this group, which includes rapeseed oil and the oils from black and white mustard seed, are all obtained from plants belonging to the family *Cruciferæ*. They are less perfectly non-drying oils than the members of the preceding group, slowly forming soft elaïdin, and have high iodine absorption-numbers and high saponification equivalents.

III. Cottonseed Oil Group.—Density, 0.920 to 0.930. These oils undergo more or less drying on exposure to air, and give little or no elaïdin on treatment with nitrous acid. In their general properties and in their behavior with sulphuric acid, bromine, and iodine, the oils of the cottonseed oil group occupy a position between the drying and non-drying oils. The group embraces cottonseed oil, cress-seed oil, sesamé or teel oil, sunflower oil, hazelnut oil, camelina oil, beech-nut oil, grapeseed oil, and maize oil.

IV. Linseed Oil Group.—*Vegetable Drying Oils.*—Density 0.923 to 0.937. The viscosity of these drying oils is lower than that of the preceding groups. The oils are not solidified on treatment with nitrous acid, evolve great heat with strong sulphuric acid, and combine with large proportions of bromine and iodine. The group includes linseed oil, hempseed oil, poppyseed oil, tobacco-seed oil, weld-seed oil, nigerseed oil, walnut oil, and Scotch firseed oil.

V. Castor Oil Group.—Density 0.937 to 0.970, and all very viscous. The group includes castor oil and croton oil, which are remarkable for their ready solubility in alcohol and glacial acetic acid, and their marked purgative properties.

VI. Palm Oil Group.—Solid vegetable fats not containing notable quantities of glycerides of lower fatty acids. Their melting-points and densities are somewhat variable and capable of permanent alteration The densities of the melted fats at 98°–99° C. (208.4°–210.2° F.) compared with water at 15.5° C. (60° F.) vary from 0.859 to 0.898. This group includes palm oil, cacao butter, nutmeg butter or mace butter, shea or galam butter, mahwah butter, and Chinese tallow.

VII. Cocoanut Oil Group.—Solid vegetable fats having high densities and low saponification equivalents. The members of subgroup A contain notable quantities of glycerides of the *volatile* fatty acids which distinguishes the oils from all other fats except fish oils and butter.

Subgroup A.—Includes cocoanut oil, palm-nut or palm-kernel oil, and laurel oil.

Subgroup B.—Glycerides of wax-like consistence. It includes Japan wax and myrtle wax.

VIII. Lard Oil Group.—*Animal Oleïns.*—This group includes those natural and manufactured oils, fluid at ordinary temperatures, which are obtained from terrestrial animals. They resemble the marine animal oils in their reaction with chlorine, but are not turned brown by boiling with caustic alkalies. They do not dry notably on exposure to air and give more or less solid elaïdin with nitrous acid. Density 0.914 to 0.916. The group includes neat's foot oil, bone oil, lard oil, and tallow oil.

IX. Tallow Group.—*Solid Animal Fats.*—Fats from terrestrial animals, solid or semisolid at ordinary temperatures. The group comprises tallow, suet, lard, horse fat, bone fat, wool fat (*suint*), oleomargarine, and butter fat. Butter fat (as well as the fat from the milk of all the mammalia) is distinguished from the other fats of this group by its high density, low saponification equivalent, and its content of a large percentage of butyric and other volatile fatty acids.

X. Whale Oil Group.—*Marine Animal Oils.*—Fluid oils obtained from fish and marine animals, and readily distinguished as a class by their offensive fishy odor, which becomes more perceptible on warming; by the reddish-brown color they assume when subjected to the action of chlorine; the reddish or reddish-brown color produced on boiling them with dilute solutions of caustic alkali. Concentrated sulphuric acid produces light-red to purple and brown coloration with considerable evolution of heat. Most of

these oils dry more or less on exposure to air, and yield but little elaïdin on treatment with nitrous acid. Density at 15° C. (59° F.) 0.911 to 0.933. The group comprises whale oil, porpoise oil, seal oil, menhaden oil, cod-liver oil, and shark-liver oil.

XI. SPERM OIL GROUP.—*Liquid Waxes.*—This group contains no glycerides (distinction from preceding groups), but consists of ethers of monatomic alcohols of the ethylic series, differing from the true waxes in being fluid at ordinary temperatures. They do not dry or thicken notably on exposure to air, but yield solid elaïdins on treatment with nitrous acid. Density at 15° C. (59° F.) 0.875 to 0.922. This group comprises sperm oil, Doegling oil, or bottlenose oil, and dolphin oil.

XII. SPERMACETI GROUP.—*Waxes Proper.*—The members of this group are solid at ordinary temperatures. They yield no glycerin on saponification, as they are compound ethers of the higher alcohol radicals of the ethylic series with in some cases an admixture of higher monatomic alcohols and higher fatty acids in the free state. The group includes spermaceti, beeswax, Pela or Chinese wax, opium wax, palm wax, and Carnauba or Brazil wax.

Properties and Composition.—Fats in a *pure* state *per se* are colorless, odorless, and tasteless. The color, odor, and taste common to many oils and fats are attributable to admixtures of more or less minute quantities of substances derived naturally from the seeds, etc., during the expression of the oil, the oil acting as a solvent of the coloring and other matter, and it is commercially impracticable to remove these entirely without destroying the oil. When oils and fats are heated to near 300° C. (572° F.) they undergo rapid decomposition, emitting among other gases extremely acrid and irritating vapors of *acrolein.* When heated to a red heat in a closed vessel without access of air, or passed through a tube under like conditions, oils undergo destructive distillation, breaking up into tarry matter and illuminating gases containing ethylene and acetylene. Fats are soluble in the usual volatile water-immiscible solvents. Castor and croton oil are soluble in alcohol, whereas other fats are but slightly soluble. Oils and fats are miscible with one another, and are good solvents of resins, camphor, and oleates. Both liquid and solid fats while in a pasty condition are separable by expression into a more liquid and a more solid fraction with a corresponding change in the melting-point of the same. With few exceptions natural fats and oils are mixtures of compound ethers or esters—glycerides—olein, myristin, palmitin, stearin, butyrin, etc., the liquid oils containing a preponderance of olein and the more solid fats a preponderance of palmitin and stearin, with admixtures of other glycerides in both instances. The glycerides are compound ethers of the triatomic alcohol—*glycerin*, $C_3H_5(OH)_3$, and the fatty acids combined with the same belong to two series of acids: the fatty acid group of the general formula $C_nH_{2n}O_2$—comprising butyric ($C_4H_8O_2$), valeric ($C_5H_{10}O_2$), caproic ($C_6H_{12}O_2$), caprylic ($C_8H_{16}O_2$), capric ($C_{10}H_{20}O_2$), lauric ($C_{12}H_{24}O_2$), myristic ($C_{14}H_{28}O_2$), palmitic ($C_{16}H_{32}O_2$), stearic ($C_{18}H_{36}O_2$), and arachidic ($C_{20}H_{40}O_2$) acids—the latter a component part of earth-nut and human fat; and the oleic acid group of the formula $C_nH_{2n-2}O_2$—and typified by oleic ($C_{18}H_{34}O_2$), erucic ($C_{22}H_{42}O_2$), and hypogæic ($C_{16}H_{30}O_2$) acids. Erucic acid is found in oil of mustard and hypogæic acid in ground-nut oil. All of these acids are monobasic. The neutral fats therefore contain 3 molecules of the acid to 1 of the triatomic radical—*glyceryl*—(C_3H_5), elucidated by the combination of *glycerin* with *stearic* acid to form *stearin:* $C_3H_5(OH)_3$ (glycerin) + $3HC_{18}H_{35}O_2$ (stearic acid) = $C_3H_5\begin{matrix}C_{18}H_{35}O_2\\C_{18}H_{35}O_2\\C_{18}H_{35}O_2\end{matrix}$ (stearin) + $3H_2O$. The compound with the fatty acids is conveniently named by changing the termination of the acid to *in;* thus stear*ic* acid to stear*in*, or tristearin, $C_3H_5(C_{18}H_{35}O_2)_3$, and ole*ic* acid to ole*in*, or triolein, $C_3H_5(C_{18}H_{33}O_2)_3$. The glycerides most prominently distributed as components of fats and oils are stearin, palmitin, myristin, laurin, caproin, and butyrin. The latter more particularly is found as a prominent constituent of milk fats and butter. There is evidence to support the theory that the glycerides in butter fat are of a compound nature—*i. e.*, that 2 or 3 fatty acids are combined with glyceryl in the same molecule. When heated with sulphuric acid, or superheated with water under pressure, or boiled with alkali hydroxides, the fats undergo saponification, splitting up into glycerin and fatty acids or a soap of the latter when alkali is used. Thus in the saponification of pure stearin the following reaction occurs: $C_3H_5(C_{18}H_{35}O_2)_3$ (stearin) + 3NaOH (sodium hydroxide) = $3NaC_{18}H_{35}O_2$ (sodium stearate) + $C_3H_5(OH)_3$ (glycerin).

OLEIN.—*Triolein. Elain.* $C_3H_5(C_{18}H_{33}O_2)_3$.—Olein cannot be obtained pure and

free from admixtures of palmitin and stearin by expression from fats or oils. It has been prepared by heating oleic acid with glycerin at 240° C. (464° F.). Olein is a clear colorless liquid having a specific gravity at 15° C. (59° F.) of 0.900. It is more readily soluble in ether, chloroform, and other solvents than palmitin or stearin. It may be distilled *in vacuo* without decomposition. Nitrous acid converts it into a pasty isomeric form—*elaïdin*, $C_3H_5(C_{18}H_{33}O_2)_3$, melting at 34° C. (93.2° F.), and which on saponification yields *elaïdic* acid ($C_{18}H_{34}O_2$), which in a purified state melts at 45° C. (113° F.), as against 14° C. (57.2° F.), the melting-point of its isomer oleic acid.

PALMITIN.—*Tripalmitin.* $C_3H_5(C_{16}H_{31}O_2)_3$.—Palmitin may be prepared synthetically by heating glycerin and palmitic acid and purifying the product by recrystallization from alcohol. It is obtainable in the form of white to pearl-white crystalline masses. It is less soluble in ether, chloroform, etc., than olein, and somewhat more soluble in the same solvents than stearin. In crystalline form it melts at 62°–64° C. (143.6°–147.2° F.) and congeals at 45.5° C. (114° F.). Its melting-point, like that of the other glycerides, is much affected by the manner in which it has been heated. Thus it may be made to melt at 47° C. (116.6° F.). With stearin it comprises the more solid portion of fats.

STEARIN.—*Tristearin.* $C_3H_5(C_{18}H_{35}O_2)_3$.—Stearin is obtained by heating a mixture of glycerin and stearic acid to about 275° C. (527° F.), and purifying the product by repeated crystallization from alcohol. It may be obtained by the purification of lard stearin by solution in ether and repeated recrystallization from ether to remove the palmitin. Stearin melts at 55°–71.6° C. (131°–161° F.). According to observations by Heintz, stearin when crystallized from ether melts at 71.6° C. (161° F.) and congeals to a crystalline mass at 70° C. (158° F.); but if heated to only 4 degrees C. above the melting-point it does not again congeal until about 52° C. (125.6° F.), forming a wax-like mass which will melt again at 55° C. (131° F.). Stearin is obtainable as a white to pearl-white crystalline powder. It is more difficultly soluble in the volatile solvents than the preceding glycerides.

BUTYRIN.—*Tributyrin.* $C_3H_5(C_4H_7O_2)_3$.—Butyrin is obtained on long-continued boiling of butyric acid and glycerin, or more rapidly by heating the mixture under pressure. It forms a butter-like substance having the specific gravity of 1.054 at 15° C. (59° F.), and may be distilled *in vacuo* without decomposition. It is soluble in ether, chloroform, and carbon disulphide. This glyceride is a constituent of all milk fats, which lends force to the theory that it performs some special function as a constituent of foods.

Preservation.—Fats should be kept in a dry place at a low temperature, and protected from light and air. On being exposed to the atmosphere the fats gradually become rancid, and this change is accelerated by the presence of animal and vegetable tissue, protein, and mucilaginous compounds; hence the importance of careful purification. The rancidity is due to the generation of odorous compounds and liberation of free fatty acids, besides some coloring-matter. Rancid fats may be improved, and to a certain extent restored, by washing with warm water or by treating them with magnesia or other weak alkali, and afterward washing them well. Treatment with strong alcohol or agitation of the oil with a little powdered borax and exsiccated sodium carbonate has likewise been recommended.

Adulterations.—The higher priced oils are not infrequently adulterated with cheaper ones, and occasionally with resin and mineral oils. Mixtures of animal and vegetable oils are generally difficult to detect owing to similarity in composition. Moreover, the physical and chemical characteristics of oils are to a considerable extent modified by various processes of refining and keeping, especially where the oils are exposed to the influence of light and air. Admixtures are detected by determining the physical and chemical properties and comparing same with oils of known purity. Adulteration by mineral and resin oils is detected by the character of the unsaponifiable matter extractable from the dried soap of the saponified oil. The color, taste, odor, consistence, viscosity, specific gravity, melting- and congealing-point of the oils, as well as of the fatty acids from the same, give valuable data which supplemented with chemical tests serve to identify the adulterations. The color reactions with concentrated sulphuric acid, nitric acid, mixtures of sulphuric and nitric acids, as well as the elaïdin test, should be made under fixed uniform conditions. Very useful data are obtained by determining the

Saponification value (Koettstorfer number)—the number of milligrammes of potassium hydroxide required for the complete saponification of 1 Gm. of fat.

The U. S. P. gives the following directions for ascertaining the saponification value of

fats and oils: Weigh out accurately in a flask holding 150 to 200 Cc. (1.5–2 Gm.) of the purified and filtered fat. Next run into the flask with a pipette, 25 Cc. of alcoholic potassium hydroxide test-solution. While exactly 25 Cc. is not indispensable, in comparative tests precisely the same amount must be used, allowing the pipette to drain in exactly the same way in each test. Then place a small funnel in the flask and heat it on a water-bath containing boiling water for ½ hour, so that the alcohol is simmering, frequently imparting a rotatory motion to the contents of the flask. Then add 1 Cc. of phenolphthalein test-solution and titrate back the excess of potassium hydroxide with half-normal hydrochloric acid. If a blank test is made at the same time with the alcoholic potassium hydroxide test-solution alone, the difference in the number of Cc. of half-normal hydrochloric acid consumed by the blank test and the real test, multiplied by 27.87, and divided by the weight in grammes of the fat or oil, will give the saponification equivalent of the sample tested.

Reichert (or Reichert-Meissl) *value*—the number of Cc. of tenth-normal alkali hydroxide solution required to neutralize the fractional distillate from 2.5 (or 5 in Reichert-Meissl) Gm. of fat under the conditions of the Reichert process. (See Allen's *Com. Org. Analysis*, 3d edit., 1899, vol. ii.). Excellent in the examination of butters.

Hübl or *iodine value*—the number of grammes of iodine absorbed by 100 Gm. of fat.

Hübl's process is based upon the saturation of unsaturated fatty acids and their glycerides by iodine in the presence of an alcoholic solution of mercuric chloride. The solutions required are: 1. *Solution of iodine* and *mercuric chloride.* Dissolve separately 25 Gm. of iodine and 30 Gm. of mercuric chloride, each in 500 Cc. of 95 per cent. alcohol and mix the clear solutions, and let the mixture stand 12 hours before use. 2. *Solution of sodium thiosulphate:* 24.8 Gm. of the crystallized salt in distilled water diluted to 1000 Cc. Tenth-normal solution of iodine = 0.01259 Gm. of iodine per Cc. 3. A 10 per cent. *solution* of *potassium iodide* in water. 4. *Starch solution* (a fresh solution of starch in water). 5. *Pure chloroform.*

Of the fats to be examined, take 0.15–0.18 Gm. of a drying or fish oil, 0.30–0.40 Gm. of a non-drying oil, and 0.80–1 Gm. of a solid fat. Dissolve the oil in a 500 Cc. stoppered flask in 10 Cc. of chloroform, add 25 to 30 Cc. of the iodine (1) solution, and shake the mixture. If it is not clear, add more chloroform; and if it decolorizes inside of 2 hours, add more of the iodine solution. At the end of 4 hours the solution may be titrated. Add about 20 Cc. of the potassium iodide (3) solution, shake the mixture, dilute it with about 300 Cc. of water, and, using the starch solution as an indicator, titrate the excess of iodine with the thiosulphate (2) solution.

Elaïdin test (Poutet, 1819) is conveniently applied by means of the following reagent: Dissolve 18 Gm. of mercury in 15.6 Cc. of nitric acid, specific gravity 1.42, keeping the solution cool. Of this solution, add 1 Cc. to 25 Cc. of the oil to be tested, shake the mixture, and repeat the shaking several times at 10 minute intervals, and then set it aside for 12 or more hours for observation. The following table arranged by Allen shows the effect of the reagent upon the more common oils: (*a*) *A solid, hard mass* is yielded by olive, almond, arachis, lard, sperm, and sometimes neat's foot oil. (*b*) *A butter-like mass* is yielded by neat's foot, bottlenose, mustard, and sometimes by arachis, sperm, and rape oils. (*c*) *A pasty or buttery mass which separates from a fluid portion* is yielded by rape, sesame, cottonseed, sunflower, niger-seed, codliver, seal, whale, and porpoise oils. (*d*) *Liquid products* result from linseed, hempseed, walnut, and other drying oils.

In the subjoined table are given the *saponification* (Koettstorfer) *value* (*A*), the *Hübl* or *iodine value* of the oils (*B*), as well as that of the fatty acids (*C*) from the same, the *melting-points*[1] (*D*) and the *congealing-points* (*E*) of the fatty acids, and the effect of nitric acid upon some of the commonly occurring oils. Under (*F*), (*G*), and (*H*) are given the reactions observed by Bach (1883) upon agitating equal volumes (5 Cc.) of oil and nitric acid for 1 minute (*F*), after placing the mixture in boiling water for 5 minutes (*G*), and finally after having been set aside for about 18 hours at 15° C. (59° F.):

	(*A*)	(*B*)	(*C*)	(*D*)	(*E*)	(*F*)	(*G*)	(*H*)
Olive oil	185–196	79.5–91.5	86–90.2	24–26.5°	20–22°	pale-green	orange-yellow	solid
Cottonseed	191–210	102–111	111–115	32–38	27–34	yellow-brown	reddish-brown	butyraceous
Sesame	187–193	103–112	109–112	24–26.5	21–23	white	brown-yellow	liquid
Earth-nut	190–197	85.6–101	95.5–103	27–34	24–38	pale-rose	"	solid
Rapeseed	170–179	97–105.6	96–105	16–20	12–18	"	orange-yellow	"
Castor	176–186	83.4–85.9	866–859	13	2	"	golden-yellow	butyraceous
Sunflower	188–194	120–133	125–134	17–24	17–18	dingy-white	reddish-yellow	"

[1] Degrees C.

In the manufacture of oils from seeds valuable by-products result. The principal one of these—*oil-cake*—is used as a fodder and as an adjunct to fertilizers. About one-fourth of the amount produced is used in this country, and the remainder exported.

The imports and exports of the principal fixed oils, fats, oil-cake, oil-cake meal, oil seeds, etc., entering into the commerce of the United States for the fiscal year ending June 30, 1902 (Treasury Reports Commerce and Navigation of the United States, Vol. I.) are exhibited in the following table:

Imports.		*Value.*
Codliver oil (gallons)	218,080	$112,458
Castor oil (gallons)	3,993	3,227
"Alizarin assistant" (sulpho-ricinoleic acid) (gallons)	31,587	15,544
Almond oil (gallons)	120,634	21,418
Cocoanut oil (pounds)	28,068,927	1,679,034
Cacao butter "	3,548,041	782,815
Croton oil "	1,135	565
Linseed oil (gallons)	37,779	21,651
Hempseed and rapeseed (gallons)	775,963	346,312
Mace oil (pounds)	582	304
Other nut oils (gallons)	405,021	177,145
Olive oil, for manufacturing purposes (gallons)	2,509,192	976,429
Olive oil, in bottles, jars, etc. (gallons)	1,140,042	1,454,856
Olive oil, other grades (gallons)	194,680	152,227
Palm oil (pounds)	16,922,090	888,674
Sesame oil (gallons)	707,760	57,359
Castor beans (bushels)	312,323	356,901

Exports.		*Value.*
Corn oil (gallons)	4,266,394	$1,769,370
Cottonseed oil (gallons)	33,042,848	12,992,393
Linseed oil (gallons)	102,113	68,617
Lard oil (gallons)	460,035	327,794
Lard (pounds)	556,840,222	52,375,864
Oleo oil (pounds)	138,546,088	12,254,969
Oleomargarine[1] (pounds)	5,721,254	601,521
Lard compounds, cottolene, etc. (pounds)	36,201,744	2,687,653
Butter[1] (pounds)	16,002,169	2,885,609
Cottonseed (pounds)	56,403,344	509,627
Flaxseed (bushels)	3,874,033	6,031,887
Corn oil-cake and oil-cake meal (pounds)	14,740,498	164,056
Cottonseed oil-cake and oil-cake meal (pounds)	1,050,466,246	12,271,009
Flaxseed oil-cake and oil-cake meal (pounds)	582,886,875	7,508,133

OLEA VOLATILIA—Volatile Oils.

Olea ætherea; Olea destillata; Ætherolea.—Ethereal oils, Essential oils, Distilled oils, E.; *Huiles volatiles, Huiles éthérées, Huiles essentielles, Huiles distillées, Essences*, Fr.; *Flüchtige Oele, Aetherische Oele*, G.

Volatile oils are mixtures of those substances to which, in the majority of cases, the odors of plants are due. Although the attribute volatile is indicative merely of a physical property which most of these substances have in common, and in nowise refers to their source, the designation volatile oil has been restricted entirely to volatile oily products from the vegetable kingdom. In recent years it has been made to include artificial substances identical with or at least closely related to such natural plant products, as, for instance, oil of bitter almond when applied to synthetic benzaldehyde, or oil of wintergreen when applied to synthetic methyl salicylate.

The volatile oils are to-day obtained almost entirely by a process of distillation. For several centuries every imaginable drug was distilled with water in the preparation of aromatic waters. These preparations were supposed to contain the essential constituents of the drugs. Hence, when the distillers of these waters learned to obtain the volatile oils first as a by-product in the preparation of aromatic waters and later as the principal product in the process of distillation of plant drugs with water, these oils were designated essential oils. The word essence is defined as the quality or qualities

[1] Average about 85 per cent. of fat.

on which an object depends for being what it is. Consequently these essential oils were also designated essences, a term commonly employed by the French. The Germans appear to restrict the term essence to those essential oils which are not obtained by distillation, but by expression, viz., the essential oils of the citrus fruits: lemon, orange, and bergamot. In the English language the term essence is commonly used to designate alcoholic solutions of those constituents of a plant that compose the essential oil—*e. g.*, essence of lemon, essence of peppermint. With the development of the volatile oil industry these essences were made less and less from the plant parts by extraction with alcohol, but more and more by simple solution of the essential oil in strong alcohol. With the increasing knowledge of the chemistry of these oils it has been found that the principal bearers of the aroma of a volatile oil sometimes constitute but a small percentage of such an oil and are more readily soluble in dilute alcohol than the entire oil. Preparations containing these more soluble bearers of the aroma of a plant are designated soluble essences, the attribute soluble applying to solution in water. Thus while "The . . . . word *essence* . . . . scarcely underwent a more complete transformation when from being the abstract of the verb 'to be,' it came to denote something sufficiently concrete to be inclosed in a glass bottle," it had to submit to a second violent change of meaning in the newly coined phrase *water-soluble* essences, whereas the term essence when used synonymously with oil implies something that is not soluble in water.

Inasmuch as the aromatic waters were regarded as containing the more spirit-like products of the plant separated from the grosser particles, it was but logical to designate the oils obtained by water distillation ethereal oils, the German equivalent of which, "Aetherische Oele," is used by the Germans much more than the German equivalents of volatile oils ("Flüchtige Öele") commonly used in America or of essential oils ("Wesentliche Oele") the term preferred in England.

The Latin designation commonly used is *Olea ætherea* in Anglo-Saxon countries and *Essentia* in Romanic countries (*e. g.*, French Codex), the terms *olea volatilia* and *olea essentialia* being used as synonyms. In order to separate the volatile oils from the fatty oils in works of an encyclopædic character the three Scandinavian pharmacopœias have adopted the term *Ætherolea.*

Certain semi-artificial products somewhat resembling the volatile oils have commonly been classified with them—*e. g.*, oil of cade, oil of tar, etc. Inasmuch as they are obtained by a process of destructive distillation, the term *Pyrolea* has been suggested for them. The volatile oil *par excellence* of the U. S. P., 1890, the *Oleum Æthereum*, has never been classed with the volatile oils by any authority on this subject.

As will be seen, the term volatile oil defies definition, although interested persons commonly understand each other when using it. Nevertheless, numerous attempts have been made not only to define the term, but even to classify chemically these products, thus designated by common consent and for want of a better word. In the early decades of the nineteenth century, when elementary organic analysis was being applied to the study of volatile oils, it was found that some consisted almost altogether of carbon and hydrogen, others contained oxygen in addition to these two elements, and a third class contained sulphur and nitrogen as well. Ignoring altogether small percentages of oxygen in many oils, a classification into (1) hydrocarbon oils, (2) oxygenated oils, and (3) sulphur-containing oils was suggested. Strange to say, this classification is still in use in many text-books at the present time when manufacturers reject 90 per cent. of lemon oil, a typical hydrocarbon oil of the above classification, in order to get the valuable 10 per cent. rich in oxygenated constituents.

A rational classification based on chemical constituents or physical properties being out of the question, the best method of classifying the oils is according to the botanical classification of the plants from which they are obtained. Such a classification at least occasionally brings out genetic relationships. The following table of volatile oils is therefore arranged in accordance with Engler and Prantl's system. For further information special works should be consulted. The three latest and best reference works are herewith given in the order of their publication: 1899, Gildemeister und Hoffmann, *Die aetherischen Oele*, which has been translated into English and French; 1899, Parry, *The Chemistry of Essential Oils and Artificial Perfumes;* 1900, Charabot, Dupont et Pilet, *Les huiles essentielles.*

	Sp. gr.	(α)D	Constituents.	Remarks.
Order **Pinaceæ**.				
Pinus.				
P. palustris Mill.	0.8612	+23.93°	Pinene.	These 4 species constitute the largest pine forests of the Southern States and are the principal ones used in the production of American turpentine oil. See *Oleum Terebinthinæ.*
P. glabra Walt.	. . . . .	—31.5°	Pinene.	
P. Cubensis Gries.	0.8650	+9.6°	Pinene.	
P. echinata Mill.	. . . . .	. . . . .	Pinene.	
P. tæda L.	. . . . .	. . . . .	Pinene.	
P. pinaster Sol.	0.859–0.872	—20° to —40°	Pinene.	From this species French turpentine oil is obtained. It resembles American turpentine oil closely, but is lævogyrate.
P. Laricio Poiret.	0.866	+3°46′	Pinene (?).	The so-called Austrian turpentine oil is obtained from this species. It has but local commercial significance.
P. Khasya Royle.	0.8627	+36°28′	Pinene.	Two species from Burma which, according to Armstrong, might supply India with turpentine oil if the industry were developed.
P. Merkusii Jung.	0.8610	+31°45′	Pinene.	
P. Sabiniana Dougl.	0.694	. . . . .	*n*-Heptane.	This was sold in the San Francisco market under the names of aurantine, abietene, erasine, and theoline as a substitute for petroleum benzin for the removal of stains.
P. sylvestris L.				
Wood.	. . . . .	. . . . .	Pinene, sylvestrene, dipentene.	This "Kienöl" is not a volatile oil proper, but, like oil of cade, a product of destructive distillation. It belongs to the class of *Pyrolea* of the Scandinavian pharmacopœias, but is used as a substitute for turpentine oil, which it resembles.
German.	0.865–0.870	+18° to 22°	Pinene, sylvestrene, dipentene.	
Russian.	0.862–0.872	+15° to 24°	Pinene, sylvestrene, dipentene.	
Swedish.	0.871	+14°48′	Pinene, sylvestrene.	
Finland.	. . . . .	. . . . .	Pinene, sylvestrene, dipentene.	
Needles.				
German.	0.884–0.886	+7° to 10°	Bornyl acetate (3.5 per cent.), pinene, sylvestrene, dipentene, cadinene.	"Kiefernadelöl," not a commercial article.
Swedish.	0.872	+10°40′	Bornyl acetate(?) (3.5 per cent.), pinene, sylvestrene.	Swedish "Fichtennadelöl" finds application as inhalant in affections of the lungs, as admixture to baths, and in sprays for sick chambers.
English.	0.885–0.889	—7° to —19°	Bornyl acetate (?) (2.9 to 3.5 per cent.), pinene, sylvestrene(?), dipentene(?).	
P. Pumilio Haenke.				
Needles.	0.863–0.875	—4° to —9°	Bornyl acetate (5 to 7 per cent.), pinene, sylvestrene, cadinene, phellandrene	"Latschenkieferöl" or "Krummholzöl" distilled in Austrian Alps, etc.
P. cembra L.				
Needles.	. . . . .	+29.1°	Pinene.	
Galican turpentine.	0.863	+17°18′	Pinene.	Of unknown origin.
Larix.				
L. Larix (L.) Karst.				
Wood.	0.878	—11°	Pinene.	This constitutes about 15 per cent. of the Venice turpentine.
Leaves.	0.878	+0°22′	Bornyl acetate (about 8 per cent.) (?), pinene(?).	
L. Siberica Ledeb.	. . . . .	. . . . .	Bornyl acetate, pinene, terpineol.	
Abies.				
A. Sibirica Ledeb.	. . . . .	. . . . .	Camphene.	A Russian oil.
A. balsamea (L.) Mill.				
Balsam.	. . . . .	. . . . .	Pinene.	Canada balsam yields about 16 to 24 per cent. of this oil. Comp. *Terebinthina Canadensis.*

	Sp. gr.	$(\alpha)_D$	Constituents.	Remarks.
Order **Pinaceæ.**				
A. balsamea (L.) Mill.				
Needles.	0.888	—28.9°	Pinene, bornyl acetate (17.6 per cent.).	
A. Fraseri (Pursh.) Lindl.				
Balsam.	. . . . .	. . . . .	Pinene.	Comp. *Terebinthina Canadensis.*
A. Picea (L.) Lyons.				
Balsam.	0.861	. . . . .	Pinene.	Comp. Strassburg turpentine.
Needles.	0.869–0.875	—20° to —59°	Bornyl acetate (5 to 10 per cent.), pinene, terpineol, sesquiterpene.	This is one of the pine-needle oils, "Fichtennadelöl," used in sprays: "Edeltannennadelöl.
Cones.	0.853–0.870	—60° to —76°	Bornyl acetate (0.5 to 4 per cent.) (?), pinene, limonene.	The "Templinöl" or "Edeltannenzapfenöl" distilled in Switzerland.
A. cephalonica Link.				
Cones.	0.868	—20°	Pinene (?), dipentene(?), limonene(?).	
A. Abies (L.) Rusby.				
Wood.	0.866	+3°5′	Pinene.	
Needles.	0.880–0.888	—21° to —37°	Bornyl acetate (8 to 10 per cent.), pinene, dipentene, phellandrene, cadinene.	"Fichtennadelöl" proper distilled from the fresh needles and twigs of the Norway spruce.
Picea				
P. Canadensis (Mill.) B. S. P.				
Needles.	0.9288	—18.4°	Bornyl acetate (about 52 per cent.), pinene.	
Balsam.	. . . . .	. . . . .	. . . . .	Comp. *Terebinthina Canadensis.*
P. Mariana (Mill.) B. S. P.				
Needles.	0.922	—36.3°	Bornyl acetate (about 50 per cent.), pinene (?).	
Cedrus.				
C. Libani Barr.	0.985	—10°48′		
Sequoia.				
S. gigantea Torr.				
Needles.	0.8522	. . . . .	Pinene(?), sesquojene.	
Callitris.				
C. quadrivalvis Vent.	. . . . .	. . . . .	. . . . .	About 1 per cent. of oil has been obtained from sandarac resin.
Thuja.				
T. occidentalis L.				
Needles.	0.915–0.935	—5° to —14°	Pinene, fenchone, thujone, dihydrocarvone (?).	
T. orientalis L.				
Root.	0.979	. . . . .	Thymoquinone (?).	
Cupressus.				
C. sempervirens L.	0.88–0.89	+4° to 14°	Pinene, sylvestrene(?), cedrol (?), sesquiterpenes (?).	Cypress oil has been recommended for whooping-cough.
Chamæcyparis.				
C. obtusa Endl.				
Leaves.	. . . .	. . . . .	. . . . .	A Japanese oil resembling savin oil.
Juniperus.				
J. communis L.				
Berries.	0.865–0.882	up to —11°	Pinene, cadinene, juniper camphor.	See *Oleum Juniperi.*
J. Phœnicea L.				
Berries.	0.859	—4°55′	. . . . .	A Smyrna oil resembling juniper oil.
J. Oxycedrus L.				
Berries.	0.851–0.854	—4° to —8°	. . . . .	This oil has a terebinthinate odor, resembling faintly that of juniper.
J. Sabina L.				
Leaves.	0.910–0.930	+42° to 60°		See *Oleum Sabinæ.*

	Sp. gr.	$(\alpha)_D$	Constituents.	Remarks.
Order **Pinaceæ.**				
Juniperus Virginiana L.				
Wood.	0.945–0.960	—30° to —40°	Cedrene, cedrol.	Virginia or red cedar oil is used in perfumery. The oil obtained as a by-product in drying the wood for lead-pencils is inferior.
Leaves.	0.887	+59°25′	Borneol, cadinene, limonene, bornyl valerianate (?).	Cedar leaf oil of commerce is not always distilled from this plant. See *T. occidentalis.*
Order **Liliaceæ.**				
Aloe.				
A. vera (L.) Webb.	0.863			
Xanthorrhœa.				
X. hastile R. Br.	0.937	—3°14′	Styrene, cinnamic acid.	
Allium.				
A. sativum L.	1.046–1.057	. . . . .	Allyl propyl disulphide, allyl disulphide, $C_6H_{10}S_3$, $C_6H_{10}S_4$.	
A. cepa L.	1.036	—5°	$C_6H_{12}S_2$.	
A. ursinum L.	1.015	. . . . .	Vinyl sulphide, vinyl polysulphides, mercaptan, and an aldehyde.	
Asagraea.				
A. officinalis (Ch. et Sch.) Lindl.	0.902–0.928	. . . . .	Methyl and ethyl esters of oxymyristic and veratric acids, aliphatic aldehyde.	
Order **Iridaceæ.**				
Crocus.				
C. sativus L.	. . . . .	. . . . .	Terpene.	
Iris.				
I. florentina L. *I. germanica* L. *I. pallida* L.	. . . . .	. . . . .	Myristinic acid (85 per cent.) and methyl ester, irone, oleic acid and esters, olcic aldehyde.	Myristic acid is odorless. The violet odor is due to the traces of irone.
Order **Zingiberaceæ.**				
Curcuma.				
C. longa L.	0.942	. . . . .	Phellandrene, turmerol, valerianic and capronic acids.	
C. zedoariæ Rosc.	0.990–1.01	. . . . .	Cineol, sesquiterpene (?).

Paracota bark.	0.9275	. . . . .	Terpenes, cadinene, methyl eugenol, sesquiterpene hydrate?	
Cinnamomum.				
C. camphora N. et E.	. . . . .	. . . . .	Acetaldehyde, pinene, phellandrene, cineol, dipentene, camphor, terpineol, safrol, eugenol, cadinene.	Normal camphor oil is a semisolid mass, or a liquid mixed with camphor. The camphor oil of commerce is a product from which much camphor has been removed. "White camphor oil" consists of the lowest boiling fractions and contains terpenes almost exclusively, also some cineol. Specific gravity up to 0.890. "Black camphor oil" is that portion which boils higher than camphor and contains safrol, eugenol, and sesquiterpenes. Sp. gr. from 0.900 to over 1.000.

	Sp. gr.	(α)D	Constituents.	Remarks.
Order **Lauraceæ.**				
Cinnamomum.				
C. Zeylanicum Breyne.				
Bark.	1.024–1.040	up to —1°	Phellandrene, eugenol, cinnamic aldehyde (65 to 75 per cent.), etc.	In the bark oil cinnamic aldehyde predominates, though its characteristic odor is due to esters, etc.; in the leaf oil, eugenol; in the root oil, camphor.
Leaves.	1.044–1.065	—0°5′ to +1°18′	Safrol, eugenol, cinnamic aldehyde, terpenes, benzaldehyde (?).	Commercial oil of Ceylon cinnamon mostly consists of leaf oil with some of the bark oil. It is used in preference to cassia oil where a finer cinnamon odor is desired.
Root.	. . . . .	. . . . .	Camphor, cinnamic aldehyde.	
C. Cassia Bl.	. . . . .	. . . . .	Cinnamic aldehyde.	See *Oil of Cinnamon.*
C. Loureirii Nees.	0.982	. . . . .	Cinnamic aldehyde, terpene (?).	Japanese cinnamon oil.
C. Kiamis Nees.	. . . . .	. . . . .	Massoy camphor.	Massoy bark oil.
C. Culilawan Bl.	. . . . .	. . . . .	Terpineol, eugenol.	
C. Wightii Meissn.	. . . . .	. . . . .	Methyl eugenol.	
C. Oliveri.	. . . . .	. . . . .	Cineol, safrol (?), eugenol (?), cinnamic aldehyde (?).	The tree is known in Australia as black, brown, or white sassafras.
Persea.				
P. Persea (L.) Cockerell.	0.9607	. . . . .	Methyl chavicol (?).	
P. caryophyllata Mart.	. . . . .	. . . . .	Eugenol (?).

Pelargonium.				
P. odoratissimum Willd. *P. capitatum* Ait. *P. Radula* (Cav.) Ait.	0.89–0.906	—6° to —16°	Geraniol, geranyl tiglate, citronellol, menthone, acetic, isobutyric, and isovalerianic acids, paraffin.	Oil of rose geranium. The French, Algerian, Réunion, Spanish, and German oils show slight variations.

	Sp. gr.	$(\alpha)_D$	Constituents,	Remarks.
Order **Tropæolaceæ.**				
Tropæolum.				
T. majus L.			Benzyl mustard oil.	Oil of garden nasturtium will vary according to the treatment of the glucoside yielding it. Heat splits off benzyl cyanide, whereas a ferment hydrolizes it to benzyl-isosulphocyanate.
Order **Erythroxylaceæ.**				
Erythroxylon.				
E. Coca Lam.			Methyl salicylate, acetone, methyl alcohol.	Coca leaves contain but traces of oil.
Order **Zygophyllaceæ.**				
Bulnesia.				
B. Sarmienti Lor.	0.965–0.975	—6° to —7°	Sesquiterpene hydrate.	Guaiac wood oil is used in perfumery to produce a tea-rose odor, also as an adulterant of oil of rose. The odoriferous constituents of the oil are not known.
Order **Rutaceæ.**				
Xanthoxylum.				
X. piperitum DC.	0.973		Terpene, crystalline body $C_{10}H_6O_4$, citral.	Japanese oil of pepper.
Fagara.				
F. Hamiltonianum (Wall.) Engl.	0.840			
Ruta.				
R. graveolens L.	0.833–0.840	+0°13′ to +2°10′	Methyl nonyl ketone, methyl heptyl ketone, lauric aldehyde(?).	Whereas in Spanish oil of rue methyl nonyl ketone predominates, in the Algerian oil the methyl heptyl ketone predominates.
Boronia.				
B. polygalifolia Sm.	0.839	+10°		
Barosma.				
B. betulina (Thunb.) Bart. et Wend.				Buchu oil.
B. serratifolia (Curt.) Willd.			Diosphenol, hydrocarbon $C_{10}H_{18}$, menthone (?).	
B. crenulata (L.) Hook.				
Empleurum.				
E. serrulatum Soland.			Methyl nonyl ketone (?).	
Pilocarpus.				
P. Jaborandi Holmes.	0.865–0.895	+3°25′	Dipentene (?), methyl nonyl ketone.	
Cusparia.				
C. Angustura (Rich.) Lyons.	0.93–0.96	—36° to —50°	Pinene (?), sesquiterpene alcohol, cadinene, galipene.	Angostura bark oil.
Toddalia.				
T. aculeata Pers.			Citronellal.	This Indian oil would be useful in perfumery if it could be furnished at a reasonable price.
Citrus.				
C. Limonium Risso.				
Rind.				See *Lemon Oil.*
Leaves, twigs, and unripe fruit.	0.868–0.874	+22° to 34°	Citral.	Petitgrain citronnier. Comp. oil of petitgrain (sweet).
C. Aurantium L.				
Rind.				See *Oil of Orange.*
Flowers.				Oil of sweet orange blossoms of commerce appears to be a mixture of different aurantiaceous oils.
C. amara (L.) Lyons.				
Rind.				Oil of bitter orange. Comp. oil of orange.
Leaves.	0.8910–0.8934	—5° to —6°	50 to 70 per cent. ester.	
Immature fruits, leaves, and twigs.	0.887–0.900	—1° to +3°	Limonene, geraniol, geranyl acetate, linalool, linalyl acetate, sesquiterpene.	Oil of petitgrain.

	Sp. gr.	$(\alpha)_D$	Constituents.	Remarks.
Order **Rutaceæ.**				
Citrus.				
C. amara (L.) Lyons.				
Flowers.	0.870–0.890	+0° to +5°	Limonene, linalool, geraniol, linalyl acetate, anthranilic acid methyl ester, paraffin.	Oil of bitter orange flowers, or neroli oil, is obtained principally as a by-product in the manufacture of orange-flower water (see *Aqua aurantii floris*), but should not be used in making an orange-flower water, since it contains less methyl anthranylate than the oil dissolved in the water. It was officinal in the U. S. P. of 1880 and 1890, and is still officinal in several Romanic countries and Austria. The oil is used in perfumery.
C. Bergamia Risso.	0.882–0.886	+8° to +20°	Limonene, linalool, linalyl acetate (30–40 per cent.), bergapten, bergaptin.	Bergamot oil is used in perfumery. It is valued according to its linalyl acetate content. According to the U. S. P., 1890, in which it was official, it should be soluble in one-half its volume of alcohol, and not become turbid upon the addition of more alcohol. Upon evaporation on a water-bath it should not leave a residue of more than 6 per cent.
C. medica L.	0.871	+67°8′	Citral.	Commercial cedro oil is reported to be a mixture of lemon oil with other oils.
C. madurensis L.	0.854–0.858	+65° to 75°	Citral, citronellal(?), limonene.	Mandarin oil somewhat resembles lemon oil.
C. acida Pers.				
a. Expressed.	0.873–0.882	+35° to 38°	Citral.	The expressed West Indian limette oil closely resembles oil of lemon, whereas the distilled oil has a terebinthinate odor.
b. Distilled.	0.865–0.868	+38°52′		
C. Limetta Risso.				
Rind.	0.872	+58°19′	Limonene, linalyl-acetate, linalool, limettin.	Italian limette oil resembles bergamot oil, but contains less ester (26 per cent.) and more limonene.
Leaves.	. . . . .	. . . . .	Limonene, methyl-nonyl ketone(?).	
C. Decumana Murr.	0.860	+94°30′	. . . . .	Shaddock or grape-fruit oil.
"*C. oleifera.*"	0.870–0.880	1° to 5°		
Order **Burseraceæ.**				
Commiphora.				
C. Myrrha (Nees) Engl.	0.988–1.007	—67° to 90°	. . . . .	Herabol myrrh oil.
C. species.	0.8836	—14°20′	Terpene.	Bisabol myrrh oil.
C. Kataf Eng.	0.870–0.905	—10° to 12°	. . . . .	The present opoponax oil of commerce, not the oil from true opoponax.
Boswellia.				
B. Carterii Birdw.	0.875–0.885	—10° to 17°	Pinene, dipentene, phellandrene.	Oil of olibanum or frankincense.
Canarium.				
C. species.	0.87–0.91	+44°3′	Dipentene, phellandrene, polyterpene.	Elemi oil.
Protium.				
P. heptaphyllum.	. . . . .	. . . . .	Conimeme.	Oil of conima resin or Hyawa gum.
Bursera. *B. aloexylon* Eng. *B. Delpechiana* Poiss.	0.875–0.880	—5° to —12°	Linalool, geraniol, methyl heptenone, sesquiterpene, terpene.	Mexican linaloe oil. This is the linaloe oil of commerce, which is used extensively in perfumery.

	Sp. gr.	$(\alpha)_D$	Constituents.	Remarks.
Order **Meliaceæ.**				
Cedrela.				
C. species.				
From Corinto.	0.906	—17°23′	. . . . .	About twelve species of this genus, indigenous to America, yield a pleasantly odoriferous wood, which is used for making cigar and sugar boxes. It is incorrectly called cedar wood. Volatile oils have been distilled from a number of these woods, the botanical sources of which are unknown.
From Cuba.	0.923	+18°6′	Cadinene.	
From La Plata.	0.928	. . . . .	. . . . .	
From Punta Arenas.	0.915	—5°53′	Cadinene.	
From Porto Alegre.	0.9348	—0°22′	. . . . .

Order **Turneraceæ.**				
Turnera.				
T. aphrodisiaca Ward. / *T. diffusa* Ward.	. . . . .	. . . . .	. . . . .	Various plants have supplied the damiana leaves of commerce, hence nothing definite about this oil is known.
Order **Lythraceæ.**				
Lawsonia.				
L. inermis L.	. . . . .	. . . . .	. . . . .	Henna oil is said to resemble that of the tea rose.
Order **Myrtaceæ.**				
Myrtus.				
M. communis L.	0.890–0.915	+10° to 30°	Cineol, pinene, dipentene, linalool (?).	Oil of myrtle was formerly much used in the preparation of myrtol, fraction 160°–180° of the oil, which evidently consisted largely of cineol (eucalyptol), to which the antizymotic and deodorizing properties of the preparation were, no doubt, largely due.
M. Cheken Spr.	0.8795	. . . . .	Cineol, pinene.	Oil of cheken leaves.
Pimenta.				
P. Pimenta (L.) Lyons.				
Unripe berries.	. . . . .	. . . . .	. . . . .	See *Oil of Allspice.*
P. species.				
Leaves.	0.882	—0°37′	Citral.	Oil of Trinidad pimenta leaves.
P. acris (Swz.) Wight.	. . . . .	. . . . .	. . . . .	See *Oil of Bay.*
Eugenia.				
E. aromatica (L.) Kuntze.				
Fruit.	. . . . .	. . . . .	. . . . .	See *Oil of Cloves.*
Stems.	1.040–1.065	up to —1°10′	Eugenol, caryophyllene, methyl alcohol, furfurol, methyl amyl ketone (?).	Oil of clove stems, though richer in eugenol than oil of cloves, is less fine in flavor and should, therefore, not be used in perfumery and pharmacy. Comp. oil of cloves.
Cajuputi.				
C. viridiflora (Gærtn.) Lyons.	. . . . .	. . . . .	. . . . .	See *Oil of Cajuput.*
Niaouli of New Caledonia.	0.908–0.922	. . . . .	Pinene, cineol, terpineol, valeric aldehyde (?), benzaldehyde (?), limonene (?), terpineol, terpinyl valerianate, acetic and butyric acid esters.	"Gomenol" or oil of niaouli.
C. leucadendron. var. *lancifolia.*	0.955	—3°38′	Cineol.	
C. acuminata (Muell.) Rusby.	0.892	—15°20′	Cineol.	Odor reminds slightly of juniper berries.
C. decussata (R. Br.) Rusby.	0.938	. . . . .	. . . . .	Odor and taste very similar to those of cajuput oil.
C. ericifolia (Sm.) Lyons.	0.899–0.902	. . . . .	. . . . .	Similar to cajuput oil.
C. genistifolia (Sm.) Rusby.				
C. linarifolia (Sm.) Rusby.	0.898–0.903	. . . . .	. . . . .	Odor cajuput-like, but somewhat resembling that of mace and mint.
C. squarrosa (Sm.) Rusby.	. . . . .	. . . . .	. . . . .	Oil has an unpleasant taste.
C. uncinata (R. Br,) Rusby.	0.925	+1°40′	Cineol, terpineol (?).	Cajuput-like, also resembling that of spike and rosemary.
C. Wilsonii (Muell.) Rusby.	0.925			
Eucalyptus.

Anethum.				
A. Sowa Roxb. E.L.	0.948–0.970	+41° to 47°	Dill-apiol	Oil of East Indian and Japanese dill.
Japanese.	0.964	+50°30′		
Angelica.				
A. refracta Schmidt.	0.910	. . . . .	Oxypentadecylic acid.	Japanese angelica oil resembles somewhat musk.
A. Archangelica L.				
Root.	0.857–0.918	+16° to 32°	Pinene(?), cymene(?), phellandrene, sesquiterpene (?), oxypentadecylic acid.	The odor is aromatic, pepper like, with an admixture of musk.
Seed.	0.856–0.890	+11° to 12°	Phellandrene, methyl ethyl acetic acid, oxymyristic acid.	
Herb.	0.870–0.890	+8° to 21°		
Ferula.				
F. fœtida (Bunge) Regel.	0.975–0.990	—9°15′	Pinene, $C_7H_{14}S_2$, $C_{11}H_{20}S_2$, $(C_{10}H_{16}O)^n$, $C_8H_{16}S_2$, $C_{10}H_{18}S_2$.	
F. rubricaulis Boiss. / *F. galbaniflua* G. Schaïr.	0.910–0.940	+20° to —10°	Pinene, cadinene.	Galbanum oil.
F. Sumbul Hook.	0.954–0.964	. . . . .	. . . . .	Oil of sumbul has a musk-like odor.
Dorema.				
D. Ammoniacum Don.	0.891	. . . . .	. . . . .	Oil of gum ammoniac resembles the gum resin as to odor; also angelica.
Peucedanum.				
P. Oreoselinum (L.) Moench.	0.843	. . . . .	Terpene.	"Bergpetersilienöl" has a strong aromatic odor somewhat resembling juniper.
P. officinale L.	0.902	+29°4′	. . . . .	Oil from root.
P. Ostruthium Koch.	0.877	. . . . .	. . . . .	The oil from the root resembles angelica oil as to odor.
P. graveolens B. et H.	0.895–0.915	+75° to 80°	Carvone, limonene, phellandrene, pinene (?), dill-apiol, paraffin.	
P. grande Clark.	0.9008	+36°	. . . . .	The oil from the fruit resembles carrot oil.
P. sativum Benth.	0.87–0.89	—0°15′ to —0°30′	Propionic acid (?), octyl ester of butyric acid, ethyl alcohol.	The oil of the fruit of parsnip appears to differ materially with the degree of maturity of the fruit.
Heracleum.				
H. sphondylium L.	0.80–0.88	+0°15′ to 0°16′	Ethyl butyrate, hexyl acetate, octyl acetate, capronate and laurinate, methyl and ethyl alcohols.	
H. giganteum L.	. . . . .	. . . . .	Ethyl butyrate, methyl and ethyl alcohols.	
Daucus.				
D. Carota L.	0.870–0.923	—13° to —37°	Pinene (?).	Carrot oil from the fruit.
Washingtonia.				
W. longistylis (Torr.) Britton.	1.0114	. . . . .	Anethol.	Sweet cicely or sweet anise oil.
Order **Pirolaceæ.**				
Hypopitys.

Blumea.				
B. balsamifera DC.	. . . . .	. . . . .	Borneol.	Of interest principally for the reason that it yields Borneo camphor, used for ritualistic and medicinal purposes in the Orient.
B. lacera DC.	0.9144	—66°	Borneol (?).	
Helichrysum.				
H. Stœchas DC.	. . . . .	. . . . .	Pinene (?).	
Inula.				
I. Helenium L.	. . . . .	. . . . .	Alanto-lactone, alantolic acid, alantol $(C_6H_8O)_x$.	Oil of elecampane is solid at ordinary temperature. It is used principally for the preparation of alanto-lactone, the helenin of Gerhardt.
Osmitopsis.				
O. asteriscoides Cass.	0.931	. . . . .	Camphor (?), cineol (?).	The odor suggests that of cajuput oil.
Ambrosia.				
A. artemisiifolia L.	0.870	—26°	. . . . .	Ragweed oil.
Anthemis.				
A. nobilis L.	0.905–0.915	+1° to 3°	Isobutyl, amyl, and hexyl esters of butyric, angelic, and tiglic acids, methycrylic acid (?), anthemol, paraffin.	Roman chamomile oil.
A. Cotula L.	0.858	. . . . .	Acid, m.-p. 58° C.	
Achillea.				
A. millefolium L. Flowers.	0.905–0.925	. . . . .	Cineol, azulene.	Oil of milfoil.
Roots.	. . . . .	. . . . .	Sulphur compound.	
A. nobilis L.	0.970			
A. moschata Jacq.	0.932–0.934	. . . . .	Cineol.	
A. tanacetifolia Allen.	0.924	. . . . .	. . . . .	Odor is suggestive of tansy.
A. ageratum L.	0.849	. . . . .	$C_{26}H_{44}O_3$ (?).	
Matricaria.				
M. Chamomilla L.	0.930–0.940	. . . . .	Paraffin, cœrulein, caprinic acid.	Oil of German chamomile.

Order **Compositæ.**	Sp. gr.	$(\alpha)_D$	Constituents.	Remarks.
Chrysanthemum.				
C. Parthenium (L.) Pers.	0.908–0.960	. . . . .	Borneol, camphor, terpene.	Oil of feverfew.
C. balsamita L.	0.943–0.949	—43° to —53°	Paraffin (?).	
Tanacetum.				
T. vulgare L.	0.925–0.940	+30° to 45°	Borneol, camphor, terpene(?), thujone, thujyl alcohol (?).	Oil of tansy is said to be poisonous, producing *la rage tanacetique.*
Pyrethrum.				
P. indicum Cass.	0.885	. . . . .	. . . . .	Kiku oil is used in Japan as a popular remedy.
Artemisia.				
A. vulgaris L.				
Herb.	0.907	. . . . .	Cineol.	
Root.	. . . . .	. . . . .	. . . . .	The root oil is semisolid.
A. Dracunculus L.	0.900–0.945	+2° to 9°	Methyl chavicol.	Oil of estragon.
A. pauciflora (Ledeb.) Webb.	0.915–0.940	. . . . .	Cineol, terpene.	Oil of Levant wormseed is obtained as a by-product in the manufacture of santonin.
A. Absinthium L.	0.925–0.955	. . . . .	Thujone, thujyl alcohol, thujyl acetate, isovalerianate and palmitate, pinene (?), phellandrene, cadinene, blue oil.	Wormwood oil, used in the preparation of absinthe, possesses toxic properties.
A. gallica Willd.	. . . . .	. . . . .	Camphor (?).	
A. Barrellieri Bess.	0.923	. . . . .	Thujone.	
A. glacialis L.	0.964	. . . . .	Fatty acid, m.-p. 16°C.	
Erechtites.				
E. hieracifolia (L.) Raf.	0.838–0.855	—1° to +2°	Terpene.	Oil of fireweed.
Petasites.				
P. Petasites (L.) Karst.	0.944	+2°18′	. . . . .	"Pestwurzöl."
Arnica.				
A. montana L.				
Root.	0.990–1.000	—1°58′	Caprylic and capronic acids (?), isobutyric and formic acids, phloryl isobutyrate, phlorol methyl ether, hydrothymoquinone methyl ether.	Arnica root oil.
Flowers.	0.897–0.906	. . . . .	Palmitic and lauric acids, paraffin (?)	A butyraceous mass.
Saussurea.				
S. Lappa Clark.	0.982–0.987	+15° to 16°	Phenol (?).	Oil of costus root resembles elecampane and violet.
Carlina.				
C. acaulis L.	1.030	. . . . .	Sesquiterpene (?), sesquiterpene hydrate (?), stearoptene.	Oil of carline thistle.
Spæranthus.				
S. indicus L.				

Constituents of Volatile Oils.—The impossibility of classifying the volatile oils chemically has been alluded to. Although but five elements, viz., carbon, hydrogen, oxygen, sulphur, and nitrogen, have been found in volatile oils thus far, a special classification of their constituents is impracticable. In this brief discussion of the chemical constituents they have been arranged according to a rational classification of organic chemical substances at large. The hydrocarbons, as basal compounds, are taken up first, and the numerous series are arranged in groups according to their degree of saturation. Of halogen derivatives of the hydrocarbons, there are none. The oxygenated compounds are again considered primarily according to the degree of saturation of the underlying hydrocarbons, and secondarily in series of the genetically related tribes of alcohols, aldehydes, ketones, acids, etc. Of sulphur and nitrogen derivatives, there are but few thus far.

For detailed information concerning these compounds, the reader should consult the larger hand-books on organic chemistry and the special monographs by Heusler, *Die Terpene* (1896), which has been translated into English and brought up to date by Pond in his *Chemistry of the Terpenes* (1902).

Hydrocarbons.—1. Of the formula of saturation C_nH_{2n+2}. This formula is represented by but one series, namely, the limit, or paraffin, or marsh-gas, or methane series. Unless

the stearoptene from rose oil, and like stearoptenes from other oils, prove to be very complex mixtures, this series is at present but sparingly represented in volatile oils. The lowest member thus far obtained and identified is the *n*-heptane, C_7H_{16}, which is the principal constituent of the oil of *Pinus Sabiniana* Douglas, the digger's pine of California. This coniferous oil differs, therefore, materially from the oils of its congeners, which contain largely pinene, $C_{10}H_{16}$, and related compounds. Besides rose oil, the oils of wintergreen and sweet birch, and some others, are known to contain minute quantities of solid paraffin hydrocarbons.

2. Of the formula of saturation C_nH_{2n}. Of this formula, one unsaturated chain series (ethylene) and several saturated cyclic series, the polymethylene series, are known. No definitely established representatives of any of these are to be found in volatile oil literature, although derivatives of such are among the most important constituents—*e. g.*, menthol, an alcohol of the hydrocarbon menthane, $C_{10}H_{20}$, a member of the hexamethylene series.

3. Of the formula of saturation C_nH_{2n-2}. Series of chain hydrocarbons with a triple bond (acetylene), two double bonds (propadiene series); unsaturated, monocyclic series with one double bond (cyclopropene, cyclobutene, etc., series), and saturated dicyclic series (dicyclobutane, etc.), are known as such or through their derivatives. In volatile oils neither the acetylene nor the propadiene series are represented thus far, though derivatives of the latter are known as important constituents—*e. g.*, the alcohols geraniol and linalool, the aldehyde citral, all of which are derived from chain hydrocarbons $C_{10}H_{18}$. Menthene, a monocyclic, unsaturated hydrocarbon $C_{10}H_{18}$, possibly occurs in peppermint oil. A dicyclic, unsaturated hydrocarbon has not yet been identified, although borneol and camphor are now generally regarded as being derived from such a hydrocarbon. The hydrocarbons of this class are sometimes known as dihydroterpenes, $C_{10}H_{16} + H_2$. According to the Geneva Congress nomenclature, the designation terpene ($\approx$ menthene) is given to such hydrocarbons of this class which can be regarded as tetrahydrocymenes or at least have a similar general configuration.

4. Of the formula of saturation C_nH_{2n-4}. This formula is represented by numerous series. That group of hydrocarbons with 10 carbon atoms, namely, $C_{10}H_{16}$, irrespective of the series to which they belonged, has been designated by the group name terpene. According to the Geneva Congress nomenclature, some of these terpenes are terpadienes, the designation terpene, according to that style of nomenclature, being restricted to certain hydrocarbons, $C_{10}H_{18}$. The camphenes, terpilenes, etc., of older authors are lesser groups of hydrocarbons, $C_{10}H_{16}$.

It is noteworthy that practically all hydrocarbons of this formula of saturation found in volatile oils contain 10 carbon atoms. In the literature of volatile oils they have played so important a rôle that its chemical chapters have commonly been regarded as synonymous with the literature of the terpenes (old style) and their derivatives (camphors, etc.).

According to series, this group of terpenes can be classed into chain hydrocarbons with three double bonds (*e. g.*, myrcene) or their structural equivalent; into monocyclic hydrocarbons with two double or one treble bond (*e. g.*, the terpinolenes); into dicyclic hydrocarbons with one double bond (*e. g.*, pinene, limonene, camphene); and into saturated tricyclic hydrocarbons. The last, though stable, would probably be characterized by chemical indifference and therefore escape detection. The first is characterized, on the other hand, by great instability. Its representatives might be expected to undergo decomposition even in the process of distillation of the oil, hence the only probable representative, myrcene, is of recent discovery. It and its more immediate isomers have also been designated aliphatic terpenes.

Many of the representatives of the terpene group exist in different optical modifications, namely, dextrogyrate and lævogyrate. Mixtures of equal quantities of these are inactive. In some instances there may be optical inactivity by inner compensation (dipentene?). On account of this isomerism, subgroups of terpenes are commonly referred to. Such subgroups are:

Pinene.—This is liquid and widely distributed. The principal source of dextropinene is American turpentine oil, that of lævo-pinene French turpentine oil. It is characterized by its hydrochloride, $C_{10}H_{16}.HCl$, the artificial camphor of older literature, and by its nitrosochloride, $C_{10}H_{16}NOCl$, and nitrolamine bases. From the nitrosochloride it can be regenerated in the optically inactive form. When pure it boils at about 155° C. (311° F.).

Camphene.—Although solid, it has been isolated as such but from one oil (*Abies Sibirica*). By its conversion into isoborneol its presence in other oils has been ascertained (citronella oil, camphor oil, lemon oil, ginger oil, and Japanese valerian oil). Artificially it can be obtained from pinene hydrochloride, $C_{10}H_{16}.HCl - HCl = C_{10}H_{16}$. It melts at about 48°–49° C. (118.4°–120.2° F.) and boils at about 160°–161° C. (320°–321.8° F.). There are two optical modifications.

Fenchene.—Though not yet isolated from volatile oils, it is supposed to be a constituent of several turpentine oils. It is liquid, boils at about 155°–156° C. (311°–312.8° F.), and exists in two optical modifications.

Limonene.—Like pinene, it formerly had a different name for each occurrence—*e. g.*, carvene, the *d*-limonene of caraway oil, citrene, the same hydrocarbon in lemon oil, etc. Next to pinene, it is the most widely distributed terpene in nature. Dextrogyrate limonene constitutes the bulk of the oils of orange, lemon, and erigeron, about 50 per cent. of caraway oil, etc. Lævogyrate limonene constitutes the bulk of a pine-needle oil and about 50 per cent. of American spearmint oil. The inactive modification is generally designated

Dipentene, which also has been found in many oils and named according to source—*e. g.*, cinene, cajuputene, etc. The hydrocarbons of this group are liquid, boil at about 175° C. (347° F.), and are characterized by their tetrabromides, $C_{10}H_{16}Br_4$, and by their nitrosochlorides and nitrolamine derivatives.

Sylvestrene, known thus far only in its dextrogyrate modification, is found in the Swedish and also the Russian turpentine oil. It is liquid, and boils at about 176°–177° C. (348.8°–350.6° F.). It is characterized by its nitrosochloride and nitrolamine base. Carvestrene, obtained artificially by the distillation of carvylamine hydrochloride, is supposed to be identical with optically inactive sylvestrene. It exists in two stereo-isomeric forms, ortho-carvestrene and pseudo-carvestrene.

Terpinolene has not yet been found in nature. It is exceedingly unstable and has not been prepared in pure form. It boils at about 185°–190° C. (365°–374° F.). It is characterized by its tetrabromide.

Phellandrene derives its name from *Phellandrium aquaticum*, in which dextro-phellandrene was first found. The lævogyrate variety is quantitatively an important constituent of therapeutically inferior eucalyptus oils (*E. amygdalina*, etc.). It is liquid, boils at about 170° C. (338° F.), and is characterized by its so-called nitrosite, $C_{10}H_{16}.N_2O_3$. See test under Eucalyptus Oil.

Terpinene has been identified in cardamom oil and in marjoram oil by means of its nitrosite, yet there exists doubt as to its pre-existence in oils. It is formed from pinene by the action of sulphuric acid (see Terebene). By some it is regarded as the pseudo form of limonene. It boils at about 179°–181° C. (354.2–357.8° F.) and is optically inactive.

Other representatives of this group are thujene or tanacetene; the readily resinifiable terpene from the resin of Indian hemp; the hydrocarbon from pulegol ($C_{10}H_{18}O - H_2O = C_{10}H_{16}$); fenchelene; euterpene; tricyclene; bornylene; sabinene.

The close relationship of many of these hydrocarbons finds expression in the readiness with which some of them are converted into their isomers. Thus, pinene can be converted indirectly into camphene, limonene, terpinene, and terpinolene.

Though quantitatively among the most important constituents of volatile oils, from the standpoint of therapeutics and flavor they can be regarded generally as diluents rather than essential constituents. Thus the eucalyptus oils are regarded as superior in the proportion in which cineol predominates and phellandrene is reduced in quantity. For liquors and essences, the terpenes are frequently removed because of their sparing solubility in dilute alcohol. These products are designated concentrated or terpeneless oils—*e. g.*, concentrated oil of caraway for the manufacture of "Kuemmel," and terpeneless oil of lemon for the manufacture of essence of lemon.

5. Of the formula of saturation C_nH_{2n-6}. The best-known series of this formula is a monocyclic series with three double bonds, the benzene series. Of this series, a single representative, the cymene $C_{10}H_{14}$, has been found in the oils of several species of *Thymus*, *Monarda*, etc. It is of interest as such, and because it is the hydrocarbon underlying the two isomeric phenols thymol and carvacrol; also because of its structural relation to some of the terpenes, which as a class have been designated dihydrocymenes. With most terpenes, however, this relation is empirical but not structural.

A group of hydrocarbons, the sesquiterpenes, $C_{15}H_{24}$ (= one and a half terpene = $C_{10}H_{16} + C_5H_8$), also come under this formula of saturation. As is the case with the terpenes, this name is applied to all hydrocarbons $C_{15}H_{24}$ irrespective of the series to which they may belong. The following types, however, should be distinguished: (*a*) chain compounds with 4 double bonds or their equivalents (the sesquiterpene from citronella oil is a possible representative); (*b*) monocyclic hydrocarbons with 3 double bonds (zingiberene); (*c*) dicyclic hydrocarbons with 2 double bonds (cadinene, caryophyllene, etc.); (*d*) tricyclic hydrocarbons with 1 double bond. (clovene, etc.); (*e*) tetracyclic saturated hydrocarbons. Like the saturated members of the terpene group, those of the sesquiterpene group have no marked chemical characteristics and have thus far failed of detection if they exist in volatile oils. Those of type *a* being very unstable, may decompose at least in part during the process of distillation of the oil. Most of the numerous sesquiterpenes, known by fanciful names, and not characterized chemically, are in all probability representatives of the series under *c* and *d*.

Cadinene derives its name from oil of cade. If its hydrochloride is characteristic of this hydrocarbon, it occurs widely distributed. It may be, however, that other compounds yield cadinene dihydrochloride when treated with hydrochloric acid. Characteristic of this hydrocarbon appears to be its nitrosochloride.

Caryophyllene derives its name from oil of cloves, of which it constitutes about 10 per cent. It is also found in the oil of *Canella alba* and oil of pepper. It is readily characterized by its blue nitrosite.

Humulene has been isolated from oil of hops and is characterized by its nitrosochloride.

Other sesquiterpenes are clovene, obtained by the dehydration of caryophyllene hydrate, $C_{15}H_{25}OH$; cedrene, obtained in like manner from cedrol, also preëxisting in cedarwood oil; α- and β- santalene.

The sesquiterpenes are all liquid, so far as known; have high boiling-points, 240°–260° C. (464°–500° F.); and as a rule are difficultly soluble in alcohol. Though formerly regarded as useless and objectionable constituents in many volatile oils, some are greatly appreciated in perfumery as giving body to an aroma; others are important as giving rise to hydrates or camphors—*e. g.*, cubeb camphor in old cubebs exposed to a moist atmosphere, etc.

6. Of the formula of saturation C_nH_{2n-8}. Of the numerous series of hydrocarbons, but a single series appears thus far to be represented by a single member, viz., styrene, $C_6H_5CH{=}CH_2$, a hydrocarbon with a benzene nucleus and an unsaturated side chain. It is characterized by its dibromide, $C_6H_5CHBrCH_2Br$. It occurs in storax oil and xanthorrhœa resin oil. Possibly it does not preëxist in the plant, but is a decomposition-product of cinnamic acid.

7. Of the formula of saturation C_nH_{2n-10}. Here also but a single representative can be mentioned, and that one of recent discovery, viz., naphthalene.

8. Of still less saturated hydrocarbons, the diterpenes $C_{20}H_{32}$, the triterpenes $C_{30}H_{48}$, and the tetraterpenes $C_{40}H_{64}$, need only be mentioned. Very little is known about them and their existence in volatile oils is still doubtful. If they occur in oils, they are more likely to be polymerization-products of lesser hydrocarbons than plant products isolated from plant organs by steam or water distillation. Amyrin is regarded as a hydrate of a triterpene.

Oxygen Derivatives of Hydrocarbons.—Halogen derivatives have thus far not been found among volatile plant products, hence the presence of chlorine in a commercial oil of bitter almonds may serve as a means of detecting an impure artificial product.

Of the hydroxy substitution-products of hydrocarbons and their dehydration-products—alcohols, aldehydes, ketones, acids, esters, lactones, oxides—a very large number have been isolated from volatile oils, thoroughly studied and characterized. Many of them are quantitatively significant—*e. g.*, menthol in peppermint oil; others, though quantitatively not so important, are regarded therapeutically essential—*e. g.*, cineol in eucalyptus and other oils, thymol, etc.; still others, which play quantitatively an insignificant rôle, are of greatest importance as flavoring agents. Thus, lemon oil was not long ago classed with the so-called hydrocarbon oils supposed to be free from oxygenated constituents. To-day certain manufacturers regard the 90 per cent. of limonene as worse than worthless, and desire the remaining 10 per cent. of citral and other oxygenated constituents of the oil The peculiar flavor of rose oil is due in part to a very small percentage of constituents as yet unknown.

1. Hydroxy Substitution-products of the Paraffin Hydrocarbons (Hydrocarbons C_nH_{2n+2}) and their Dehydration-products.

Number of carbon atoms.	R′OH	R″(OH)$_2$—H$_2$O		R‴(OH)$_3$—H$_2$O	R⁗(OH)$_4$, etc.

15	. . . . .	. . . . .	. . . . .	. . . . .	$C_{14}H_{28}(OH)COOH$ Oxypentadecylic acid
16	. . . . .	. . . . .	. . . . .	$C_{15}H_{31}COOH$ Palmitic	

The above table clearly reveals the incorrectness of the statement that most of the constituents of volatile oils contain 10 carbon atoms ; in other words, are terpenes or their immediate derivatives.

These compounds can be studied as representatives of homologous series—*e. g.*, the alcohols, aldehydes, etc. ; or they can be studied in groups of compounds having the same number of carbon atoms—*i. e.*, butyl alcohol, butyric aldehyde, butyric acid.

Inasmuch as but few, if any, deductions can be drawn as yet from the occurrence of members of the same homologous series in the same or related plants, this plan will not be adopted here, though chemically the simpler one. On the other hand, a simple relation between butyric alcohol, aldehyde, and acid manifests itself at once, and the occurrence of any two of them or of all three can easily be explained from the original formation of one by the plant.

(1 and 2) The question whether methyl and ethyl alcohols exist as such in the plants is still an open question. They enter the oil in but minute traces, since most volatile oils are made by distillation with steam or water, and these alcohols are more readily soluble in the water than in the oil.

As myristic ester, methyl alcohol occurs in orris oil ; as salicylate it is widely distributed in nature, though but few plants produce it in sufficient quantity to yield commercial oils, namely, gaultheria and sweet birch (see Oil of Wintergreen). An assay of senega root was at one time based on its methyl salicylate content, but was found unsatisfactory.

Ethyl alcohol has been isolated from a number of aqueous distillates of plants, notably of *Heracleum* species, in which it is found as butyric ester. As oxymyristic and veratric esters it occurs in *Sabadilla officinalis*, as cinnamic ester in *Liquidambar orientalis.*

Acetic aldehyde has been found in several oils ; and acetic acid is widely distributed as ester : hexyl, octyl, menthyl, linalyl, geranyl, bornyl, terpinyl, etc., acetates. These will receive attention under the respective alcohols.

(3) On account of its ready solubility in water, acetone is found in traces only; propionic acid has been found as such and as ester.

(4) Isobutyl alcohol occurs as isobutyrate and as angelic ester in Roman chamomile. A butyric aldehyde has been isolated from a commercial eucalyptus oil, from which it should be removed before the oil is used medicinally, because of the irritation it produces when inhaled. Butyric acid has been isolated from a number of oils, free and as ester: hexyl, octyl, linalyl, terpinyl esters. Isobutyric acid has also been found as ester.

(5) Traces of amyl alcohol have been found in a eucalyptus oil and in American peppermint oil. Valerianic aldehyde has been found in eucalyptus and cajuput oils. Valerianic acid occurs as hexyl and octyl esters in male fern, as geranyl and linalyl esters in sassafras, as bornyl ester in several plants.

(6) Hexyl alcohol occurs as acetate, butyrate, valerianate, caproate, caprylate, pelargonate, as tiglate and angelate—*e. g.*, in heracleum, arnica, male fern, and Roman chamomile (see these oils for respective constituents). Like some of the lower aldehydes, caproic aldehyde has been found in eucalyptus oil. Caproic acid has been found as such and as hexyl, octyl, etc., esters.

(7) Methyl amyl ketone has been isolated from clove oil, to which it is supposed to impart the finer clove aroma.

(8) Octyl alcohol has been found as acetate, butyrate, valerianate, caproate, œnanthate, caprylate, caprinate, and laurinate in much the same oils in which the corresponding hexyl esters occur. Caprylic acid is found with caproic acid.

(9) Methyl heptyl ketone and methyl nonyl ketone are found in oil of rue; the former predominates in the Algerian oil, the latter in the Spanish. Pelargonic acid has been found as ethyl, amyl, hexyl, and octyl esters.

(10) Capric acid occurs as ethyl, amyl, and octyl esters.

(11) See paragraph (9).

(12) Lauric aldehyde has been found in rue; lauric acid as such and as octyl ester.

(14) Myristic acid occurs as such and as methyl ester in orris oil. Oxymyristic acid in the oil of *Archangelica officinalis*, its ethyl ester in *Sabadilla officinalis*.

(15) Oxypentadecyclic acid also occurs in *Archangelica officinalis*.

(16) Palmitic acid has been obtained from several oils.

2. Oxygen Derivatives of Hydrocarbons C_nH_{2n}.—*a*. The number of oxygen derivatives of the olefine series of hydrocarbons found thus far in volatile oils is not large. In the order of the number of carbon atoms, the following individuals and groups should here be mentioned: methacrylic acid, $CH_2{:}C(CH_3)COOH$, which occurs as an ester in Roman chamomile; the two stereoisomeric angelic and tiglinic acids, $CH_3CH{:}C(CH_3)COOH$, which also occur in the same plant; methyl heptenone, $CH_3C(CH_3){:}CHCH_2CH_2COCH_3$ (methyl-2-heptene-2-one-6), which has been isolated from several andropogon oils; citronellol, $C_9H_{17}CH_2OH$, and its corresponding aldehyde, citronellal, $C_9H_{17}CHO$, the former being a constituent of the oil of *Andropogon schœnanthus*, rose oil, and rose geranium oil, the latter of two andropogon oils, of several eucalyptus oils, of several oils of the *Citrus* genus, etc.; finally, oleic aldehyde, $C_8H_{17}CH{:}CH[CH_2]_7CHO$, and its corresponding acid, oleic acid, both being found in orris oil.

b. Of the hexamethylene series a still smaller number of compounds are known to occur in volatile oils, but two of these are of the greatest interest. The alcohol menthol, $C_{10}H_{19}OH$, and its corresponding ketone, the menthone, $C_{10}H_{18}O$, occur in peppermint oil, the former both as free alcohol and as ester. The finer aroma, and hence the greater commercial value, of peppermint oil is supposed to be largely due to the percentage of esters present. For menthol assay, free and as ester, see Oil of Peppermint.

The diatomic alcohol terpin, $C_{10}H_{18}(OH)_2$, or rather its hydrate, the terpin hydrate of the U. S. P., is occasionally met with in pinene-containing oils. It is not supposed to have distilled over with the oil from the plant, but to have formed in the distilled oil by hydration, viz., $C_{10}H_{16} + 3H_2O = C_{10}H_{18}(OH)_2.H_2O$. The terpin hydrate of the market, however, is not obtained from these oils, in which its formation appears to be largely accidental, but by the indirect hydration of pinene (turpentine oil) with water and nitric acid. A dehydration-product of the terpin $C_{10}H_{18}(OH)_2 - H_2O = C_{10}H_{18}O$, the cineol or eucalyptol, is widely distributed. It is the principal constituent which gives medicinal value to the eucalyptus oils. Its presence in larger percentage in English lavender oil causes this to be more sought as a perfume by English-speaking people than the French

oil, which contains much more linalyl acetate. Cineol or eucalyptol is also official as such (see Eucalyptol).

c. There are several oxygen derivatives of hydrocarbons C_nH_{2n} that have not yet been subclassified—*e. g.*, hedeomol.

3. Oxygen Derivatives of Hydrocarbons C_nH_{2n-2}.—*a.* Of the chain series, only that one with two double bonds is represented, and this only by the two isomeric alcohols, $C_{10}H_{17}OH$, geraniol and linalool, and by citral, $C_{10}H_{16}O$, the aldehyde corresponding to the former. All these compounds, though comparatively new in volatile oil literature, are found to be fairly widely distributed. Geraniol derives its name from oil of rose geranium, from which it was first obtained, linalool from oil of lignaloe. Both are found as such and as ester. Linalyl acetate is regarded as the principal constituent of bergamot oil, which is assayed and valued according to its linalyl acetate content. French lavender oil is also rich in this ester, whereas the English oil contains but a small per cent., yet the latter oil has a greater commercial value.

Citral is found to the extent of 70 to 80 per cent. in lemongrass oil, which is the principal source of the commercial article. With citronellal it is found in lemon oil, of which it is an essential constituent, though present in but small quantity. Being more soluble in dilute alcohol than limonene, it enters largely into the water-soluble extracts of lemon. It is also a principal constituent of the concentrated and terpeneless oils of lemon. As a lemon flavor, however, it cannot be displaced by citral from lemongrass oil, since the peculiar lemon flavor is not due to citral alone. Moreover, lemongrass oil appears to contain other aldehydes than citral, which are not readily separated, and which influence the odor of the commercial citral obtained from this source.

b. Of monocyclic unsaturated compounds, the isomeric terpineols should be mentioned. These alcohols, $C_{10}H_{17}OH$, derive their name from terpin hydrate, from which one of them is obtained artificially on a commercial scale: $C_{10}H_{18}(OH)_2—H_2O = C_{10}H_{17}OH$. (Compare the corresponding reaction resulting in the formation of cineol.) It is used in the preparation of artificial lilac and other perfumes. The four isomeric terpineols occur in a variety of oils, both free and as ester, principally as acetate.

To this group belongs the ketone, pulegone, $C_{10}H_{16}O$, the principal constituent of pennyroyal oil; possibly also dihydrocarvone.

c. To the group of dicyclic saturated compounds belong the alcohol borneol, $C_{10}H_{17}OH$, and its corresponding ketone camphor, $C_{10}H_{16}O$; also thujyl alcohol and thujone, isomeric with the former. Borneol occurs both as such (*Dryobalanops camphora*—Borneo camphor) and as ester, principally as acetate. In the latter form it is a principal constituent of the pine-needle oils. The artificial ester is sold as artificial pine-needle oil (*Tannennadelöl*). Camphor is the principal constituent of the oil of *Laurus camphora*, but enters the market principally as such, having been isolated from the oil. Its artificial production on a large scale from turpentine oil is promised in the near future. All the above related compounds are found widely distributed both in their dextrogyrate and lævogyrate modifications.

Isomeric with camphor is also fenchone, a ketone found in fennel oil, from which it derives its name.

d. A heterocyclic compound, the furol or furfuric aldehyde, $C_4H_3O.CHO$, remains to be mentioned. It was first found in oil of cloves, and, since it has the property of gradually becoming darker, it has been surmised that the darkening of oil of cloves is due to the presence of this unsaturated aldehyde.

e. There are also several compounds that cannot be subclassified—*e. g.*, sedanolid, etc.

4. Oxygen Derivatives of Hydrocarbons C_nH_{2n-4}.—*a.* None of the several series of chain hydrocarbons are thus far represented among the known constituents from volatile oils. Like myrcene, the so-called aliphatic terpene, they are, in all probability, rather unstable, and hence will either be decomposed in the preparation of the volatile oil or by the reagents used in their study.

b. A monocyclic compound with two double bonds is the diketone thymoquinone, $C_{10}H_{12}O_2$. It occurs as such in the monarda oils; also, combined with hydrothymoquinone, as thymoquinhydrone, a pigment which dissolves in the phenols of these oils with a reddish-brown color. The color of red oil of thyme is probably also due to the same pigment.

c. Dicyclic, with one double bond, is carvone according to Baeyer's formula. This ketone, $C_{10}H_{14}O$, in its dextrogyrate modification is the principal constituent of caraway

oil; its lævogyrate modification occurs in spearmint oil. Under the name of *Oleum Carvi*, carvone is official in the P. G.

d. Among the unclassified substances of this group are kessyl alcohol, $C_{10}H_{15}OH$, and its isomer sabinol, formerly supposed to have the formula $C_{10}H_{17}OH$. The former is found as such and as valerianic ester in the oil of kesso root, the latter as such and as acetate in oil of savin (*Juniperus sabina*), of which the ester is regarded as the principal constituent.

An important group of constituents belonging here are the sesquiterpene hydrates, most of which appear to be alcohols: $C_{15}H_{24} + H_2O = C_{15}H_{25}OH$. These are evidently widely distributed, but few are as yet well characterized. Santalol, the principal constituent of the oil of *Santalum album*, is possibly the most important of this group from a pharmaceutical point of view. Some of these, possessing crystalline form, are known as camphors. Thus, ledum camphor from *Ledum palustre*, and cubeb camphor from oil of cubebs. The latter is found primarily, if not exclusively, in the oil from old cubebs, and is supposed to be the product of hydration of the sesquiterpene formed by long storage of the berries.

5. Oxygen Derivatives of Hydrocarbons C_nH_{2n-6}.—Of the large number of chain and cyclic series of hydrocarbons of this formula of saturation, oxygen derivatives of but one series, viz., the benzene series, are known.

a. Of the hydroxy derivatives of the benzene nucleus, the phenols, the isomers thymol and carvacrol are widely distributed. Thymol derives its name from *Thymus vulgaris*, but the principal commercial source is ajowan oil, at times horsemint oil. Carvacrol, which derives its name from the isomeric ketone carvone, from which it can readily be obtained, is found principally in oil of wild bergamot belonging to the same genus with horsemint.

Of diatomic phenols, hydrothymoquinone has been found as such and in the form of the pigment thymoquinhydrone (comp. thymoquinone) in the monarda oils. As dimethyl ether it has been found in arnica root oil, as ethyl ether in star-anise oil.

Of the phenols with a lesser number of carbon atoms, *p*-cresol has been found as methyl ether in ylang-ylang oil; phlorol, as isobutyric ester and also as methyl ether in arnica root oil.

b. The oxygen compounds, in which the oxygen is connected with the saturated fatty side chain, are more numerous. They are mostly aldehydes and acids. The simplest representative, the benzaldehyde, is formed whenever amygdalin-containing drugs are submitted to distillation after maceration to permit hydrolysis of the glucoside. Amygdalin is very widely distributed, but not often present in sufficient quantity to yield sufficient benzaldehyde to separate as oil from the aqueous distillate. The principal natural sources for commercial benzaldehyde (bitter almond oil) are the kernels of the bitter almond, the peach, and the apricot. Inasmuch as benzaldehyde is very prone to oxidation, oils containing it are apt to contain benzoic acid as well, especially when old and exposed to air.

Hydroxy benzoic aldehyde or salicylic aldehyde is found in spiræa oil. Salicylic acid is especially widely distributed as methyl ester, mostly the product of hydrolysis of a glucoside. In commercial quantities it was first obtained from wintergreen leaves, hence oil of wintergreen. At present the principal oil, consisting almost entirely of methyl salicylate, is oil of sweet birch. Most plants, however, do not contain sufficient glucoside to yield commercial oils.

Cuminic or *p*-isopropyl benzaldehyde occurs in cicuta and eucalyptus oils.

Anisic or *p*-methoxybenzaldehyde occurs in old anise and fennel oils in which, together with anisic acid, it is formed by the oxidation of anethol. Vanillin or *m*-methoxy-p-hydroxybenzaldehyde results upon oxidation of coniferyl alcohol, a product of hydrolysis of the glucoside coniferin. Heliotropin, the methylene ether of a diatomic phenol of benzaldehyde (1 : 2 : 3), and vanillin occur as such in spiræa oil.

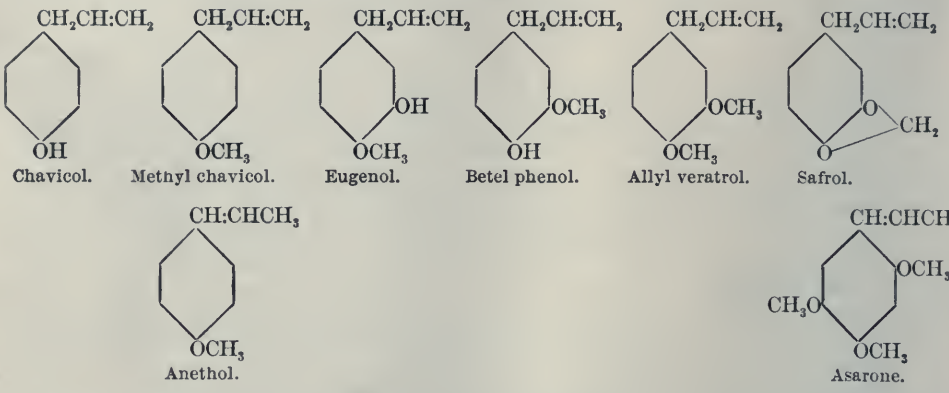
The only ketone of the benzene series thus far found in a volatile oil is the anisic ketone, $C_6H_4.OCH_3[^1],CH_2CO.CH_3[^1]$, reported to occur in anise and fennel oils.

In addition to the acids of this series already referred to, namely, benzoic, salicylic, and anisic acids, veratic acid, $C_6H_3(OCH_3)_2COOH$, found in cevadilla seed oil, should be mentioned.

6. Oxygen Derivatives of Hydrocarbons C_nH_{2n-8}.—Here also oxygen deriva-

tives of but one series of hydrocarbons, namely, of those containing a benzene nucleus with an unsaturated side chain, are known to exist in volatile oils.

a. Those of the nature of phenols and phenol ethers are the more numerous and important. Their relationship is best expressed by the following formulas:



Heated with alcoholic potassium hydroxide solution the allyl compounds (upper series) are converted into the corresponding propenyl compounds (lower series), thus methyl chavicol into anethol, eugenol into isoeugenol, etc., but whereas the latter are more stable toward this reagent, their occurrence in the vegetable kingdom does not appear to be so common.

Chavicol occurs in betel-leaf oil from Java and in bay oil. Methyl chavicol (estragol) was first found in anise-bark oil and later in estragon oil. Accompanying its isomer, anethol, it occurs in the oils of anise, star-anise, and fennel.

Eugenol is found in considerable amount in oil of cloves and oil of clove stems, in the former also as acetic ester. It appears to be fairly widely distributed, the oils of allspice and bay being rich in this phenol. Commercially it has also been obtained from camphor oil after the camphor had been removed. It is frequently accompanied by its methyl ether, the allyl veratrol, thus, *e. g.*, in bay oil. Its isomer, betel phenol, is the principal constituent of betel-leaf oil.

Safrol, a methylene ether, is the principal constituent of sassafras oil and, like eugenol, has been obtained on a commercial scale from camphor oil. It is also a constituent of cinnamon-leaf oil, star-anise oil, and massoy-bark oil.

Asarone is a constituent of the oil of *Asarum Europæum* and of matico oil.

As derivatives of a tetratomic phenol the isomeric apiols, $C_6H.C_3H_5.O_2CH_2.(OCH_3)_2$, should be mentioned. The common apiol is contained in parsley-seed oil and in Venezuelan camphor-wood oil. Its isomer, the dill apiol, has been found in East Indian dill oil.

b. Of the oxygen derivatives of the olefinic benzene hydrocarbons which have the oxygen in the side chain, cinnamic aldehyde and acid are the principal compounds to be enumerated. The former constitutes a large part of cassia oil, which is valued according to its aldehyde content. It is also an important constituent of cinnamon oil, which, however, contains numerous other substances that render it more valuable than cassia oil. Like benzaldehyde, cinnamic aldehyde is readily oxidized, hence oils containing this aldehyde are apt to contain this acid also, especially when exposed to the air.

In this connection there may also be mentioned the *o*-methoxy cinnamic aldehyde (*o*-cumaric aldehyde methyl ether) found in cassia oil, and cumarin.

Sulphur Derivatives of Hydrocarbons.—Of sulphur compounds corresponding to alcohols, aldehydes, ketones, acids, and esters, none has thus far been found in volatile oils. However, a few compounds corresponding to the ethers have been observed thus far, viz., dimethyl sulphide, $(CH_3)_2S$, in American oil of peppermint; vinyl sulphide, $(C_2H_3)_2S$, in the oil of *Allium ursinum;* allyl sulphide, $(C_3H_5)_2S$, was formerly supposed to be the principal constituent of the oils of garlic and onion. According to Semmler, however, the constituents are a disulphide $C_6H_{12}S_2$ (allyl propyl disulphide = $C_3H_5S.SC_3H_7$), a disulphide $C_6H_{10}S_2$, a trisulphide $C_6H_{10}S_3$, and even higher polysulphides.

When fresh herbs and seeds, rich in albuminous substances, are distilled, the forma-

tion of hydrogen sulphide is not infrequently observed. Small amounts of carbon disulphide have been found in the oil of black mustard.

NITROGEN DERIVATIVES.—Of simple amido compounds, none have been found thus far. Of mixed compounds, *o*-amido benzoic or anthranilic acid has been found recently as methyl ester in oil of orange flowers, in which it plays an important rôle as perfume. Whereas the oil extracted from orange-flower water contains as much as 16 per cent. of this ester, and the commercial oil, which is obtained as a by-product in the distillation of orange-flower water, less than 1 per cent., it becomes apparent that commercial oil of orange flowers should not be used in making orange-flower water.

Of nitriles several are known to occur in oils. Hydrocyanic acid, the nitrile of formic acid, occurs widely distributed in nature in the form of a glucoside (comp. Benzaldehyde). The nitrile of phenyl acetic acid has been found in the oils of *Tropæolum majus* and *Lepidium sativum*, the nitrile of phenyl propionic acid in the oil of *Nasturtium officinale*. Gadamer, however, has shown that these substances are formed only when the material is not treated properly before distillation. These nitriles are decomposition-products due to the action of heat on glucosides contained in the plants. If ferments are allowed to act on these glucosides before distillation, mustard oils result as they do in related plants.

Mixed Sulphur and Nitrogen Compounds.—The mustard oils, the esters of isothiocyanic acid, are obtained from a number of cruciferous plants when properly treated, and are characterized by their extremely pungent odor. The common mustard oil or allyl isosulphocyanate is obtained from *Brassica nigra* and *B. juncea*. It has also been found in the following plants: *Alliaria officinalis, Capsella bursa pastoris, Cardamine officinale, Sisymbrium officinale, Cochlearia armoracia*, and *Thlaspi arvense*. Secondary butyl mustard oil constitutes the principal constituent of oil of spoonwort; *p*-hydroxybenzyl mustard (sinalbin mustard) oil is obtained from the seeds of *Sinapis alba;* phenyl ethyl mustard oil from mignonette root; benzyl mustard oil from *Tropæolum majus* and *Lepidium sativum;* phenyl ethyl mustard oil from *Nasturtium officinale*.

The Examination of Volatile Oils.—The criteria by which oils are most commonly judged are appearance, odor, and taste. The latter qualities are of greatest importance to the perfumer, the confectioner, and manufacturer of liquors. When used as flavoring agents for galenicals, they are equally important to the pharmaceutical manufacturer. The physiological standards by which experts judge oils are, however, difficult of exact description. The standards will also vary with different experts. For this reason physical standards were ascertained and used at an early date in the manufacture and sale of these oils. Among these the specific gravity and solubility test in alcohol have possibly played the more important rôle. With an increasing knowledge of the chemical constituents of the oils, chemical methods have become more prominent.

As a rule no great changes result in the volatile constituents of plants when the latter are transplanted from their native habitat and cultivated. Differences in climate, season, soil, and cultivation, however, do bring about changes, and even different conditions of temperature and humidity will produce qualitative and quantitative changes on the same plantation in different years. As a result of these studies, the limits of constants are now widened, when comparatively few years ago they were being drawn rather sharply.

Besides, skilful adulteration often makes detection absolutely impossible. Thus, no one can detect by chemical or other means the presence of pure, artificial methyl salicylate in oil of wintergreen, or of pure, artificial benzaldehyde in oil of bitter almond. The nose of the expert perfumer may detect a slightly foreign odor in an artificial oil of lemon made by adding citral from a grass oil to washed lemon oil, but such a mixture may defy chemical proof of adulteration.

Nevertheless, both physical and chemical methods, particularly a combination of both, will often enable the detection of practices of gross adulteration. By adulteration is to be understood, not only the addition of inferior or cheaper articles (turpentine or alcohol), but also the withdrawal of some of the more valuable constituents—*e. g.*, menthol from oil of peppermint. Changes in specific gravity may indicate, *e. g.*, the addition of turpentine oil to peppermint oil or the withdrawal of menthol. By chemical means the exact amount of menthol in the oil can be ascertained.

DETERMINATION OF PHYSICAL PROPERTIES.—*Specific Gravity.*—Whereas some manufacturers and jobbers still use the hydrometer, this instrument is scarcely of sufficient

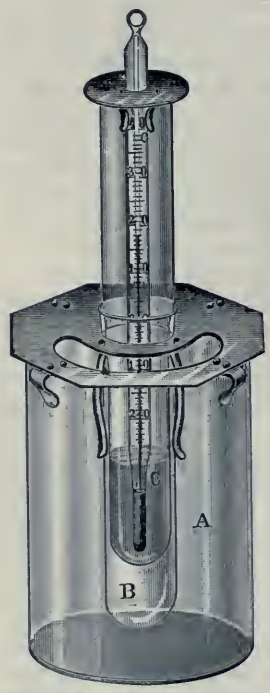
accuracy and requires large amounts of material. For a rapid determination with a very fair degree of accuracy the Mohr-Westphal balance or any of its modifications is to be recommended. For very small quantities and greater accuracy a pycnometer of convenient size and construction should be used.

The specific gravity of oils is mostly recorded at 15° C. (59° F.) with the exception of such oils as congeal entirely or in part at this temperature. For such oils a higher temperature has to be taken. On account of the fact that average room temperature, both in winter and summer, is nearer 25° C. (77° F.) than 15° C. (59° F.), the new edition of the U. S. P. has adopted 25° C. (77° F.) as the standard temperature. The differences in specific gravity of volatile oils due to a difference of 1 degree in temperature are but slight when the weight of a given volume of oil is compared with the weight of a like volume of water at the same temperature. For U. S. P. oils this difference has been determined by O. Schreiner.

Optical Rotation.—The importance of this factor as a means of determining the purity of an oil or the general nature of its adulteration, has been recognized by the new edition of the U. S. P. The data given are usually those for a column of oil 100 mm. in length. Colored oils may necessitate the use of shorter tubes or dilution of the oil with an optically inactive solvent. Inasmuch, however, as the action of the solvent on the oil is not always well understood, its use should be avoided whenever possible. The constants recorded are either α_D, the observed angle of rotation in a 100 mm. tube with sodium light, or $[\alpha]_D$, the specific rotation, calculated from the formula $[\alpha]_D = \frac{\alpha}{l.\,d.}$, where α is the observed angle of rotation, l the length of the tube in millimeters, and d the specific gravity of the oil.

Boiling Temperature.—Inasmuch as the volatile oils are mixtures of substances with different boiling-points, it is improper to refer to their boiling-point. The intervals in temperature between which an oil boils may be designated its boiling temperature. Sometimes it is important to note that the bulk of the oil distils between certain degrees, or that none of it distils below or little above a certain temperature, when other conditions would indicate contamination or withdrawal.

Fig. 287.



Beckmann's apparatus for determining the congealing-point of oils.

Congealing-point.—With certain oils, especially anise, star-anise, fennel, and rue oils, the congealing-point gives a good basis for judging the quality With the first three oils a high congealing-point shows a large content of anethol, with rue oil one of methyl nonyl ketone.

The determination of the congealing-point can be very well performed with Beckmann's well-known apparatus for the determination of molecular weights by the lowering of the freezing-point. A few slight changes make it especially suited for this purpose. These consist principally in discarding the cork connections, which hinder the free inspection of the mercury column of the thermometer. The battery jar *A* serves as the receptacle for the cooling liquid or freezing mixture. The glass tube *B* hanging in the metal cover serves as an air jacket for the freezing-tube *C* and prevents premature congealing of the oil to be tested. The freezing-tube *C* is wider at the top and becomes narrower at the point where it rests on the edge of the tube *B*. In order to retain *C* in a fixed position three glass projections are fastened on the inside of the tube *B*, about 5 Cm. below its upper edge. The thermometer, which is graduated into half degrees, is held in position in a metal plate by three springs which allow of sliding the thermometer up or down.

In conducting the determination with anise and star-anise oil the battery jar is filled with cold water and pieces of ice, but with fennel oil a freezing-mixture of ice and salt is used. Then pour into the freezing-tube so much of the oil to be tested that it stands at a height of about 5 Cm. in the tube and bring the thermometer,

which must not touch the sides of the tube at any place, into the liquid. During the cooling the overcooled oil is to be protected from disturbances, which would produce premature congelation.[1] When the thermometer has sunk about 10 degrees below the congealing-point (with anise and star-anise oil to about 6 to 8 degrees), crystallization is to be induced by rubbing and scratching the thermometer against the sides of the tube. If this proceeding should not prove successful, a small crystal of congealed oil or some solid anethol is brought into the liquid, when congelation will take place with liberation of heat. Solidification is hastened by continued stirring with the thermometer, the mercury column of which rapidly rises and finally reaches a maximum which is called the congealing-point of the oil.

FIG. 288.

Graduated cylinder.

Solubility.—The volatile oils are, as a rule, readily soluble in the common organic solvents, such as alcohol, ether, chloroform, benzene, acetic ether, carbon disulphide, glacial acetic acid, petroleum ether, etc., but for testing purposes 90 per cent., 80 per cent., and 70 per cent. (by volume) alcohol are used almost exclusively, for, although all oils are readily soluble in absolute alcohol, only some of them are entirely soluble in dilute alcohol. For the last class this property becomes a practical and rapid means of examination. The presence of the difficultly soluble turpentine oil can, for instance, be readily shown in this manner in the oils soluble in 70 per cent. alcohol. The solubility determination is very simple.

Bring into a small graduated cylinder (Fig. 288) ½–1 Cc. of the oil to be tested and add small portions of the alcohol at a time until, with vigorous shaking, solution is effected.

If an oil which is soluble under normal conditions does not dissolve, it is sometimes possible to draw conclusions as to the adulterant from the character of the turbidity and the separation of the insoluble part. Petroleum floats on 70 per cent. alcohol, whereas fatty oil settles in drops at the bottom.

Dowzard[2] suggests that the "solubility value" be determined by dissolving 5 Cc. of an oil in 10 Cc. of alcohol, specific gravity 0.799, and diluting with water from a burette until the solution becomes turbid. By multiplying the number of Cc. of water by 100 the "solubility value" is obtained.

Duyk[3] recommends the use of a solution of sodium salicylate in water 1 : 1. The alcohols, aldehydes, and ketones are much more soluble than the sesquiterpene hydrates, phenol ethers and esters. The hydrocarbons are practically insoluble. In special cases this solution may prove valuable.

Chemical Methods of Testing.—The older chemical methods of testing volatile oils, such as the fulminating test with iodine and the various color reactions, have been dropped more and more with a better understanding of the chemical composition of these oils. The application of methods, serviceable in the examination of fatty oils, have mostly proved useless because the analogy between fatty and volatile oils is physical rather than chemical.

Even the following methods, that have proved very serviceable, should be used with such caution as the imperfections of the knowledge of the chemical composition of any particular oil to which they are applied demand.

Saponification.—Through scientific investigation it has been established that many volatile oils contain ester-like compounds, the components of which are alcohols, usually of the composition $C_{10}H_{18}O$ or $C_{10}H_{20}O$, on the one hand, and acid radicals of the fatty series, on the other.

The esters, which are almost without exception of a pleasant odor, are often to be considered as the most important constituents of the oils. Thus, linalyl acetate is the carrier of the odor in bergamot oil. The esters of borneol, found in the different pine-needle oils, play an important part in the formation of the pine aroma. Menthyl acetate is found in the peppermint oils and the geranyl ester of tiglic acid in the different geranium oils. The quantitative estimation of the ester is always valuable for judging the oils, even when the esters are of little consequence to the odor.

[1] A premature congelation often takes place when the oil has not been filtered clear, as suspended dust particles may give rise to congelation.

[3] Bull. de l'Acad. roy. de Méd. de Belgique, 1899, p. 503; Ann. de Pharm., 5, p. 348.

Kremel distinguishes acid number (S. Z.), ester number (E. Z.), and saponification number (V. Z.). The acid number expresses how many milligrammes of KOH are necessary to neutralize the amount of free acid contained in 1 Gm. of oil. The ester number gives the amount of potassium hydroxide in milligrammes used in the saponification of the ester contained in 1 Gm. of oil. The saponification number is the sum of the acid number and the ester number. As the volatile oils usually contain only a small amount of free acid, this factor may in general be neglected. Only old, partly spoiled oils tend to show somewhat higher acid numbers.

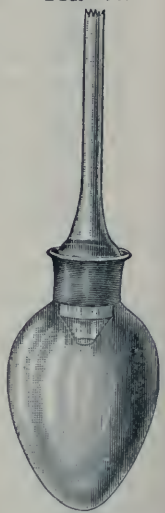
It must be mentioned that in all oils which contain aldehydes the ester determination by saponification cannot be made, as a consumption of alkali takes place which increases with the length of the reaction, due to decomposition of the aldehyde, but which gives no information as to the amount of aldehyde decomposed.

The saponification is conducted in a wide-necked flask of potash glass of 100 Cc. capacity (Fig. 289). A glass tube about 1 meter in length and passing through a stopper serves as a reflux condenser. About 2 Gm. of oil are weighed accurately to within 0.010 Gm. into such a flask and 10 to 20 Cc. of a seminormal alcoholic potassium hydroxide solution are added. Previous to this the oil should be tested for free acid, an alcoholic solution of phenolphtalein being used as indicator. The flask provided with the condensing-tube is heated for half an hour on a steam-bath, and after cooling, the contents are diluted with about 50 Cc. of water and the excess of alkali titrated back with seminormal sulphuric acid.

Fig. 289.

Saponification flask.

Fig. 290.



Acetylization flask.

Acetylization.—Many volatile oils contain as important constituents alcohols of the formulas $C_{10}H_{18}O$ and $C_{10}H_{20}O$; for instance, borneol, geraniol, terpineol, linalool, thujylalcohol, menthol, and citronellol. For the quantitative estimation their behavior toward acetic acid anhydride, with which they form acetic esters when heated, may be used. The reaction takes place according to the equation: $C_{10}H_{18}O + (CH_3CO)_2O = C_{10}H_{17}OCOCH_3 + CH_3COOH$. The reaction is quantitative with borneol, geraniol, and menthol, and makes an accurate determination of these bodies possible. Less favorable are the conditions with linalool and terpineol, as these on boiling with acetic acid anhydride are partly decomposed by splitting off water with the formation of terpenes.

Acetic acid anhydride acts differently on aldehydes. While citronellal is converted quantitatively into isopulegol acetate, with citral there are formed indefinite amounts of saponifiable products as yet unknown.

For the quantitative acetylization 10 to 20 Cc. of the oil, mixed with an equal volume of acetic acid anhydride and 1 to 2 Gm. of dry sodium acetate, are boiled uniformly from 1 to 2 hours in a small flask provided with a condensing-tube which is ground into the neck of the flask (Fig. 290). After cooling, water is added to the contents of the flask and the mixture then heated from $\frac{1}{4}$ to $\frac{1}{2}$ hour on a water-bath, to decompose the excess of the acetic acid anhydride. The oil is then separated in a separating funnel, and washed with sodium hydroxide solution and water until the reaction is neutral. Of the acetylized oil, dried with anhydrous sodium sulphate, 2 Gm. are saponified according to the method described above.

Aldehyde Determination.—The quantitative determination of cinnamic aldehyde depends on its property to form a water-soluble addition-product with an excess of sodium bisulphite. When a known amount of an oil containing cinnamic aldehyde is shaken sufficiently long with a hot concentrated bisulphite solution, the aldehyde content of the oil is about equal to the decrease in volume. Citral behaves similarly to cinnamic aldehyde, and is able to form a water-soluble bisulphite addition-product. The same method, is, therefore, applicable to oils rich in citral, as, for instance, lemongrass oil.

A method devised by Kremers and Schreiner specially for the estimation of carvone will be discussed under Oleum Cari.

Phenol Determination.—For an approximately accurate phenol determination in volatile oils, the property of the phenols to combine with alkalies to form compounds which are soluble in water, is used. If a measured quantity of an oil is shaken with a solution of alkali, the content of phenols can be approximately determined from the diminution in volume. The sodium hydroxide solution should be of 5 per cent. strength. A greater concentration is not allowable, as stronger phenol-alkali solutions take up relatively large amounts of the remaining constituents of the oil, and thus give results which are too high. The technique of such a determination is described under OLEUM THYMI.

According to Thoms (1891), eugenol is quantitatively changed to benzoyl eugenol and weighed as such. This method is especially to be recommended with clove oil and the oil of cinnamon leaves, as shaking out with alkali gives results which are too high. The details of Thoms' method for estimating eugenol may be found in the special works treating of volatile oils and previously referred to.

The Detection of Some of the more common Adulterants.—Turpentine Oil.—Turpentine oil may be considered as the adulterant most often used. Very often it can be recognized by its characteristic odor, especially in those oils which contain no pinene, as this is the main constituent of turpentine oil. In general, its presence causes changes in the specific gravity, solubility, boiling temperature, and optical rotation. It must here be remembered that there are dextrogyrate as well as lævogyrate turpentine oils.

The positive proof of the presence of turpentine oil in oils, which in their pure state contain no pinene, is furnished by the isolation of characteristic derivatives of pinene. The constituents boiling in the neighborhood of 160° C. (320° F.) are fractionated out and the pinene nitrosochloride, as well as pinene nitrolbenzylamine or pinene nitrolpiperidine, is prepared.

If pinene is a normal constituent of the oil, the addition of turpentine oil can be recognized by a comparison of the physical properties of the lowest boiling fractions of the adulterated oil with the corresponding portions of the pure oil.

Cedar Wood, Copaiba, and Gurjun Balsam Oils.—On account of their cheapness and faint odor, these three oils belong to the most favored and the most dangerous of adulterants. They may, however, be detected without difficulty in most cases by means of their physical properties, which differ from those of many of the volatile oils, namely, their difficult solubility in 70 to 90 per cent. or even stronger alcohol, their high specific gravity (above 0.900), their high boiling temperature (above 250° C.), and, finally, their rotatory powers.

All three oils turn the plane of polarized light more or less to the left. With copaiba oil the angle of rotation, α_D, lies between —7° and —35°, with cedar wood oil between —30° and —40°, and with gurjun balsam oil between —35° and —130°.

Alcohol.—The addition of alcohol to a volatile oil always results in a lowering of the specific gravity. When an oil containing alcohol is dropped into water, the drops do not remain clear and transparent, as is the case with pure oils, but become opaque and milky.

For the definite identification of alcohol the suspected oil is heated until it just begins to boil, and the first few drops that come over are collected in a test-tube and filtered, to remove any oil-globules which may also have come over, through a filter moistened with water. The filtrate is made strongly alkaline with dilute potassium hydroxide solution, and treated, after heating to 50°–60° C. (122°–140° F.), with a solution of iodine in potassium iodide until the solution remains slightly yellow. If alcohol be present, small crystals of iodoform will separate in a short time at the bottom of the liquid. It must here be remembered that other bodies, such as aldehydes, acetone, and acetic ether, also yield iodoform under the given conditions.

Larger amounts of alcohol may be removed from volatile oils by shaking with water, from which the alcohol may again be removed by distillation and identified by the iodoform reaction. If the shaking out is done in a graduated cylinder, the increase of the watery layer corresponds approximately to the amount of the alcohol.

According to Hager, it is advantageous to use glycerin, because with this the two layers separate better, and a more accurate reading is possible.

The alcohol content may also be calculated approximately if the specific gravity is determined before and after shaking with water.

Fatty Oil.—The volatile oils adulterated with fatty oil leave a permanent fatty stain when evaporated on paper. With high boiling and difficultly volatile oils, however,

similar residues are left, which may give rise to mistakes. Fatty oil is insoluble in 90 per cent. alcohol.[1] For the separation of the fatty oil from the volatile oil the latter is distilled off by steam distillation or removed by evaporation in an open dish on a water-bath, but it must be remembered that some volatile oils, as bergamot, lemon, orange, anise, and star-anise oil, leave a residue of several per cent. even when they are not adulterated.

The presence of the fat may be shown qualitatively in the residue by heating with potassium bisulphate in a test-tube, Penetrating odors of acrolein show its presence. By igniting the residue on a platinum foil the characteristic odor of burning fat is noticed.

As the fatty oils give saponification numbers which lie between 180 and 200, the amount of the fat added can be determined quantitatively either directly in the volatile oil itself or in the distillation residue, by saponification.

Oils that have been adulterated with cocoanut oil solidify wholly or in part in a freezing-mixture. Cocoanut oil has been found in cananga oil, citronella oil, and palmarosa oil, and detected in this manner.

Mineral Oil, Petroleum.—Mineral oil, paraffin oil, kerosene, petroleum, and petroleum fractions are insoluble in alcohol and can, therefore, be detected without difficulty in volatile oils; besides, they are often easily recognized by their low specific gravity. Palmarosa oil to which some mineral oil has been added is only partly soluble in 70 per cent. alcohol. If the insoluble portion is successively treated with 90 per cent. and absolute alcohol, an oil remains, which in the beginning, it is true, is colored brown by sulphuric or nitric acid, but in general resists the action of these acids and also of alkalies, and on saponification with alcoholic solution of potassium hydroxide gives no saponification number.

The mineral oils have different boiling-points. The hydrocarbons of illuminating oil boil at about the same temperature as the terpenes. Lower boiling fractions are said to be sometimes used for adulterating turpentine oil. A higher boiling mineral oil, about 250° C. (482° F.), has been found in citronella and in gingergrass oils. The petroleum fractions of a lower boiling-point are easily volatile with water vapor, the higher fractions not at all, or at least to a small degree only.

A method for the quantitative estimation of mineral oils consists in weighing the residue left after having removed the volatile oil by oxidation with fuming nitric acid, as described under OLEUM TEREBINTHINÆ (which see). Attention should be called to the fact that some volatile oils, such as rose oil, chamomile oil, orange-flower oil, and others, contain larger or smaller amounts of paraffins as natural constituents.

Chloroform.—This body, which has been found occasionally in volatile oils (for instance, in cognac oil and sandalwood oil), can be isolated by distillation on a water-bath and identified by the isonitrile reaction. This consists in treating a small amount of the suspected distillate with a few drops of aniline and alcoholic sodium hydroxide solution, and gently heating. In the presence of chloroform the noxious and exceedingly disagreeable smelling vapors of phenylisonitrile are formed.

OLEATA.—Oleates.

Oléates, Oléés, Fr.; *Oleate*, G.

This class of preparations was first proposed by Lhermite (*Jour. Phar. Chimie*, Oct., 1854, p. 301), but did not attract attention until recommended by Prof. John Marshall (1872). They are combinations of oleic acid with metallic bases or alkaloids, but as medicinally employed they are usually mixtures of the true or normal oleates with oleic acid, olive oil, lard, or some other diluent. In the case of the alkaloids the respective oleates are prepared by direct solution in oleic acid, to facilitate which a moderate degree of heat may be employed. The U. S. P. defines the official alkaloidal oleates as solutions of the respective alkaloids in oleic acid in excess, and containing, except in the case of quinine oleate, about 50 per cent. of olive oil as a diluent. In the case of metallic oleates, however, mutual decomposition is frequently resorted to, for which purpose either a specially prepared sodium or potassium oleate is employed, or a solution of castile soap, which latter, being a sodium oleo-palmitate, will of course yield also an impure oleate; but for all practical purposes this slight impurity may generally be disregarded, particularly in the case of lead, zinc, and copper. The proportion of alkaloid or metallic oxide to be dissolved in oleic acid may vary to suit the particular views of the practi-

[1] Only castor oil is soluble in 90 per cent., but is insoluble in 70 per cent. alcohol.

tioner, but since the union of oleic acid with the base results in a definite chemical compound, the limit set by nature cannot be exceeded; this limit represents the following proportions of base represented by normal oleates, calculated for anhydrous alkaloids and metallic oxides, respectively: aconitine 69.57 per cent., atropine 50.6 per cent. cocaine 51.8 per cent., morphine 50.3 per cent., quinine 53.46 per cent., strychnine 54.22 per cent., bismuth 22.2 per cent., copper 12.7 per cent., lead 29 per cent., iron (ferric) 8.9 per cent., mercury (mercuric) 28.4 per cent., zinc 12.9 per cent. The solutions of alkaloidal oleates are usually made of the strength of 2 per cent., except morphine and cocaine (usually 5 per cent.) and quinine (25 per cent.). In the case of metallic oleates the use to which they are to be put must be considered in the choice of proper diluents; for mercuric oleates and all those intended for endermatic medication only oleic acid should be employed, as it is more readily absorbed than fats and solid hydrocarbons; for those oleates intended for use in skin diseases, petrolatum or benzoinated lard may be used. The more nearly oleic acid is saturated with mercuric oxide the better will the preparation keep, and hence either the normal or the official oleate should be kept in stock for dilution as wanted, the necessary oleic acid being readily incorporated. 10 parts of normal mercuric oleate diluted with 18.4 parts of oleic acid will produce the 10 per cent. oleate, and if diluted with 46.8 parts of acid the 5 per cent. oleate will be obtained.

Although a solution of castile soap has been strongly recommended for the preparation of normal metallic oleates, a purer product can be obtained by using sodium or potassium oleate prepared direct from oleic acid, as follows: Warm in a capacious vessel 2000 grains of purified oleic acid (U. S. P. 1900) to about 60° or 66° C. (140°–150.8° F.), and add slowly a solution of 316 grains of sodium hydroxide, or 443 grains of potassium hydroxide (U. S. 90 per cent.), in a mixture of 1½ fluidounces of alcohol and 4 ounces of water, stirring constantly until the acid is neutralized, and a small portion of the resulting soap dissolved in alcohol yields but a faint pink tint on the addition of a few drops of alcoholic solution of phenolphtalein. The soap is then dissolved in 6 pints of warm water and filtered; this neutral solution may be used for the decomposition of metallic salts, and will yield very satisfactory normal oleates; for instance, to the above quantity (6 pints) may be added, slowly and with constant stirring, a warm solution of 884 grains of cupric sulphate in 2 pints of water, or of 1350 grains of pure lead acetate in 4 pints of warm water, etc. More extended information, together with working formulas for the various oleates, will be found in the *Amer. Jour. Pharm.* for 1881 and 1889, and *Drugg. Circ.*, 1885.

Ointments of the Oleates.—Manufacturers have for some time offered a class of preparations under the name of ointments of the various oleates, in regard to which some confusion exists, since the base used by different manufacturers varies, as well as the proportion of oleate; physicians may therefore find these ointments of varying composition and consistence, as either benzoinated lard or petrolatum (soft or hard) has been used in their preparation. The term "ointment of any oleate, 5 or 10 per cent." can have but one meaning as far as the active ingredient is concerned—namely, that the finished product contains 5 or 10 parts of the respective normal oleates in every 100 parts of the ointment, and not 5 or 10 parts of the alkaloid or metallic oxide, as is frequently supposed; this, of course, makes a considerable difference in the strength of the oleate ointments, and should be borne in mind whenever they are prescribed. Ointments of oleates are recognized as such in one instance in the U. S. P. and in two instances in the Br. P., ointment of zinc oleate being official in both pharmacopœias, and ointment of mercuric oleate only in the British, although the ointments of aconitine, atropine, cocaine, and veratrine of the latter pharmacopœia are also ointments of the respective alkaloidal oleates, since the alkaloids are directed to be dissolved in oleic acid and then mixed with lard. Physicians may save themselves and pharmacists much annoyance when prescribing ointments of oleates, by designating the amount of oleate (normal or of a stated percentage strength), as well as the kind of vehicle (lard or petrolatum) to be used, or by specifying the name of the manufacturer whose product they may desire.

OLEATUM ATROPINÆ, *U. S.*—Oleate of Atropine.

Atropinum oleicum.—Oléate d'atropine, Fr.; *Atropinoleat*, G.

Preparation.—Atropine, 2 Gm.; alcohol, 2 Cc.; oleic acid, 50 Gm.; olive oil, sufficient to make 100 Gm. Triturate the atropine in a tared mortar with the alcohol, then add about an equal quantity of oleic acid and, after warming the water, stir until the

alcohol has evaporated, add the remainder of the oleic acid, and continue stirring until the atropine is dissolved; then add sufficient olive oil to make the product weigh 100 Gm.—U. S.

The use of alcohol, no doubt added to facilitate solution of the alkaloid in the oleic acid, seems to us quite unnecessary, since solution can be readily effected without this addition by application of moderate heat. Since each minim of this 2 per cent. oleate weighs about $\frac{4}{5}$ grain, 100 grains of it will measure about 2 fluidrachms.

Action and Uses.—Oleate of atropine may be locally employed for its anodyne properties. (See BELLADONNA.)

Allied Preparations.—OLEATE OF ACONITINE, OLEATE OF MORPHINE, and OLEATE OF STRYCHNINE may be prepared in exactly the same manner as oleate of atropine. If a higher percentage strength is desired, which is sometimes the case with oleate of morphine, it is only necessary to increase the amount of alkaloid to correspond to the percentage indicated.

OLEATUM COCAINÆ, *U. S.*—Oleate of Cocaine.

Cocainum oleicum.—Oléate de cocaine, Fr.; *Cocainoleat*, G.

Preparation.—Cocaine, 5 Gm.; alcohol, 5 Cc.; oleic acid, 50 Gm.; olive oil, sufficient to make 100 Gm. Triturate the cocaine in a tared mortar with the alcohol, then add about an equal volume of the oleic acid, and, after warming the mortar, stir until the alcohol has evaporated, add the remainder of the oleic acid, and continue stirring until the cocaine is dissolved; then add sufficient olive oil to make the product weigh 100 Gm.—U. S.

Cocaine alkaloid dissolves readily in warm oleic acid, and hence heating the alkaloid with the acid in a small dish on a water-bath, without the alcohol, will produce satisfactory results. A fluidounce of this 5 per cent. oleate weighs 423 grains. 100 grains of it will therefore measure very nearly 2 fluidrachms.

Action and Uses.—This solution may be employed in the eye and urethra as a local anæsthetic. (See COCA.)

OLEATUM HYDRARGYRI, *U. S.*—Oleate of Mercury.

Hydrargyri oleas, Br.; *Hydrargyrum oleicum.—Mercuric oleate*, E.; *Oléate mercurique*, Fr.; *Quecksilberoleat, Mercurioleat*, G.

Preparation.—Yellow mercuric oxide, in very fine powder, 25 Gm.; distilled water, 25 Cc.; oleic acid, 70 Gm. or sufficient to make 100 Gm. Triturate the yellow mercuric oxide with the distilled water in a tared mortar; add the oleic acid, and mix thoroughly; warm the mortar (not exceeding 50° C.), stir occasionally until the water has evaporated, then add, if necessary, oleic acid to make 100 Gm. and mix thoroughly. Avoid contact with metallic utensils; preserve the oleate in tightly stoppered wide-mouth bottles.—U. S.

To prepare 1 avoirdupois ounce of the official mercuric oleate, use 110 grains each of yellow mercuric oxide and distilled water, and 330 grains of oleic acid, and proceed as directed above.

Take of mercuric chloride, 1 ounce; powdered hard soap, 2 ounces; oleic acid, 1 fluidrachm; boiling distilled water, a sufficient quantity. Dissolve the mercuric chloride in 10 ounces of the distilled water. Triturate the oleic acid with the hard soap, and dissolve the product in 11 ounces of the distilled water. Mix the solutions; boil for 10 minutes; set aside for the mercuric oleate to deposit; decant the supernatant liquid; wash the precipitated oleate with hot distilled water until the decanted liquid affords little or no reaction for chloride, and then dry it on a water-bath.—Br.

The U. S. preparation constitutes what is commonly called a 25 per cent. oleate, referring to the proportion of mercuric oxide present as oleate. The amount of true mercuric oleate contained in the finished product amounts to 88.25 per cent., the remainder being oleic acid with traces of water. It is of firm butter consistence and has a yellowish color; when made by mutual decomposition between potassium oleate and mercuric nitrate, as first suggested by Louis Dohme in 1873, it is of a pale-cream color. The mercuric oleate of the Br. P. is the normal oleate, having the formula $Hg(C_{18}H_{33}O_2)_2$, mixed with a very small proportion of mercuric palmitate, since the soap used is not pure sodium oleate, but an oleopalmitate. The grayish-yellow color of the British

preparation is no doubt due to partial reduction caused by the heat employed, as precipitated mercuric oleate, made without heat, has a cream color or at most a yellow tint. The object of adding oleic acid to the soap is to prevent the presence of free alkali, caused by hydrolysis of the soap when brought into solution.

Mercuric oleate is readily decomposed at temperatures above 50° C. (122° F.), but keeps well for a long time in a cool place if protected against light and air. Metallic spatulas should never be used in preparing or dispensing mercuric oleate, and only glass or porcelain utensils be employed.

The so-called 5, 10, or 20 per cent. oleates of mercury can be readily prepared from the official (U. S. P.) oleate by diluting the same with oleic acid as follows: 1 part of official oleate with 4 parts of oleic acid to make the 5 per cent., 1 part of the official oleate with 1½ parts of oleic acid to make the 10 per cent., and 1 part of the official oleate with ¼ part of oleic acid to make the 20 per cent.

Action and Uses.—Oleate of mercury may be employed for the same purposes as UNGUENTUM HYDRARGYRI (which see). When employed by inunction, it is thought by some to be more effective, as it is absorbed with greater rapidity. Its principal use is in the treatment of hereditary syphilis, indurations following abscesses, and chronic skin diseases. The amount employed for the treatment of syphilis in children is from 10 to 15 grains (0.60–1 Gm.), twice daily for several days.

OLEATUM QUININÆ, *U. S.*—Oleate of Quinine.

Chininum oleicum.—Oléate de quinine, Fr.; *Chininoleat*, G.

Preparation.—Quinine, 25 Gm.; oleic acid, sufficient to make 100 Gm. Triturate the quinine in a warm water with a small quantity of the oleic acid to a smooth paste. Then add the remainder of the oleic acid, previously warmed, and stir frequently until the quinine is dissolved.—U. S.

The solution of quinine alkaloid can be readily effected by triturating the same with about twice its weight of oleic acid in a porcelain capsule on a water-bath, using a thick glass rod as a stirrer. A fluidounce of the above (25 per cent.) oleate weighs about 410 grains, and therefore contains about 102 grains of quinine alkaloid, or 163.5 grains of quinine oleate, which is equivalent to about 140 grains of the ordinary quinine sulphate.

Action and Uses.—Oleate of quinine may be employed both internally and externally. For its uses see QUININA.

OLEATUM VERATRINÆ, *U. S.*—Oleate of Veratrine.

Veratrinum oleicum. Oléate de veratrine, Fr.; *Veratrinoleat*, G.

Preparation.—Veratrine, 2 Gm.; oleic acid, 50 Gm.; olive oil, sufficient to make 100 Gm. Triturate the veratrine in a tared mortar with about 5 Cc. of olive oil, and, after warming the mortar, add the oleic acid, and continue stirring until the veratrine is dissolved; then add sufficient olive oil to make the product weigh 100 Gm.—U. S.

Since each minim of this 2 per cent. oleate weighs about ⅘ grain, 100 grains of it will measure about 2 fluidrachms.

Action and Uses.—Oleate of veratrine may be locally employed for the relief of superficial neuralgias. Care should be taken not to apply it over too large an area or to an abraded surface, lest absorption of the drug take place.

OLEATUM ZINCI.—Oleate of Zinc.

Zincum oleicum. Oléate de zinc, Fr.; *Zinkoleat*, G.

Preparation.—Make 6 pints of neutral soap solution from pure oleic acid and sodium hydroxide (see page 1047), warm to 43° C. (109.4° F.), and to it add slowly a solution of 1100 grains of zinc sulphate in 2 pints of water, stirring constantly; collect the precipitate on a moist filter, wash thoroughly with water, and dry on bibulous paper at a temperature not exceeding 38° C. (100° F.). It is important that the temperature during precipitation be maintained between 38° and 43° C. (100°–110° F.), so that the

oleate when dry may be obtained in white friable masses which can easily be passed through a hair-cloth sieve. Oleate of zinc is an impalpable, unctuous, slippery powder, with slight saponaceous odor, which upon exposure to air gradually becomes offensive. It should be preserved in tightly stoppered bottles in a cool place.

The above formula was first suggested by Geo. M. Beringer, and in our experience yields a satisfactory product.

Action and Uses.—Oleate of zinc is intended to be mixed with some ointment-base and applied externally. The impalpable powder, which is largely used, may be employed locally in the treatment of chronic skin affections.

OLEORESINÆ.—Oleoresins.

Oléo-résines, Extraits éthérés, Fr.; *Oelharze, Aetherische Extrakte*, G.

These preparations consist mainly of fixed or volatile oils associated with resin and some other constituents, and are directed to be prepared by exhausting the powdered drug with acetone. The great volatility of this solvent renders it necessary to percolate in a well-closed apparatus, in which the pressure is equalized by connecting the receiving vessel with the top of the percolator by means of a tube. The tincture is afterward transferred to a suitable still, and the acetone distilled off on a water-bath with a moderate heat. Various apparatuses have been constructed to accomplish the exhaustion with the smallest possible quantity of acetone by using the same liquid over again until the material has been exhausted; for this purpose the recipient is placed in water of about 70° C. (158° F.); the acetone vapors ascending through the connecting tube mentioned above are condensed in a suitable refrigerator, and the acetone is again passed into the percolator, the operation being repeated as often as required.

Formerly oleoresins were prepared altogether by extracting the drug with ether, but, as pointed out by Beringer in 1892, acetone is an equally good solvent and yields products which are completely soluble in ether. Acetone can now be had of great purity (99.5 per cent.) at a cost considerably below that of pure ether, and as its boiling-point is at least 18° or 20° C. above that of ether, it has been wisely selected by the Pharmacopœia to replace the more volatile solvent. Our experience in the use of acetone for making the official oleoresins has been very satisfactory.

The usual directions for the preparation of oleoresins are to continue percolation of the drug to complete exhaustion, but, as pointed out by Procter nearly 40 years ago, the first portions of percolate contain practically the whole of the oleoresinous constituents, and hence 2 Cc. of percolate for each Gm. of drug operated upon would appear sufficient: in the case of capsicum even less (1.5 Cc.) has been found advantageous, in order to avoid the extraction of large quantities of fat.

OLEORESINA ASPIDII, *U. S.*—Oleoresin of Aspidium.

Oleoresina filicis, Extractum filicis liquidum, Br.; *Extractum filicis*, P. G.; *Oleum filicis maris.—Oleoresin or Liquid extract of male fern*, E.; *Extrait éthéré (Huile) de fougère mâle*, Fr.; *Wurmfarnextrakt, Wurmfarnöl*, G.

Preparation.—Aspidium, recently reduced to a No. 40 powder, 500 Gm.; acetone, a sufficient quantity. Put the aspidium into a cylindrical glass percolator, provided with a stopcock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug firmly, and percolate slowly with acetone, added in successive portions, until the drug is exhausted. Recover the greater part of the acetone from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, allow the remaining acetone to evaporate spontaneously. Keep the oleoresin in a well-stoppered bottle.

Note.—Oleoresin of aspidium usually deposits, on standing, a granular-crystalline substance. This should be thoroughly mixed with the liquid portion before use.—*U. S.*

The processes of the other pharmacopœias are essentially identical with the above, except that ether is used as a menstruum and that maceration, instead of percolation, is directed by the P. G. It should be remembered that only that portion of the rhizome is to be used which has still a greenish color; the oleoresin will then have a greenish or brownish-green color, while the entire rhizome with the stipes yields a brown preparation, which not infrequently forms a jelly, probably from the separation of pectin compounds.

The official oleoresin separates a granular deposit of filicic acid, which must be well mixed with the liquid portion on dispensing. The yield is about 10 to 15 per cent.

The oleoresin, well stirred and diluted with glycerin, should not show any starch-granules when examined under the microscope.—P. G.

Action and Uses.—Oleoresin of male fern is largely employed for the expulsion of the tapeworm. It may produce nausea, vomiting, and severe griping; but as a rule usually operates without producing these untoward effects. The patient should not partake of any food for at least 12 hours, and the bowels should be thoroughly evacuated before its administration. The dose is from 1 to 2 fluidrachms (4–8 Cc.), best administered in capsules in divided doses every 15 minutes. This may be followed in 3 or 4 hours by a saline purge. Castor oil should not be given, as it may aid in the absorption of the oleoresin.

OLEORESINA CAPSICI, *U. S.*—Oleoresin of Capsicum.

Oléorésine (Extrait éthérée) de capsique, Fr.; *Spanischpfeffer-Oelharz, Aetherisches Spanischpfeffer-extrakt*, G.

Preparation.—Capsicum, in No. 40 powder, 500 Gm.; acetone, a sufficient quantity. Put the capsicum into a cylindrical glass percolator, provided with a stopcock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug firmly, and percolate slowly with acetone, added in successive portions, until the drug is exhausted. Recover the greater part of the acetone from the percolate by distillation on a water-bath, and having transferred the residue to a capsule, allow the remaining acetone to evaporate spontaneously. Now pour off the liquid portion, transfer the remainder to a strainer, and when the separated fatty matter (which is to be rejected) has been completely drained, mix the liquid portions together. Keep the oleoresin in a well-stoppered bottle.—U. S.

Oleoresin of capsicum is a dark brown-red rather thick liquid, separating on standing a granular deposit of fat. The average yield is about 12 per cent., but as much as 15 per cent. has been obtained. The oleoresin has little odor, but possesses an extremely hot and fiery taste.

Action and Uses.—Oleoresin of capsicum may be locally employed as an ingredient of a plaster or liniment for the purpose of producing counterirritation. Internally it may be added to other remedies to aid in their absorption in cases of gastric atony and flatulence. The dose is from $\frac{1}{4}$ to 1 minim (0.015–0.05 Cc.), best administered in pill-form.

OLEORESINA CUBEBÆ, *U. S.*—Oleoresin of Cubeb.

Extractum cubebarum, P. G.; *Extractum cubebæ œthereum.—Oléorésine de cubébe*, Fr.; *Kubebenextrakt*, G.

Preparation.—Cubeb, in No. 30 powder, 500 Gm.; alcohol, a sufficient quantity. Put the cubeb into a cylindrical glass percolator, pack the powder firmly, and percolate slowly with alcohol, added in successive portions, until the cubeb is exhausted. Recover the greater part of the alcohol from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, allow the remaining alcohol to evaporate, with constant stirring, in a warm place. Keep the product in a well-stoppered bottle.

Note.—Oleoresin of cubeb deposits, after standing for some time, a waxy and crystalline matter, which should be rejected, only the liquid portion being used.—U. S.

The use of alcohol in place of acetone or ether for the manufacture of oleoresin of cubeb was first suggested by the late E. R. Squibb, and has been found to exhaust the drug completely and to yield an entirely satisfactory preparation.

The oleoresin, as prepared by the above formula, is of a brown-green, or sometimes of a grass-green, color, the difference being due to the presence of more or less chlorophyll. On standing, it deposits some waxy matter and cubebin, which are removed by decantation. The remaining liquid, amounting to between 18 and 25 per cent. of the cubebs used, consists mainly of fixed and volatile oils, the active resins, and chlorophyll.

Action and Uses.—This preparation is employed for its action upon the genito-urinary and respiratory tracts. It may be used with advantage in the later stages of gonorrhœa and in subacute and chronic bronchitis. The dose is from 2 to 20 minims (0.10–1.3 Cc.), 3 times daily. It may be given either in emulsion or capsule.

OLEORESINA LUPULINI, *U. S.*—Oleoresin of Lupulin.

Oleoresina lupulinæ, Extractum lupulini æthereum.—Oléorésine de lupuline, Fr.; *Aetherisches Lupulinextrakt*, G.

Preparation.—Lupulin, 100 Gm.; acetone, a sufficient quantity. Put the lupulin into a cylindrical glass percolator, provided with a stopcock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug *very lightly*, and percolate slowly with acetone, added in successive portions, until the drug is exhausted. Recover the greater part of the acetone from the percolate by distillation on a water-bath, and, having transferred the residue to a capsule, allow the remaining acetone to evaporate spontaneously. Keep the oleoresin in a well-stoppered bottle.—U. S.

The yield is variable, often amounting to 50 or 60 per cent. It is of a dark reddish-brown color and semifluid in consistence, and has the odor and taste of the drug.

Action and Uses.—Oleoresin of lupulin is said to possess all the medicinal properties of Humulus (which see). It is usually administered in pill or capsule in doses of from 10 to 30 grains (0.6–2 Gm.).

OLEORESINA PIPERIS, *U. S.*—Oleoresin of Pepper.

Oléorésine de poivre noir, Fr.; *Aetherisches Pfefferextrakt*, G.

Preparation.—Pepper, in No. 40 powder, 500 Gm.; acetone, a sufficient quantity. Put the pepper into a cylindrical glass percolator, provided with a stopcock, and arranged with a cover and receptacle for volatile liquids. Press the drug firmly, and percolate slowly with acetone, added in successive portions, until the drug is exhausted. Recover the greater part of the acetone from the percolate by evaporation on a water-bath, and, having transferred the residue to a capsule, set this aside until the remaining acetone has evaporated, and the deposition of crystals of piperin has ceased. Lastly, separate the oleoresin from the piperin by expression through a muslin strainer. Keep the oleoresin in a well-stoppered bottle.—U. S.

The official process yields from 5 to 6.5 per cent. of a greenish-black oleoresin, consisting of a mixture of volatile and fixed oil holding the pungent resin and some piperin in solution. It is an official substitute for the so-called *oil of black pepper*, which is obtained as a by-product in the manufacture of piperin, and has essentially the same composition, except that the volatile oil is present in small quantities only.

Action and Uses.—Oleoresin of black pepper represents almost entirely the activity of the fruit from which it is prepared. It contains only a small quantity of piperin, but this substance is thought by many to be inert when pure. The oleoresin is to be preferred as a remedy because of its uniform strength. The dose is from $\frac{1}{4}$ to 1 minim (0.015–0.05 Cc.), best administered in pill form.

OLEORESINA ZINGIBERIS, *U. S.*—Oleoresin of Ginger.

Extractum zingiberis æthereum.—Oléorésine (Piperoide) de gingembre, Fr.; *Zingiberin, Aetherisches Ingwerextrakt*, G.

Preparation.—Ginger, in No. 60 powder, 500 Gm.; acetone, a sufficient quantity. Put the ginger into a cylindrical glass percolator, provided with a stopcock, and arranged with cover and receptacle suitable for volatile liquids. Press the drug firmly, and percolate slowly with acetone, added in successive portions, until the drug is exhausted. Recover the greater part of the acetone from the percolate by distillation on a water-bath, and having transferred the residue to a capsule, allow the remaining acetone to evaporate spontaneously. Keep the oleoresin in a well-stoppered bottle.—U. S.

Coated ginger yields between 8 and 12 per cent., and the uncoated (Jamaica) ginger between 6 and 10 per cent. of oleoresin, which, as prepared from the latter, is lighter in color, rather more limpid, and perhaps more agreeable in flavor. The appellation *piperoid* originated with Beral.

Action and Uses.—Oleoresin of ginger may be employed in medicine for the same purposes as the powdered drug (see Zingiber). The dose is from $\frac{1}{4}$ to 1 minim (0.015–0.05 Cc.).

OLEUM ADIPIS, *U. S.*—Lard Oil.

Huile de graisse, Fr.; *Schmalzöl, Specköl*, G.

A fixed oil expressed from lard at a low temperature.

Preparation.—Lard, enclosed in strong canvas bags, is kept for some time near the freezing-point of water, and then subjected to a gradually increased pressure. About 60 or 62 per cent. of oil is obtained.

Properties and Tests.—Lard oil is a colorless or pale-yellow oily liquid, having a peculiar, slightly fatty, odor and a bland taste. Its specific gravity ranges from 0.910 to 0.920 at 15° C. (59° F.) or from 0.905 to 0.915 at 25° C. (77° F.), depending somewhat on the temperature at which the oil has been expressed. It is almost insoluble in cold alcohol and only slightly soluble in boiling alcohol, but is readily soluble in chloroform, ether, carbon disulphide, and benzene. At a temperature a little below 10° C. (50° F.) it usually commences to deposit a white, peculiar fat, and at or near 0° C. (32° F.) it forms a solid white mass. If 5 Cc. of the oil be thoroughly shaken in a test-tube with 5 Cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 Cc. of deodorized alcohol, and adding 2 drops of nitric acid), and the mixture heated for about 5 minutes on a water-bath, the oil should remain nearly or quite colorless, not acquiring a reddish or brown color (absence of more than 5 per cent. of cottonseed oil). The oil should be completely saponifiable with alcoholic potassium hydroxide solution, and the resulting soap should be completely soluble in water, without separation of an oily layer (absence of mineral oils). If 2 Cc. of lard oil be mixed in a test-tube with 2 Cc. of equal volumes of amyl alcohol and carbon disulphide containing 1 per cent. of sulphur in solution, and the test-tube be immersed to $\frac{1}{3}$ or $\frac{1}{2}$ of its depth in boiling salt water, no reddish color should develop in from 10 to 15 minutes (absence of cottonseed oil or of certain other fats). Lard oil saponified by alcoholic potassium hydroxide test-solution should show a saponification value of 195–197. If 0.3 Gm. of lard oil be dissolved in 10 Cc. of chloroform and placed in a 250 Cc. flask with 25 Cc. of a mixture of equal parts of alcoholic iodine test-solution and alcoholic mercuric chloride test-solution, and after standing for 4 hours protected from the light, 20 Cc. of potassium iodide test-solution be added, and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate solution, an iodine figure of not less than 56 nor more than 74 should be obtained.—U. S.

When brought in contact with concentrated sulphuric acid (oil, 50 Gm.; acid, 10 Cc.), a dark reddish-brown color is instantly produced, and the temperature of the mixture rises 47 degrees C. (116 degrees F.).

Uses.—This is a bland oil practically never employed in medicine. It is used as an illuminating oil and in the manufacture of pharmaceutical preparations.

OLEUM ÆTHEREUM, *U. S.*—Ethereal Oil.

Ethereal oil is a volatile liquid consisting of equal volumes of heavy oil of wine and ether.—U. S.

Preparation.—Alcohol, 1000 Cc.; sulphuric acid, 1000 Cc.; distilled water, 25 Cc.; ether, a sufficient quantity. Add the acid slowly to the alcohol, mix them thoroughly, and allow the mixture to stand in a closed flask for 24 hours; then pour the clear liquid into a tubulated retort of such capacity that the mixture shall nearly fill it. Insert a thermometer through the tubulure so that the bulb shall be deeply immersed in the liquid, and having connected the retort with a well-cooled condenser, and also having connected with the receiver a bent glass tube for conducting the uncondensed gases into water, distil, by means of a sand-bath, at a temperature between 150° and 160° C. (302° and 320° F.), until the liquid ceases to come over or until a black froth begins to rise in the retort. Separate the yellow ethereal liquid from the distillate, and expose it to the air for 24 hours in a shallow capsule. Then transfer it to a wet filter, and, when the watery portion has drained off, wash the oil which is left on the filter with the distilled water, which should be as cold as possible. When this also has drained off, transfer the oil to a graduated measure, and add to it an equal volume of ether.—U. S.

Properties and Tests.—Ethereal oil should be transparent and nearly colorless. It has the peculiar, aromatic, ethereal odor of heavy oil of wine, and should be neutral

to litmus. Although heavy oil of wine, when freshly prepared, is neutral, it is reputed to become acid on standing. The specific gravity of ethereal oil is required to be 0.905 at 25° C. (77° F.); the heavy oil of wine, prepared according to official directions, having a specific gravity varying between 1.15 and 1.47.

Composition.—Heavy oil of wine, prepared as above directed, contains 44 to 48 per cent. of ester calculated as diethyl sulphate. Ethereal oil should therefore contain about one-half as much. Of the other constituents we have no satisfactory knowledge.

Ethereal oil is not a volatile oil as its name would indicate, but an artificial product. It serves as an ingredient of Compound Spirit of Ether. The only commercial article that apparently corresponds to the pharmacopœial product is that of the manufacturer who is reported to have supplied the process to the Revision Committee. Inasmuch as this article is stated to give satisfaction therapeutically, and since modifications in the process appear to result in changes in the product which are but little understood, about the only comment that can be passed on this article is to prepare it strictly in accordance with the directions of the Pharmacopœia.

While the assay of ethereal oil based on its ethyl sulphate content will guard against the substitution of cognac oil, it may not exclude preparations to which ethylsulphuric acid has been added.

Action and Uses.—In moderate doses ethereal oil acts as a circulatory stimulant increasing the heart's action and raising blood-pressure. Overdoses depress the heart and the muscular coats of the bloodvessels. This remedy is only employed as an ingredient in the compound spirit of ether, and it is thought to increase the activity and to be less fleeting in its action than a mixture of alcohol and ether.

OLEUM AMYGDALÆ AMARÆ, *U. S.*—Oil of Bitter Almond.

Oleum amygdalæ volatile; Oleum amygdalarum æthereum.—Volatile oil of almond, E.; *Essence d'amandes amères*, Fr.; *Bittermandelöl*, G.

A volatile oil obtained from bitter almond and other seeds containing amygdalin, yielding, when assayed as directed below, not less than 85 per cent. of benzaldehyde, and not less than 2 per cent. nor more than 4 per cent. of hydrocyanic acid. It should be kept in small, well-stoppered, amber-colored, completely filled bottles, protected from light and air.—U. S.

The designation oil of bitter almond was formerly restricted to the volatile products obtained by steam distillation after the hydrolysis of the glucoside amygdalin originally found in the bitter almond *Prunus amygdalus* var. *amara*. With the introduction of other rosaceous seeds, containing sufficient amygdalin, into commerce, the source of the commercial oil has not been restricted to the bitter almond. The seed of the peach, *Prunus Persica* Stokes, and especially those of the apricot, *Prunus Armeniaca* L., which enter the European market from Asia Minor as "peach kernels," yield much of the commercial oil. Few manufacturers distinguish between the oils from the several sources. The same name is also extensively applied to commercial benzaldehyde made from toluene.

The designation "artificial" bitter almond oil having formerly been applied to nitrobenzene, $C_6H_5NO_2$ (oil of mirbane), which has in common with benzaldehyde, C_6H_5CHO, only a crude resemblance in odor, the designation artificial is mostly avoided in connection with benzaldehyde from toluene, the *oleum amygdalarum æthereum sine acido prussico*. This was formerly prepared from the crude oil by the removal of the hydrocyanic acid by means of milk of lime and a ferrous salt.

Preparation and Composition.—Previous to the distillation of the volatile oil the seeds must be deprived of their fatty oil. They are ground to a coarse powder and the oil is expressed by means of hydraulic presses, a pressure of 350 atmospheres being applied. Upon cold expression, bitter almonds yield about 50 per cent., apricot seeds about 25–38 per cent. fatty oil.

The press-cakes are finely ground and are then ready for the manufacture of the volatile oil. This is not present as such in the seeds, but is formed by a process of fermentation similar to that producing mustard oil and oil of wintergreen. In the presence of water, the glucoside amygdalin which is contained in these seeds is decomposed by a ferment known as emulsin into benzaldehyde, hydrocyanic acid, and dextrose, according

to the following equation: $C_{20}H_{27}NO_{11}$ (amygdalin) + $2H_2O$ (water) = C_6H_5CHO (benzaldehyde) + CNH (hydrocyanic acid) + $2C_6H_{12}O_6$ (dextrose).

Inasmuch as the emulsin coagulates at the boiling temperature of water, and thereby loses its activity, the fermentation must be completed before the distillation is begun. The powder is, therefore, mixed with 6–8 parts of water of about 50°–60° C. (122°–140° F.) and the mixture set aside for about 12 hours. The oil formed is then distilled over with water vapor.

Properties.—Oil of bitter almond is a clear or yellowish, thin, and strongly refractive liquid, having a peculiar aromatic odor, and a bitter, burning taste. Specific gravity 1.045 to 1.060 at 25° C. (77° F.). Boiling-point about 180° C. (356° F.). Optically inactive. Soluble in 300 parts of water at 25° C. (77° F.), and in alcohol or ether in all proportions, and in an equal volume of 70 per cent. alcohol; soluble in nitric acid at ordinary temperatures without the evolution of nitrous vapors. In the fresh state the oil is neutral to litmus, but when kept for some time it assumes an acid reaction, due to the formation of benzoic acid, which, when isolated and purified, should correspond to the tests given under Acidum Benzoicum. Oil of bitter almond containing a notable quantity of crystals of benzoic acid should not be dispensed. If 10 drops of the oil, dissolved in a little alcohol, be shaken with a few drops of solution of sodium hydroxide, then with a little ferrous sulphate test-solution, and finally mixed with a slight excess of hydrochloric acid, a blue precipitate will be produced (presence of hydrocyanic acid).—U. S.

Tests.—If the looped end of a piece of clean copper wire be held in a non-luminous flame until it glows, then cooled, and the loop dipped into benzaldehyde, ignited, and held so that the liquid burns outside of the flame, then if the loop be slowly brought in contact with the outer edge of the flame, no green tinge should be discernible (absence of chlorinated products). If a small strip of filter paper be folded in the form of a taper, saturated with oil of bitter almond, placed in a small porcelain dish, and if a clean beaker, moistened on the inner surface with distilled water, be inverted over the smaller dish, after igniting the taper a part of the products of combustion will be absorbed by the water; if the beaker be then rinsed with a little distilled water and the liquid filtered, the filtrate should yield no turbidity upon the addition of a few drops of silver nitrate test-solution, or if a slight turbidity appears, it should entirely disappear upon boiling the liquid (absence of artificial oils containing chlorinated products).—U. S.

Assay of Oil of Bitter Almond.—For Benzaldehyde.—The Pharmacopœia directs that the percentage of benzaldehyde present in the oil shall be determined by the method of assay given under Benzaldehydum (see page 288), using 12 drops of oil of bitter almond for each assay.

For Hydrocyanic Acid.—Mix in a 100 Cc. flask 1 Gm. of the oil of bitter almond to be tested with sufficient water and magnesium oxide (free from chlorides) to make an opaque mixture of about 50 Cc. Add to this 2 or 3 drops of potassium chromate test-solution, and then from a burette tenth-normal silver nitrate solution until a red tint is produced which does not again disappear by shaking (each Cc. of tenth-normal silver nitrate solution consumed corresponding to 0.002684 Gm. of hydrocyanic acid).—U. S.

In the official assay for hydrocyanic acid not less than 7.45 Cc., nor more than 15 Cc., of tenth-normal silver nitrate solution will be required to show that the amount of acid present is within the limits demanded.

The presence of alcohol, oil of turpentine, and other low-boiling adulterants can be detected by means of fractional distillation. To detect nitrobenzene, 2 Cc. of oil are shaken with 34 Cc. of 45 per cent. alcohol and the mixture set aside for 24 hours. At the expiration of this time nitrobenzene will have settled to the bottom of the tube.

For the detection of chlorine, which would indicate the presence of impure benzaldehyde from toluene, the following methods may be employed:

Detection of Chlorine as C_6H_4ClCHO, *etc.*—A small quantity of the oil to be examined is oxidized with a warm alkaline solution of potassium permanganate, any excess of the latter being decomposed by the addition of alcohol. The mixture is filtered and the filtrate acidified with pure dilute sulphuric acid. Upon cooling, the separated benzoic acid—which contains the chlorine substitution-products of the benzene ring in the form of chlorinated benzoic acid—is thrown on a filter and carefully washed. The benzoic acid is dissolved in pure potassium hydroxide solution, a little nitre added, the solu-

tion evaporated to dryness, and finally heated in a platinum dish. The incinerated residue is dissolved in water, the solution acidified with nitric acid, filtered, and tested for chlorine with silver nitrate.

Detection of Alkyl Chlorides, $C_6H_5CH_2Cl$, *etc.*—5 to 10 Gm. of the oil are heated to boiling in a distilling flask and the first 10 to 12 drops of the distillate are caught in 5 per cent. alcoholic potassium hydroxide solution. The alcoholic liquid is heated for a time in a flask connected with a reflux condenser. The alcohol is then volatilized, the residue treated with water, and the oily constituents (benzyl alcohol, etc.) removed by shaking out with ether. The aqueous liquid, strongly acidulated with nitric acid, is warmed for a short time in a dish. When cold the separated benzoic acid is removed by filtration, and the filtrate tested for chlorine.

Action and Uses.—The employment of oil of bitter almond and the symptoms and treatment of poisoning are fully described under ACIDUM HYDROCYANICUM DILUTUM (which see). The dose is from ¼ to 1 minim (0.015–0.05 Cc.).

OLEUM AMYGDALÆ EXPRESSUM, *U. S.*—Expressed Oil of Almond.

Oleum amygdalæ, Br.; *Oleum amygdalarum*, P. G.; *Oleum amygdalæ dulcis.*—*Almond oil, Oil of sweet almond*, E.; *Huile d'amande (douce)*, Fr.; *Mandelöl, Süssmandelöl*, G.

The fixed oil expressed from the seed of *Prunus Amygdalus*, var. *amara* or *dulcis*, L.—Fam. *Rosaceæ*. The fixed oil expressed from Bitter or Sweet Almond, U. S., Br., P. G.

Preparation.—To obtain an unobjectionable oil, the almonds are freed from adhering dust by agitating them upon a sieve and removing discolored pieces, after which they are ground or well bruised in an iron or stone mortar, enclosed in canvas bags, and subjected to considerable pressure between polished steel plates, which should not be heated beyond about 30° C. (86° F.). The oily edges of the press-cake may be powdered and again expressed, when an additional quantity of oil will be obtained. The yield is 40 to 54 per cent. from sweet, and 35 to 38 per cent. from bitter, almonds. Expressing the residue at a higher temperature will yield more oil, which, however, is of inferior quality. The expressed turbid oil is set aside in a cool place, and then decanted from the sediment, which may be filtered. The commercial oil is made principally from bitter almonds prior to preparation of the volatile oil.

Properties.—Expressed oil of almond is nearly colorless or of a pale-straw color (due to the episperm of the kernel), almost inodorous, and has a bland slightly nutty taste. It is a thin oily fluid having a specific gravity of 0.914–0.920 at 15° C. (59° F.) or 0.910–0.915 at 25° C. (77° F.). The oil is but slightly soluble in alcohol (24 parts, Allen), but soluble in all proportions in other fixed oils, ether, chloroform, benzene, and carbon disulphide. It remains clear at —10° C. (14° F.), but begins to congeal at —20° C. (—4° F.), whereby the presence of other oils may be detected, olive and lard oils congealing at —5° C. (22° F.) and apricot- and peach-kernel oils remaining fluid even at —20° C. (—4° F.). Almond oil belongs to the non-drying oils, and when exposed to air readily becomes rancid, acquiring an acrid taste.

Composition.—Expressed oil of almond consists chiefly of triolein, varying from 75 to 85 per cent., mixed with tripalmitin. Some authorities claim that trilinolein and tristearin are also present, but according to Gusserow the last-named fat is never found in the oil.

Adulterations.—Among the adulterations met with in almond oil may be mentioned olive, lard, sesame, ground-nut, poppyseed, cottonseed, apricot- and peach-kernel oils. The two last named are said to be frequently entirely substituted for almond oil.

Tests.—If 2 Cc. of the oil be vigorously shaken with 1 Cc. of fuming nitric acid and 1 Cc. of water, a whitish not red or brownish mixture should be produced, which, after standing for some hours at about 10° C. (50° F.), should separate into a solid, white mass, and a scarcely colored liquid (distinction from apricot- and peach-kernel oils, which give a *red*, and sesame and cottonseed oils, which give a *brown* coloration). If 10 Cc. of the oil be mixed with 15 Cc. of a 15 per cent. solution of sodium hydroxide and 10 Cc. of alcohol, the mixture allowed to stand at a temperature of 35° to 40° C. (95° to 104° F.), with occasional agitation, until it becomes clear, and then diluted with

100 Cc. of water, the clear solution thus obtained, upon the subsequent addition of an excess of hydrochloric acid, will separate a layer of oleic acid. This, when separated from the aqueous liquid, washed with warm water, and clarified on a water-bath, will remain liquid at 15° C. (59° F.), although sometimes separating particles of solid matter and becoming turbid. 1 part of this oleic acid, when mixed with 1 volume of alcohol, should afford a clear solution, which, at 15° C. (59° F.), should separate no fatty acids, nor become turbid on the further addition of 1 volume of alcohol (distinction from olive, arachis, cottonseed, sesame, and other fixed oils). Oil of almond, when saponified by means of alcoholic potassium hydroxide test-solution, should show a saponification value of 191–200. If 0.3 Gm. of almond oil be dissolved in 10 Cc. of chloroform and placed in a 250 Cc. flask with 25 Cc. of a mixture of equal parts of alcoholic iodine test-solution and alcoholic mercuric chloride test-solution, and after standing for 4 hours protected from the light, 20 Cc. of potassium iodide test-solution be added, and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate solution, an iodine figure of not less than 95 nor more than 100 should be obtained.—U. S. Saturated zinc chloride solution (Maben's reagent) produces no color reaction with pure almond oil, but develops a purplish-brown coloration with apricot- and peach-kernel oils. The presence of cottonseed oil may be detected by the Halphen and Becchi tests, and sesame oil by the furfurol test (see OLEUM GOSSYPII and OLEUM SESAMI). The spectrum of almond oil shows no absorption bands (distinction from other vegetable oils).

Action and Uses.—Expressed oil of almond may be given in the form of an emulsion for its demulcent properties. The dose is from 1 to 8 fluidrachms (4–30 Cc.).

OLEUM ANETHI, *Br.*—Oil of Dill.

Essence d'aneth, Fr.; *Dillöl*, G.

The volatile oil obtained by steam distillation from the fruit of *Anethum graveolens* L.—Fam. *Umbelliferæ*. Yield about 3–4 per cent. East Indian and Japanese dill oil is obtained from *Anethum sowa* DC. and differs both physically and chemically from the oil official in the Br. P.

Properties.—According to the Br. P., the oil should have a pale-yellow color, its odor should be that of the fruit, the taste sweet and aromatic. The specific gravity may vary between 0.905 and 0.920; the angle of rotation $= +70°$. According to other authorities, the specific gravity varies between 0.895 and 0.915; the angle of rotation $= +75°$ to $+80°$. Dill oil forms a clear solution with 5–8 parts of 80 per cent. alcohol.

Composition.—Like caraway oil, dill oil contains *d*-carvone, $C_{10}H_{14}O$ (40–60 per cent.) and *d*-limonene, $C_{10}H_{16}$. English and Spanish oils appear to contain appreciable amounts of phellandrene, whereas German oil contains but traces. Dill apiol, which is found in the East Indian oil, does not appear to be contained in the European oils. The German variety appears to contain paraffin.

The amount of carvone, the principal constituent of the oil, can be determined by the carvoxime assay method (see OLEUM CARI).

Action and Uses.—Oil of dill may be given internally as a carminative in doses of from 2 to 10 minims (0.10–0.6 Cc.). When locally employed, it is said to possess anodyne properties.

OLEUM ANIMALE ÆTHEREUM.—Animal oil.

Oleum animale Dippeli, Oleum corni cervi rectificatum.—Dippel's animal oil, E.; *Huile animale de Dippel*, Fr.; *Dippelsches Thieröl*, G.

Preparation.—When bones and other animal substances are subjected to dry distillation, a fetid, brown, thick, oily liquid is obtained to which the names *Oleum animale fœtidum, Oleum cornu cervi; Bone oil, Crude animal oil*, E.; *Rohes oder stinkendes Thieröl, Hirschhornöl*, G., are applied. This crude oil is purified for medicinal use by distilling it in a retort or flask, heated on a sand-bath as long as a thin oil passes over, which is then mixed with 4 times its weight of water, and rectified in a metallic still as long as the distillate is colorless or but slightly yellow. The oily liquid is separated from the water, and at once put into small vials, well corked, and preserved in a dark place.

Properties.—Rectified animal oil is a colorless or yellowish thin, oily liquid, of 0.75–0.85 specific gravity. It has a very penetrating peculiar but not fetid odor, and a pungent, acrid, afterward cooling and bitter taste. It shows a slight alkaline reaction toward litmus-paper, is soluble in 80 parts of water, and mixes clear with alcohol, ether, and fixed and volatile oils in all proportions. Exposed to light and air, it rapidly darkens and acquires a thicker consistence.

Constituents.—This is a very complex mixture, containing pyrrol, pyridine, picoline, lutidine, and collidine; also methylamine, propylamine, and others.

Action and Uses.—Animal oil is practically never employed in medicine at the present time. It was formerly given internally in doses of from 10 to 30 minims (0.60–2 Cc.) as a tæniacide, a diffusible stimulant in typhoid states, and a remedy for hysteria and other nervous disorders. It has also been locally applied in the treatment of sciatica and chronic rheumatic conditions.

OLEUM ANISI, *U. S., Br., P. G.*—Oil of Anise.

Essence d'anis, Fr.; *Anisöl*, G.

According to the U. S. P. and Br. P., oil of anise is the volatile oil distilled from the fruit of *Pimpinella anisum* L.—Fam. *Umbelliferæ*, or from the star-anise, the fruit of *Illicium verum* Hook. fil.—Fam. *Magnoliaceæ;* the P. G. applies the term "Oleum anisi" to anethol and defines it as "the oxygenated constituent of the volatile oil of anise."

Commercially a distinction is not often made between the oils of anise and of star-anise. The numerous varieties of anise not only afford a different yield, but also afford oils that differ slightly in odor and specific gravity, and consequently in composition.

Properties.—At temperatures above its congealing-point, 15° to 19° C. (59°–66.2° F.), anise oil is a colorless, highly refractive liquid of characteristic anise-like odor and sweet taste. In the cold it congeals to a snow-white, crystalline mass. Before being dispensed, anise oil which has congealed entirely or in part should be completely liquefied and thoroughly mixed. The specific gravity of the liquid oil is 0.975–0.985 at 25° C. (77° F.); the angle of rotation $= -1°\ 50'$. It is soluble in 1.5 to 5 parts of 90 per cent. alcohol.

Composition.—The principal constituent of anise oil is anethol, also known as *p*-propenylanisol ($C_{10}H_{12}O$ or $C_6H_4.C_3H_5.OCH_3$), which is present to the extent of 80–90 per cent. Exposed to air this is oxidized to anisic aldehyde and acetic aldehyde, the former also to anisic acid. Exposed to light, anethol is polymerized to photoanethol. All these substances are found in old oil, especially when not properly kept. Besides anethol, anise oil contains its liquid isomer, methyl chavicol, and terpenes.

Star-anise oil contains much the same constituents found in anise oils (anethol 80–90 per cent.). The terpenes in this case have been identified as *d*-pinene and *d*-phellandrene. In addition it contains traces of the ethyl ether of hydroquinone and possibly safrol.

Japanese star-anise oil, which is distilled from the leaves, contains but 25 per cent. of anethol, eugenol, safrol, and terpenes. Fennel oil contains, besides 50–60 per cent. of anethol, *d*-fenchone, and pinene. Bitter fennel oil contains anethol, methyl chavicol, fenchone, pinene, and possibly anise ketone, phellandrene, and cymene.

Adulterations.—The substitution of star-anise oil for anise oil is not regarded as adulteration. Fair dealing, however, demands that both oils be sold under their proper label. Adulteration in connection with this oil is chiefly practised by removing part of the anethol, or by the addition of oil from which the anethol has been removed. Other anethol-containing oils are likewise used *in toto* or in part for this purpose. In addition the common, more crude adulterants, such as alcohol, petroleum, etc., have been observed.

Tests.—Many of the crude adulterants, such as alcohol, turpentine oil, etc., are indicated by variations from the standard physical constants. Anise oil being rich in oxygenated constituents, its solubility in alcohol is of importance.

Whereas some chemists maintain that anise oil should be valued by its combined phenol ether content (anethol and its isomer methyl chavicol to be determined jointly by a methoxy determination), it is generally valued according to its anethol content.

The U. S. P. gives the following tests to show the quality of oil of anise: The oil should be slightly lævogyrate, up to —2°, at a temperature of 25° C. (77° F.) (absence of

oil of fennel, etc.). It should be soluble in an equal volume of alcohol, forming a clear solution, also in 5 volumes of 90 per cent. alcohol (absence of petroleum, of most fixed oils, and of oil of turpentine). An alcoholic solution of oil of anise is neutral to litmus-paper, and should not assume a blue or brownish color on the addition of a drop of ferric chloride test-solution (absence of some volatile oils containing phenols). When the oil is shaken with water in a narrow graduated cylinder, its volume should not be diminished (absence of alcohol). When tested according to the following method, the congealing-point of oil of anise should not be below 15° C. (59° F.): Transfer about 10 Cc. of the oil to a test-tube, placed in water cooled with ice; insert a thermometer at once into the oil, and allow it to remain undisturbed until its temperature has fallen to about 6° C. (42.8° F.). Induce crystallization either by scratching the inner wall of the test-tube with the thermometer, or by the addition of a particle of solid anethol, and stir continuously during the solidification of the oil. The highest temperature reached during the crystallization is regarded as the congealing-point.—U. S.

Action and Uses.—Oil of anise is a carminative and stimulant in the treatment of flatulent colic. It may also be combined with purgatives to prevent griping. The dose is from 1 to 5 minims (0.05–0.3 Cc.).

OLEUM ANTHEMIDIS, *Br.*—Oil of Chamomile.

Oleum chamomillæ romanæ.—Essence de camomille romaine, Fr.; *Römisch Kamillenöl*, G.

The volatile oil obtained by steam distillation from the flowers of *Anthemis nobilis* L.—Fam. *Compositæ*. At the present time the oil is distilled principally in Mitcham, near London, where the plant is cultivated. The dried flowers yield about 0.8–1 per cent. of oil.

Properties.—According to the British Pharmacopœia, the oil is pale-blue or greenish-blue when freshly distilled, but gradually becomes yellowish-brown due to the influence of light and air. It should have the aromatic taste and odor of the flowers. Specific gravity, 0.905 to 0.915; angle of rotation = +1° to +3°. Usually the oil has a faintly acid reaction; saponification number, 250–300. As a rule it forms a clear solution with 6 parts of 70 per cent. alcohol, but occasionally a larger paraffin content renders it less soluble.

Composition.—This oil consists principally of a mixture of isobutyl, amyl, and hexyl esters of butyric acid, methacrylic acid, and the isomeric angelic and tiglinic acids. It also contains an isomer of camphor, termed anthemol, and possibly paraffin.

Action and Uses.—Oil of chamomile is antispasmodic, stimulant, and carminative. It may be given to expel flatus or moderate the griping of purgative drugs. The dose is from 1 to 5 minims (0.05–0.3 Cc.).

OLEUM AURANTII CORTICIS, *U. S.*—Oil of Orange-peel.

Oleum aurantiorum.—Essence of orange, E.; *Essence d'orange*, Fr.; *Pomeranzenschalenöl*, G.

Oil of orange-peel is a volatile oil obtained by expression from the fresh peel of the sweet orange, *Citrus Aurantium* L.—Fam. *Rutaceæ*.

In accordance with the source, commercial distinction is made as to sweet and bitter orange oil:

1. Oleum Aurantii Dulcis (*Oil of sweet orange*, E.; *Essence d'orange*, Port., Fr.; *Süsses Pomeranzenschalenöl, Süsses Orangenschalenöl, Apfelsinenschalenöl*, G.).—This is the official oil.

2. Oleum Aurantii Amari (*Oil of bitter orange*, E.; *Essence d'orange bigarade*, Fr.; *Bitteres Pomeranzenschalenöl*, G.).—This is derived from *Citrus amara* (L.) Lyons (*C. vulgaris* Risso), and was likewise official in the 1890 Pharmacopœia. Though chemically indistinguishable thus far from the sweet orange oil, it is regarded as having a superior flavor. However, but a very small amount is produced, and this is often adulterated with sweet orange oil. Most pharmacopœias, recognizing this fact, direct the use of the fresh bitter rind in place of the oil for flavoring purposes.

Preparation.—Like the other citrus fruit oils, oil of orange is not obtained by steam distillation, but by mechanical process (comp. oil of lemon). The principal

centre of production of these oils is southern Italy and Sicily. In Jamaica an oil is prepared by distillation, but it is much inferior.

Properties.—Oil of orange is a pale yellow to yellowish-brown liquid of a characteristic orange odor, and a mild, aromatic, not bitter taste. The oil from bitter orange-peel differs by its somewhat bitter taste. Specific gravity, 0.848–0.852 at 15° C. (59° F.), or 0.842–0.846 at 25° C. (77° F.); angle of rotation = + 96° to + 98° at 20° C. (not less than 95° in a 100-Mm. tube, at a temperature of about 25° C. (77° F.), U. S. P.). Between 175° and 180° C. (347° and 356° F.) about nine-tenths of the oil distil over. On account of the presence of wax-like, non-volatile substances of unknown composition, which separate in part upon standing, the oil as a rule does not form a clear solution with 90 per cent. alcohol. The U. S. P. demands that it be soluble in 4 volumes of alcohol, the solution being neutral to litmus-paper. The oil is also soluble in an equal volume of glacial acetic acid, and in all proportions of absolute alcohol.

Composition.—Limonene constitutes more than 90 per cent. of the oil. About 5 per cent. of the oil constitutes the principal odor-bearers, among which citral, citronellal, and the methyl ester of anthranylic acid have been identified. Other substances are present. Of the so-called stearoptene, which finds its way into the oil by the expression of the rind, and which remains in the residue when the oil is distilled, nothing is known. Inasmuch as some of the principal odor-bearers are at least in part destroyed by steam distillation, oil of orange that has acquired a terebinthinate odor upon standing should not be rectified by steam distillation.

Adulterations.—Distilled oil of orange is colorless, but its addition in small amounts to expressed oil may scarcely be detected unless by the highly developed sense of smell of the expert. The same holds true of the terpene wastes resulting in the manufacture of concentrated or terpeneless oils of orange.

Alcohol can readily be detected in the usual manner, but owing to the high terpene content of oil of orange, the addition of turpentine oil is not indicated by the alcohol-solubility test nor by the specific gravity. Turpentine oil and some other possible adulterants, however, affect the angle of rotation materially. Whenever the angle of rotation of a given oil comes near the lower limit, it may be necessary to make corrections for differences in temperature, about 14′ for each degree in temperature. To determine the presence of oil of turpentine, the Pharmacopœia directs that when subjected to careful fractional distillation, any oil coming over below 170° C. (338° F.) should not yield pinene nitrosochloride and nitrosopinene when tested in the following manner: Dissolve 5 Cc. of the fraction coming over below 170° C. (338° F.) in ½ its volume of glacial acetic acid, add 5 Cc. of amyl nitrite, cool thoroughly in a freezing mixture, and add, very gradually, 5 Cc. of a mixture of equal volumes of hydrochloric acid and glacial acetic acid. If pinene is present, crystals of pinene nitrosochloride will separate after a time from the blue or greenish liquid. Collect these on a force filter and wash them with a little alcohol. Transfer the crystals to a flask, add 5 Cc. of alcoholic potassium hydroxide test-solution, and heat on a water-bath 15 minutes. Pour the solution into cold water, collect the precipitate, and wash it with cold water. Recrystallize the dried precipitate from alcohol and determine the melting-point of the crystals. Nitrosopinene melts at 132° C. (269.6° F.), whereas nitrosolimonene or carvoxime (from limonene, one of the normal constituents of oil of orange-peel) melts at 72° C. (161.6° F.).

Action and Uses.—Oil of orange-peel is employed in medicine only as a flavoring agent. Persons employed in its manufacture frequently suffer from papular or vesicular eruptions of the skin, headache, neuralgia, and mental confusion.

OLEUM BERGAMOTTÆ.—Oil of Bergamot.

Oleum Bergamii.—Essence de bergamotte, Fr.; *Bergamottöl,* G.

Oil of bergamot is a volatile oil obtained from the fresh rind of the fruit of *Citrus Bergamia* Risso et Poit (*C. Aurantium Bergamia* W. et A.—Fam. *Aurantiaceæ*), the Bergamot Orange or Bergamot Lemon. The botanical origin of this so-called species is very obscure. It is unknown in a wild state and, to the best of our knowledge, originated abruptly from cultivated plants. It is variously regarded as a variety of *C. Limetta* or of *C. Limonum,* or a hybrid of *C. medica* and *C. Aurantium.* The latter

origin appears to us the most probable. The fruit is of a lemon-yellow color, and its juice has a bitter and acrid taste.

Preparation and Properties.—Oil of bergamot is usually obtained by cold expression in a machine so constructed that while the fruit is kept in a rotatory motion, the oil-vessels contained in the rind are ruptured with slight pressure; the oil thus obtained deposits on standing a waxy matter, from which it is decanted. An inferior quality of oil is obtained by distilling the crushed rind with steam. The oil varies in color from brownish-yellow to green, and has a very pleasant odor and a bitterish aromatic taste. Its specific gravity ranges from 0.882 to 0.886 at 15° C. (59° F.), and its boiling-point lies between 180° and 195° C. (356° and 383° F.). It has a neutral or slightly acid reaction to test-paper and deflects polarized light to the right. Oil of bergamot is soluble in one-quarter or one-half of its volume of 90 per cent. alcohol, and the addition of larger quantities of the alcohol does not cause turbidity. Some samples of the oil have been found to form clear solutions with 80 per cent. alcohol, while others, especially rich in ester-content, produce turbid mixtures. Upon evaporation on a boiling water-bath a residue of a waxy nature is obtained amounting to 5 or 6 per cent. and identical with the waxy deposit often found in the commercial oil, which is composed chiefly of bergaptene (see *Composition*).

Composition.—Oil of bergamot owes its value in perfumery chiefly to its content of linalyl acetate, of which ester from 30 to 40 per cent., and at times even 45 per cent., is present. In addition it contains linalool, some dextro-limonene, and 5–6 per cent. of bergaptene, an odorless compound which has been shown to be the lactone of bergaptenic acid, and has the composition $C_{12}H_8O_4$. Bergaptene has been obtained in the form of delicate, white, silky needles, which are tasteless and at ordinary temperature also odorless, and which melt at 188° C. (370.4° F.).

Adulterations.—Oil of bergamot has been adulterated with oil of orange, oil of turpentine, and inferior oils of bergamot obtained by distillation of the partly exhausted rind or of the leaves with water. The decreased solubility in alcohol and an increase or deficiency in the weight of residue obtained by evaporation of the oil at 100° C. (212° F.) will serve to detect adulteration.

Action and Uses.—Oil of bergamot possesses aromatic and stimulating properties, and is employed as a flavoring agent in hair tonics and to disguise the unpleasant odor of certain drugs in dusting-powders and ointments.

OLEUM BETULÆ, *U. S.*—Oil of Betula.

Oleum betulæ volatile, U. S., 1890; *Oleum betulæ lentæ.—Oil of sweet birch*, E.; *Essence de betula*, Fr.; *Birkenrindenöl*, G.

A volatile oil obtained by distillation from the bark of the sweet birch, *Betula lenta* L.—Fam. *Betulaceæ*, after the bark has been macerated for about 12 hours in order to admit of the hydrolysis of the glucoside gaultherin into methyl salicylate and a sugar.

This oil is commonly known as oil of wintergreen, or in recent years as natural wintergreen oil, in order to distinguish it from artificial methyl salicylate. Commercially it is not often distinguished from true wintergreen oil, from *Gaultheria procumbens*, which it resembles closely.

Properties.—Oil of sweet birch is colorless when rectified, a reddish colored oil indicating contact with metal (iron) from the still or containers. As to odor and taste, it cannot readily be distinguished from pure methyl salicylate, somewhat more readily from true wintergreen oil. Its specific gravity varies between 1.180 and 1.187. Like methyl salicylate, it is optically inactive, differing in this respect slightly from fresh true wintergreen oil.

Composition.—Its similarity in odor and taste with true wintergreen oil was recognized early in the nineteenth century. Procter (1843) regarded it identical with true wintergreen oil. The U. S. P. of 1890, in which it was first made official, pronounced it as identical with methyl salicylate, and as "nearly identical" with true wintergreen oil. According to Power and Kleber, it consists of about 99.8 per cent. of methyl salicylate, the remaining fraction of 1 per cent. consisting of paraffin and an ester, $C_5H_9COOC_8H_{15}$, to which it owes its slight difference in odor from methyl salicylate.

Tests.—The most common admixture is artificial methyl salicylate. If perfectly pure, this defies detection; if impure, it may be detected by means of its impurities (see

METHYLIS SALICYLAS). Most adulterants will be indicated physically by changes in the specific gravity, angle of rotation, and boiling-point (the boiling-point of methyl salicylate is given as 224° C. (435.2° F.) corrected). Chemically they are often indicated by the incomplete solubility in aqueous alkali (comp. methyl salicylate). Substances soluble in water, like alcohol, or soluble in aqueous alkali, like the phenols, are not indicated in this way. Turpentine oil and petroleum, the crude adulterants formerly used more extensively, are readily separated in this manner, and can be identified by their physical and chemical properties.

For the purpose of ascertaining the amount of methyl salicylate with an approximate degree of accuracy, its solubility in an aqueous solution of potassium hydroxide can be made use of, a graduated cylinder being employed; provided, however, such soluble substances as alcohol and phenols have been found absent. For a greater degree of accuracy the amount of methyl salicylate can be ascertained titrimetrically by saponification with standard alkali and back titration of the excess of alkali with standard acid.

Action and Uses.—Oil of sweet birch is employed for the same purposes and in the same doses as OLEUM GAULTHERIÆ (which see).

OLEUM BUBULUM.—Neat's-foot Oil.

Oleum pedum tauri, Axungia pedum tauri.—Huile (Graisse) des pieds du gros bêtail, Fr.; *Klauenöl, Ochsenklauenfett*, G.

Preparation.—Neat's-foot oil is obtained by boiling neat's feet, deprived of their hoofs, with water, skimming off the oil which rises to the surface, and keeping it for some time on warm water. After the impurities have settled it is ready for use.

Properties.—Neat's-foot oil is a pale-yellow and (when of good quality) nearly inodorous and bland, liquid oil, which has the specific gravity 0.915 at 15° C. (59° F.), is but slightly thickened on exposure, does not readily turn rancid, and requires to be cooled to below the freezing-point of water before it congeals to a soft white mass. It consists mostly of olein, containing according to Coste and Parry (1898) about 3.5 per cent. of free fatty acid, and is soluble in the usual solvents of fixed oils. Its reactions with sulphuric acid, nitric acid, and the elaïdin test simulate those of lard oil. Its saponification value is 189–197; its iodine value is 65.3 to 72.4; and its thermal value (Maumené test) 47–48 degrees C.

Action and Uses.—Neat's-foot oil has been employed in medicine as a substitute for codliver oil, but because of its disagreeable odor and tendency to cause diarrhœa is rarely prescribed. The dose is from 1 to 2 fluidrachms (4–8 Cc.).

OLEUM CADINUM, *U. S., Br.*—Oil of Cade.

Oleum juniperi empyreumaticum.—Juniper tar oil, E.; *Huile de cade*, Fr.; *Kadeöl, Radiöl*, G.

Oil of cade is an oily product obtained by the destructive distillation of the wood of *Juniperus Oxycedrus* L.—Fam. *Pinaceæ* or *Coniferæ*, the African, Spanish, or Prickly Cedar or Large Brown-fruited Juniper, a species of the Mediterranean region, quite similar to *J. communis* and *J. Sabina*.

Oil of cade was made official in the 1890 edition of the U. S. P. and in the 1898 edition of the Br. P. It is official in all pharmacopœias with the exception of the Italian, Japanese, and Russian.

As a product of destructive distillation it is not classed with the volatile oils proper. The empyreumatic oil resulting from the destructive distillation of ordinary juniper wood is said to be substituted in the market for the pharmaceutical article. This may account for some of the differences that have been observed.

Properties.—Oil of cade is a brown, clear, thick liquid possessing a tarry odor and an empyreumatic, burning, somewhat bitter taste. Its specific gravity at 15° C. (59° F.) is about 0.990. In water it is almost insoluble, but imparts to it an acid reaction. In alcohol it dissolves only partially, but ether, chloroform, and carbon disulphide dissolve it completely.

Composition.—Some commercial oils are rich in cadinene, whereas others appear to contain but little. Inasmuch as the oil is used principally in the treatment of skin dis-

eases, its cadinene content may be of little consequence. Of the phenols, which apparently should be regarded as the more important constituents, but little is known.

Action and Uses.—Oil of cade may be employed in the treatment of favus, psora, eczema, psoriasis, and other chronic skin lesions. It is usually incorporated with an ointment base, or it may be mixed with some fixed oil and saponified with sodium hydroxide. Either the ointment or the soap should be applied at night and allowed to remain until morning.

OLEUM CAJUPUTI, *U. S., Br.*—Oil of Cajuput.

Oleum cajeputi.—Oil of cajeput, E.; *Essence de cajeput,* Fr.; *Cajeputöl,* G.

Oil of cajuput is a volatile oil obtained by water or steam distillation from the fresh leaves and twigs of *Cajuputi viridiflora* (Gærtn.) Lyons (*Melaleuca v.* Gærtn.; *M. Leucadendron* L.; *M. Cajuputi* Roxb.)—Fam. *Myrtaceæ.* The Cajuput is a small and beautiful tree of the East Indies, Australia, etc., somewhat resembling the Allspice and Jamaica Bay. It is said that a portion of the oil of commerce is distilled from other species, of the same region, *C. ericifolia* (Sm.) Lyons (*M. ericifolia* Sm.) being specially named. Whereas the oil from *C. acuminata* has an odor resembling slightly that of juniper berries, and the oil from *C. uncinata* yields a fraction with a decided rosemary odor, the majority of these oils resemble cajuput oil as to odor. Commercially they do not always appear to be kept distinct. The U. S. P. demands that oil of cajuput, when assayed by the process given below, shall yield not less than 55 per cent. of cineol.

The oil is official in most pharmacopœias, but not in the latest editions of the pharmacopœias of Germany and Austria. It is, however, enumerated in the unofficial supplement to the P. G. published by the German Apothecaries' Society.

Cineol (eucalyptol or cajuputol), quantitatively and possibly therapeutically, the principal constituent of the cajuput oils, is likewise official in the U. S. P. The new Swedish Pharmacopœia has made cineol official in place of cajuput oil.

Origin.—The oil does not appear to have been brought to Europe until the beginning of the seventeenth century, when the Dutch took possession of the Moluccas. Up to 1730 it was rare and expensive. Since then larger quantities come into the European market through Amsterdam. In Germany it was first called *Oleum Wittnebianum.* In France and England it does not appear to have been used until the beginning of the nineteenth century.

Oil of cajuput is obtained in a primitive manner by the natives of some of the Molucca Islands. The oil is shipped in empty wine and beer bottles, 25 of which are packed in a crate. Macassar on Celebes is the principal commercial center. The total export from this place in 1897 was 78,543 kilos, of which Amsterdam received but 2100. Hamburg and London are the other ports of import. Most of the oil is consumed in the orient, especially in British India.

Properties.—Oil of cajuput is a light, thin liquid. The crude oil is mostly greenish, presumably due to the presence of copper. The rectified oil is colorless. It has a peculiar, rather agreeable, distinctly camphoraceous odor (cineol), and an aromatic bitterish taste. The U. S. P. allows a range in specific gravity of from 0.915 to 0.925 at 25° C. (77° F.). It should be miscible with alcohol in all proportions, and the alcoholic solution should be neutral to litmus. It is also soluble in 1 part of 80 per cent. alcohol. Acidity might be due to oxidation of the aldehydes of an unrectified oil. The oil is lævogyrate, and its angle of rotation should not exceed —2° in a 100-Mm. tube at a temperature of 25° C. (77° F.). The presence of the proper amount of cineol may be determined by combining the latter with phosphoric acid, as follows: "Introduce into a beaker a solution prepared by dissolving 10 Cc. of oil of cajuput in 50 Cc. of purified petroleum benzin; immerse the beaker in a freezing mixture and add phosphoric acid, drop by drop, with constant stirring, until the white magma of cineol phosphate formed begins to assume a yellowish or pinkish tint; then transfer the magma to a force filter, wash it with cold purified petroleum benzin, and then dry it by pressure between two porous plates. Transfer the precipitate (cineol phosphate) to a narrow graduated cylinder and add warm water, which will cause separation of the cineol. The volume in cubic centimeters of the separated oily liquid, multiplied by 10, represents the volume per cent. of cineol."—U. S.

Composition.—The principal constituent of this oil was analyzed correctly by Blanchet as early as 1833. Its identity with cineol, $C_{10}H_{18}O$, was first established by Wallach in 1884. An isomer of this oxide, the crystalline alcohol terpineol, $C_{10}H_{17}OH$,

was found free and as acetic ester by Voiry. Quantitatively this ranks second. Of the terpenes present to a small extent, lævopinene was identified. Voiry also separated aldehydes which are possibly identical with valerianic and benzoic aldehydes. These upon oxidation may impart an acid reaction, especially to a non-rectified oil. The possible presence of traces of copper in the crude oil has been alluded to.

Adulterations.—To what extent the oils from other species are added to commercial oils, it is difficult to state and equally difficult to determine experimentally. Inasmuch as lævorotatory pinene is a constant constituent of the oil, the detection of lævogyrate (*e. g.*, French) turpentine oil is rendered especially difficult. The presence of larger amounts, however, could be detected in the usual manner. On shaking 5 Cc. of the oil with 5 Cc. of water containing 1 drop of diluted hydrochloric acid, a reddish-brown color should not be produced in the acid liquid separated from the oil if a drop of potassium ferrocyanide test-solution be added (absence of copper).

Action and Uses.—Full doses of oil of cajuput produce a sensation of warmth in the gastro-intestinal tract, increase the force and rapidity of the heart's action, and in some cases cause excessive sweating. If given internally in overdose, it produces severe gastro-intestinal irritation. Like other similar volatile oils, it may be locally applied in the treatment of pediculus pubis, tinea tonsurans, pityriasis, psoriasis, and acne rosacea. It has also been recommended as a valuable addition to liniments in the treatment of chronic gouty and rheumatic pains and in neuralgia. Because of its anæsthetic properties it may be inserted upon a pledget of cotton into the cavity of a carious tooth for the relief of toothache. This remedy has been given internally in the treatment of serous diarrhœa, flatulent dyspepsia, choleraic conditions, chronic vesical catarrh, and chronic bronchitis. Oil of cajuput has also been employed as a vermifuge. The internal dose is from 5 to 20 minims (0.3–1.30 Cc.). When used externally, it may be added to camphor liniment or diluted with an equal amount of olive oil.

OLEUM CALAMI, *P. G.*—Oil of Calamus.

Essence de calamus, Fr.; *Kalmusöl, Calmusöl*, G.

Oil of calamus is obtained by steam distillation from *Acorus Calamus* L.—Fam. *Araceæ*.

Properties.—Calamus oil is somewhat viscid in consistence, of a yellow to brownish-yellow color, possesses an aromatic, camphor-like odor and a bitter taste. Its specific gravity, according to the P. G., varies between 0.960 and 0.970; its angle of rotation = +10° to +31°; saponification number 16–20, after acetylization 40–50. It is readily soluble in 90 per cent. alcohol. According to the P. G., a mixture of 1 Gm. of oil with 1 Gm. of alcohol should be colored a dark reddish-brown by 1 drop of ferric chloride test-solution.

Composition.—Next to nothing is known about the chemistry of the oil. It possibly contains pinene and a sesquiterpene. One of the higher fractions is blue in color, and the highest fraction apparently contains a phenol (compare the test above).

Action and Uses.—See CALAMUS, the properties of which are almost entirely due to its volatile oil.

OLEUM CARI, *U. S., Br., P. G.*—Oil of Caraway.

Oleum carui, Br.; *Oleum carvi*, P. G.—*Essence de carvi*, Fr.; *Kümmelöl*, G.

Oil of caraway is obtained by steam distillation from the fruit of *Carum carui* L.—Fam. *Umbelliferæ*. In the P. G. the caraway oil proper is no longer official, but under the same name its principal constituent, the ketone carvone, is recognized. Commercially this is also known as "Kümmelöl, extra stark." The *Oleum carvi* of the P. G., however, should not be confounded with a merely concentrated or terpeneless caraway oil. It is supposed to be chemically pure carvone.

Rectified caraway oil is, properly speaking, an oil improved by redistillation with steam. It is reported that the term "rectified" is sometimes applied to an oil from which a part of the carvone has been removed, evidently by fractional distillation with steam. Such an oil would correspond more or less therefore to "light" caraway oil. This residue, after the carvone has been removed, also enters the market under the designation "carvene." It consists principally of limonene.

Properties.—Oil of caraway should be colorless or pale-yellow in color, possess an

odor characteristic of caraway, and a mild spicy taste. The specific gravity requirements of the U. S. P. are 0.905 to 0.915 at 25° C. (77° F.); those of the Br. P. 0.910 to 0.920 at 15.5° C. (60° F.). A normal oil with a lighter specific gravity can easily be brought up to this requirement by removal of part of the limonene. If the carvone content is naturally low, such an oil is possibly as objectionable as a richer one from which part of the carvone has been removed. The specific gravity requirement of the P. G., viz., 0.960, is that of pure carvone. Oil of caraway is soluble in an equal volume of alcohol; also in from 3 to 10 volumes of 80 per cent. alcohol.—U. S.

Carvone boils at 223°–224° C. (433.8–435.2° F.), limonene at 175°–176° C. (347°–348.8° F.). The angle of rotation of the oil varies between +70° and +80°, or as high as +85°; for carvone it is +62.5°, and for limonene about +125°. The rotatory power of the oil will therefore increase with a diminished carvone content.

Composition.—The principal constituents of caraway oil are *d*-carvone and *d*-limonene in about equal amounts. There appear to be present an alcohol, $C_{10}H_{17}OH$, and other substances more prone to decomposition, which are removed, at least in part, in the process of rectification. In the aqueous distillate of the oil, methyl alcohol, acetaldehyde, furfurol, and diacetyl have been found. Hydrogen sulphide is also found in considerable amount at the beginning of the distillation.

Tests.—Inasmuch as caraway oil is valued almost entirely in accordance with its carvone content, a carvone assay is of importance. Fractionation has been resorted to: not more than 25 per cent. should distil below 185° C. (365° F.), and at least 55 to 65 per cent. above 200° C. (392° F.), a considerable fraction—40 to 50 per cent.—being obtained at from 220° to 230° C. (428° to 446° F.).

This method, however, is somewhat unsatisfactory. The carvoxime method yields not only more accurate results, but also a definite chemical compound in crystalline form.

To a solution of 10 Gm. of oil, dissolved in 25 Cc. of alcohol, 5 Gm. of hydroxylamine hydrochloride and 6.5 Gm. of sodium bicarbonate are added. This mixture is boiled on a water-bath for half an hour in a flask connected with a reflux condenser, 25 Cc. of water are then added, and the alcohol is distilled off on the water-bath. Steam is then passed through the liquid until traces of carvoxime come over. The last portions of the distillate are collected separately in test-tubes, and when traces of crystals of carvoxime appear on the surface the operation is interrupted. The tube of the condenser is washed with a little hot water, and this, as well as the last collected distillate, containing some carvoxime, is returned to the flask. The contents of the flask are allowed to cool, and after the carvoxime has completely solidified, it is removed from the sides of the flask by means of a loop of stiff wire, thrown upon a force filter, washed, and dried by suction. The air-dried carvoxime is transferred to a tared glass dish and heated for 1 hour on a water-bath, and when cool weighed. To the weight thus obtained 0.100 Gm. is added, as this is about the quantity lost during heating. From the weight of the carvoxime that of the carvone may be readily calculated, 164.67 parts of the former corresponding to 149.66 parts of the latter, or the weight of carvoxime obtained, expressed in Gm., when multiplied by 0.9088, gives the weight of the equivalent amount of carvone.

Action and Uses.—Oil of caraway is stimulant and carminative, and may be employed in the treatment of flatulent colic. It is used to impart an agreeable flavor to other remedies and to prevent the griping of purgative drugs. The dose is from 1 to 10 minims (0.05–0.6 Cc.).

OLEUM CARYOPHYLLI, *U. S., Br., P. G.*—Oil of Cloves.

Oleum caryophyllorum.—Essence de girofle, Fr.; *Nelkenöl*, G.

The term oil of cloves is commonly used to designate the volatile oil from the unexpanded flowers of *Eugenia aromatica* (L.) O. Kuntze—Fam. *Myrtaceæ*. The German Pharmacopœia, however, applies it to eugenol, the principal oxygenated constituent of this oil. The U. S. P. requires that oil of cloves, when assayed by the process given below, shall contain not less than 80 per cent. of eugenol. Oil of clove stems, although closely related, is not official, neither is the oil of clove bark, derived from a different plant.

Zanzibar and Pemba cloves, which appear to be used almost exclusively for the distillation of the commercial oil, yield about 15 to 18 per cent.

Properties.—Freshly distilled oil of cloves is yellowish or almost colorless, but it

darkens with age. The specific gravity of a normal oil may vary between 1.040 and 1.060 at 25° C. (77° F.) (U. S.). According to the Br. P., it should not fall below 1.050. The specific gravity requirement of the P. G., viz., 1.072 to 1.074, is that of eugenol, one of the heaviest constituents of the oil. It is soluble in an equal volume of alcohol, this solution being slightly acid to litmus-paper; also soluble in 2 parts of 70 per cent. alcohol, but older oils do not always form a perfectly clear solution. If 2 drops of the oil be dissolved in 4 Cc. of alcohol and a drop of ferric chloride test-solution added, a bright green color will be produced; and if the same test be made with a drop of diluted ferric chloride test-solution, prepared by diluting the test-solution with four times its volume of water, a blue color will be produced, which soon changes to yellow (U. S.). Inasmuch as the bulk of the oil consists of a phenol, it is in large part soluble in aqueous caustic alkali (hence the former name, eugenic acid, for eugenol).

Composition.—Quantitatively, and finally also therapeutically, the principal constituent of oil of cloves is eugenol, a phenol, of which from 70 to 85 per cent. is present. In addition to free eugenol, there appears to be present aceteugenol, its acetic ester; also the eugenol ester of acetsalicylic acid. Quantitatively second in importance is the sesquiterpene caryophyllene. Other minor constituents are methyl amyl ketone, vanillin, furfurol (to which some ascribe the darkening of the oil), and methyl alcohol. The fatty ketone is said to impart to the oil its peculiar fruity odor as distinguished from the more heavy eugenol odor (distinction from clove stem oil).

Tests and Adulterations.—Oil of cloves may be sophisticated by the abstraction of eugenol or by the addition of eugenol from other sources—*e. g.*, clove stem oil. Whereas crude adulterants, such as alcohol, turpentine oil, petroleum, cinnamon oil, etc., may be detected with comparative readiness, the addition of clove stem oil cannot well be proved, though the nasal expert may suspect its presence. Shaken with hot water, the oil should not impart to the aqueous solution an acid reaction (probably cinnamic acid), nor should the presence of phenol in the filtered solution be indicated by ferric chloride.

Although clove stem oil contains more free eugenol than oil of cloves, the latter is commonly valued according to its eugenol content. The Pharmacopœia directs the following method of assay: Introduce into a narrow graduated cylinder 10 Cc. of the oil of cloves and 100 Cc. of potassium hydroxide test-solution, shake the liquids together for five minutes. When the fluids have separated completely, note the volume of the residual oil, which should not measure more than 2 Cc., indicating the presence of at least 80 per cent. of eugenol. Inasmuch as the non-phenol constituents of the oil are soluble in the aqueous solution of alkali phenylate, a mere shaking of the oil in a graduated cylinder with aqueous alkali yields too high results. Crude adulterations with petroleum and turpentine oil may, however, be indicated in this way, but not the addition of alcohol or carbolic acid.

Better quantitative results are obtained by Thom's method,[1] according to which eugenol is converted into its solid benzoic ester and weighed.

Action and Uses.—Oil of cloves is employed internally as a stimulant and carminative. It may be locally applied as a parasiticide, counterirritant, and anæsthetic. It is given internally to overcome flatulence and to prevent griping. This remedy has also been employed for the purpose of allaying the cough and decreasing the expectoration in pulmonary tuberculosis. For the latter condition it is employed both hypodermatically and by the mouth. It has been locally applied for the purpose of destroying parasites, such as *Pediculus pubis;* and when introduced into the cavity of an aching tooth frequently relieves the pain. Because of its counterirritant properties, it is frequently added to liniments and employed in the treatment of muscular rheumatism. The dose is from 2 to 5 minims (0.10–0.3 Cc.).

OLEUM CHENOPODII, *U. S.*—Oil of Chenopodium.

Oil of American wormseed, E.; *Essence de chénopode anthelmintique*, Fr.; *Chenopodiumöl, Americanisches Wurmsamenöl*, G.

Oil of chenopodium is a volatile oil distilled from the fruit of *Chenopodium ambrosioides* L., var. *anthelminticum* Gray (Fam. *Chenopodiaceæ*).

[1] The Volatile Oils, by Gildemeister, Hoffmann and Kremers, p. 516.

Oil of chenopodium has always been official in the U. S. P., but does not appear to have received official recognition elsewhere.

Most of this oil is distilled in Maryland, and since Baltimore is the commercial centre of that state, this oil is commonly known as Baltimore oil in distinction from western (Missouri) oil, which has at times played a rôle in the market.

Properties.—Oil of wormseed is colorless or yellowish, has a peculiar, penetrating, somewhat camphoraceous odor, and a pungent, bitter taste. Its specific gravity is about 0.965–0.985 at 25° C. (77° F.). It should be soluble in 5 volumes of 70 per cent. alcohol. The oil is lævogyrate; its angle of rotation should not exceed — 5° in a 100 Mm. tube at 25° C. (77° F.).—U. S.

Composition.—Garrigues (1854) obtained a terpene (probably pinene) and a fraction $C_{10}H_{16}O$. The property of recent commercial oil to decompose with explosive violence when distilled renders these claims doubtful.

Action and Uses.—Oil of chenopodium is employed for the expulsion of round worms. The dose for a child is from 5 to 10 minims (0.3–0.6 Cc.), twice daily for 3 or 4 days, after which an active purgative should be given. The oil has been recommended in the treatment of malaria, chorea, hysteria, and other nervous diseases, but is of little benefit in such conditions.

OLEUM CINNAMOMI, *U. S.*, *Br.*, *P. G.*—Oil of Cinnamon.

Oleum cinnamomi cassiæ. Oil of cassia, Oil of Chinese cinnamon, E.; *Essence de cannelle de Chine*, Fr.; *Zimmtöl, Zimmtkassienöl*, G.

A volatile oil distilled from Cinnamomum Cassia (Fam. *Lauraceæ*), yielding, when assayed by the process given below, not less than 75 per cent., by volume, of cinnamic aldehyde.—U. S.

By the above title different articles are designated. While the Br. P. calls for the oil of Ceylon cinnamon, the U. S. P. and the P. G. refer to the oil from the cheaper Chinese cinnamon or cassia. Inasmuch as cinnamic aldehyde is quantitatively the principal constituent of both oils, the U. S. P. of 1880 admitted both oils under the above designation. The result was, no doubt, that the cheaper oil took the place of the more expensive kind, and in 1890 oil of cassia was made official exclusively. The 1900 Pharmacopœia having admitted cinnamic aldehyde, the principal constituent of oil of cassia, it seems a pity that the latter was not dropped and in its stead the oil of Ceylon cinnamon introduced on account of its very much finer flavor. The descriptions of the U. S. P. and the P. G., therefore, stand for the same oil, namely, oil of cassia, whereas that of the Br. P. stands for the more fragrant oil of Ceylon cinnamon.

For the distillation of oil of cassia the leaves, with possibly some waste from the bark, are chiefly used. The commercial cassia oil, therefore, is not the oil demanded by the U. S. P. or by the P. G., according to their definitions. Moreover, in China cassia oil is distilled over a free flame, so that the commercial oil never has the aldehyde content obtained from the same material by steam distillation. Oil of Ceylon cinnamon is chiefly obtained from the waste that results from the peeling of the bark, commonly designated as "chips," the yield being about 0.5–1 per cent. The oil from Ceylon is reported frequently to contain leaf oil as well.

Properties.—Oil of cassia is a yellowish or brownish liquid, becoming darker and thicker by age and exposure to the air, having the characteristic odor of cinnamon, and a sweetish, spicy, and burning taste. Its specific gravity ranges from 1.045 to 1.055 at 25° C. (77° F.). The oil (or if it be dark, its distillate) should be optically almost inactive; it should not be more than 1 degree dextrogyrate or lævogyrate when viewed through a 100 Mm. tube. It is soluble in 2 volumes of 70 per cent. alcohol, and when shaken with a saturated solution of sodium bisulphite, it solidifies to a crystalline mass. If 4 drops of oil of cassia, contained in a test-tube, be cooled to 0° C. (32° F.) and then shaken with 4 drops of fuming nitric acid, crystalline needles or plates will be formed. —U. S.

Oil of Ceylon cinnamon is a yellow liquid when freshly distilled, but gradually becomes reddish, and has the agreeable, delicate odor of the bark, also the characteristic taste of the latter. The specific gravity varies from 1.025 to 1.035 at 15.5° C. (60° F.) —Br. The oil is slightly lævorotatory, up to —1° in a 100 Mm. tube, and is soluble in 3 parts of 70 per cent. alcohol.

Oil of cinnamon leaf is of light color, rather mobile, and has a mixed odor of cloves and cinnamon. Its specific gravity is higher than that of the preceding oils, ranging from 1.044 to 1.065 at 15° C. (59° F.). The oil yields a clear solution with 3 times its volume of 70 per cent. alcohol.

Composition.—The chief constituent of oil of cassia is cinnamic aldehyde (which see under CINNALDEHYDUM), of which from 70 to 80 per cent. and over is present, and next in importance is cinnamyl acetate, a liquid of extremely unpleasant acrid taste. Besides these, phenylpropyl acetate, orthocumaric aldehyde, and cinnamic acid are met with.

Oil of Ceylon cinnamon owes its value chiefly also to cinnamic aldehyde, of which, however, rarely more than 65 to 70 per cent. is present. Eugenol is an invariable constituent, as much as 8 per cent. having been found. In addition, the presence of phellandrene and other bodies has been reported. The particular cause of the fragrant aroma has not yet been discovered, and it is probably due to a combination of several constituents.

Cinnamon-leaf oil contains but a small proportion of cinnamic aldehyde, but is rich in eugenol (70 to 90 per cent.). Safrol, benzaldehyde, benzoic acid, and terpenes are also present.

Adulterations and Tests.—Oil of cassia has been frequently and grossly adulterated with a mixture of petroleum and rosin. The U. S. P. gives the following test for their detection: If 1 Cc. of the oil be mixed with 3 Cc. of a mixture of 3 volumes of alcohol and 1 volume of water, a clear solution should result; and if to this solution there be added gradually 2 Cc. of a saturated solution of lead acetate in a mixture of 3 volumes of alcohol and 1 volume of water, no precipitate should be produced (absence of petroleum and of rosin). If a portion of oil of cassia be shaken with hydrogen sulphide test-solution, it should not assume a dark color (absence of lead and copper).—U. S. A drop of ferric chloride solution added to a solution of 4 drops of oil of cassia in 10 Cc. of alcohol should not cause a green or blue coloration (absence of eugenol).—P. G. The Br. P. directs the following test for detection of cinnamon-leaf oil in oil of Ceylon cinnamon: The addition of ferric chloride test-solution to a solution of 1 Cc. of oil in 5 Cc. of alcohol should afford a pale-green, but not a decided blue coloration.

The requirements for a definite cinnamic aldehyde content vary for different pharmacopœias, thus: The U. S. P. demands not less than 75 per cent., the P. G. not less than 70 per cent., and the Br. P. at least 50 per cent.

For the assay a special flask (cassia flask, aldehyde flask) of about 100 Cc. capacity is used. The neck of the flask is about 13 Cm. long, has an inner diameter of 8 Mm., and is calibrated into $\frac{1}{10}$ Cc. The neck has a capacity of about 6 Cc. The zero mark is fixed slightly above the point where the flask is narrowed into the neck.

Assay for Cinnamic Aldehyde.—Introduce into a cassia flask, by means of a measuring-pipette, 10 Cc. of the oil of cinnamon, add 10 Cc. of a 30 per cent. solution of sodium bisulphite, shake the flask, and heat it in a water-bath containing boiling water until the contents are liquefied; add successive portions (10 Cc. each) of the bisulphite solution, shaking and heating as before, after each addition, until the flask is three-fourths filled. Continue to heat in the water-bath until the odor of cinnamic aldehyde is no longer perceptible, cool the flask to about 25° C. (77° F.), add enough of the bisulphite solution to raise the lower limit of the oily layer to the zero mark of the scale. The residual liquid should not measure more than 2.5 Cc., corresponding to at least 75 per cent. of cinnamic aldehyde by volume.—U. S.

Accurately speaking, percentage by volume and not percentage by weight is determined in this manner. Inasmuch, however, as the specific gravity of the aldehyde and the non-aldehyde constituents is almost the same, the two are practically identical.

The chemical reactions involved can be explained by means of the following equations; at first the insoluble aldehyde addition-product is formed:

$$\underset{\text{Cinnamic aldehyde.}}{C_6H_5.CH{:}CH.CHO} + \underset{\text{Acid sulphite of sodium.}}{NaHSO_3} = \underset{\text{Cinnamal hydroxy sulphonate of sodium.}}{C_6H_5.CH{:}CH.CHO.NaHSO_3}$$

When boiled with water, two molecules of this addition-product break up into a molecule of cinnamic aldehyde and one of sulpho-cinnamal hydroxy sulphonate of sodium.

$$\underset{\text{Cinnamal hydroxy sulphonate of sodium.}}{2C_6H_5.CH{:}CH.CHO.NaHSO_3} = \underset{\text{Cinnamic aldehyde.}}{C_6H_5.CH.CH.CHO} +$$

$$\underset{\text{Sulpho-cinnamal hydroxy sulphonate of sodium.}}{C_6H_5CH_2.CH(SO_3Na).CHO.NaHSO_3}$$

In order to convert all of the aldehyde into the second compound soluble in water it is necessary to use an excess (2 molecules) of sodium acid sulphite. The salts of the sulpho-cinnamal hydroxysulphonic acid are readily soluble in water and not decomposed by boiling water. They are decomposed by destructive distillation or when heated with caustic soda or sulphuric acid.

Action and Uses.—Oil of cinnamon is usually employed as an adjuvant to other remedies. It prevents the griping of drastic drugs, aids in the absorption of medicines, and disguises their taste. It has been recommended in atony of the stomach, flatulent colic, and uterine hemorrhage. The dose is from 1 to 3 minims (0.05–0.20 Cc.).

OLEUM COCOIS.—Coconut Oil.

Oleum Cocos.—Cocoanut butter, Cocoanut oil, E.; *Beurre de coco,* Fr.; *Kokosnussöl, Kokosöl, Kokosbutter,* G.

A mixture of liquid and solid fats, obtained from the fruit of the coco-palm, *Cocos nucifera* L. (Fam. *Palmaceæ*).

The coco-palm tree is now met with in all tropical countries, growing to a height of from 50 to 100 feet. It has at the apex a tuft of leaves, which are 3.6 M. (12 Ft.) or more long, and have numerous narrow rigid and long leaflets. The yellowish-white flowers produce the well-known coconuts, often as many as 120 on a single tree, which in their unripe state contain a sweetish liquid. The kernels contain much oil, which is obtained by cold or hot expression, or by decoction of the crushed seed in water. The kernels of *Cocos butyracea* L., of Brazil, yield a similar oil. Under the name *coprah,* the dried kernels are imported into Europe, where large quantities of the oil are expressed and known as *coprah oil.* Commercially the Cochin oil, prepared in Cochin (Malabar), ranks first, after which the Ceylon oil comes next, and the East Indian oil last.

Properties.—The best quality of coconut oil occurs as a white to pearl-white fat of the consistence of lard, and has a peculiar quite characteristic odor and taste. Ordinarily on exposure to the air it becomes rancid and acquires an acrid taste. The refined oil (treated with alcohol and animal charcoal, Schlich's process) remains sweet for a considerable time.

The melting-point of coconut oil varies from 22° to 28° C. (71.6°–82.4° F.) and congeals at 18°–12° C. (64.4°–53.6° F.). The cold-pressed oil melts at 20° C. (68° F.) and congeals at 13°–12° C. (55.4°–53.6° F.). After having been heated to 240° C. (464° F.) it remains liquid for several days. It is quite soluble in alcohol, 2 parts of 90 per cent. at 60° C., and very soluble in ether, chloroform, and carbon disulphide. It is characterized by its Reichert value 2.5 to 3.7, by its high saponification number (258), by the low iodine value 8 to 9.5, and the melting- (24.6°–27° C.) and congealing- (15°–20° C.) points of the fatty acids. These data distinguish it from butter, lard, and similar fats. It saponifies readily, the soap being capable of holding 40 to 60 per cent. of water, and is not easily precipitated by salt brine, whence its use as a "marine soap."

Composition.—Coconut oil contains chiefly trilaurin and trimyristin, besides triolein and a considerable percentage of the glycerides of capric, caproic, and caprylic acids. By cold pressure the solid fats may readily be separated from the liquid.

Action and Uses.—Coconut oil was employed formerly as a substitute for codliver oil. It is quite palatable, easily digested, and not prone to disorder the stomach. The dose is 4 fluidrachms (16 Cc.). It is used quite largely in the manufacture of soap, and to some extent is substituted for lard in the preparation of ointments.

Coconut oil in recent years in a refined condition (freed from free fatty acids) is used as a substitute for butter, being known as "Mannheim coconut butter," "Vegetable butter," "Vegetaline," "Lactine," "Laureol," "Nucoline," etc.

The exportations of coconut oil from Ceylon have amounted to 16,500 tons per annum; from British India, 6600 tons; from Dutch Indies, 1430 tons; while the total exportation of *coprah* from Ceylon, Samoa, Singapore, and Tahiti have amounted to 17,600 tons per annum.

OLEUM COPAIBÆ, *U. S., Br.*—Oil of Copaiba.

Oleum balsami copaivæ.—Essence de copahu, Fr.; *Copaivaöl,* G.

A volatile oil distilled from Copaiba.

Copaiba is distinguished according to the ports of export. The Para variety, which

yields 60 to 90 per cent. of oil, is for this reason preferred for distillation. Maracaibo and Maranhão copaibas yield about 40 per cent.

Properties.—Oil from Para and Maracaibo copaibas is a colorless, yellowish or bluish liquid possessing the characteristic pepper-like odor of the oleoresins, and a bitter, acrid, and persistent taste. The specific gravity, according to the U. S. P., may vary between 0.895 and 0.905 at 25° C. (77° F.); according to the Br. P., between 0.900 and 0.910. Its angle of rotation varies from —7 to —35°. Equal parts of absolute alcohol will usually effect solution, but the oil is not completely soluble in 90 per cent. alcohol. The Pharmacopœia states that oil of copaiba is soluble in 2 volumes of alcohol.

Composition.—The only known constituent of copaiba oil is the sesquiterpene caryophyllene.

Adulteration.—Copaiba oil is more frequently used as an adulterant than adulterated itself. As an adulterant Gurjun balsam oil, however, comes into consideration. This is indicated by its higher specific gravity (0.915–0.930) and by its greater angle of rotation (—35° to —130°). However, whereas most Gurjun balsam oils are lævogyrate, dextrogyrate oils have also been observed. Oil from African copaiba has a specific gravity of 0.917–0.918, and an angle of rotation equal to +20°; and is not soluble in an equal volume of absolute alcohol.

Action and Uses.—The action and uses of oil of copaiba are identical with those of COPAIBA (which see). The dose is from 5 to 10 minims (0.3–0.6 Cc.).

OLEUM CORIANDRI, *U. S.*, *Br.*—Oil of Coriander.

Essence de coriandre, Fr.; *Corianderöl*, G.

A volatile oil distilled from Coriander.

Coriander oil is distilled from the fruit which has been crushed between rollers. For the distillation on a large scale, the coriander from Moravia, Thuringia, and Russia is almost exclusively used, the yield being 0.8–1.0 per cent.

Properties.—Coriander oil is colorless or slightly yellowish, and possesses a characteristic coriander-like odor and an aromatic mild taste. Specific gravity, according to the U. S. P., is 0.863–0.878 at 25° C. (77° F.); according to the Br. P., 0.870–0.885 at 15.5° C. (60° F.). Its angle of rotation varies from +8° to +13°. The oil is soluble in 3 parts of 70 per cent. alcohol; also soluble in all proportions in 80 and 90 per cent. alcohol.—U. S.

Constituents.—The oil consists of about 90 per cent. of dextrogyrate linalool, formerly designated coriandrol, about 5 per cent. of *d*-pinene, and other unknown substances which impart to the oil its peculiar aroma.

Adulteration.—Turpentine oil, cedarwood oil, and sweet orange oil are indicated by their lesser solubility in 70 per cent. alcohol. Oil of cubebs is also mentioned as having been used occasionally.

Action and Uses.—Oil of coriander, like the fruit from which it is obtained, is employed in the treatment of flatulent colic, and to prevent the griping and mask the taste of other remedies. It is also said to relieve the pain of muscular rheumatism and neuralgia. The dose is from 1 to 5 minims (0.05–0.3 Cc.).

OLEUM CUBEBÆ, *U. S.*, *Br.*—Oil of Cubeb.

Oleum cubebarum.—Oil of cubebs, E.; *Essence de cubèbe*, Fr.; *Cubebenöl*, G.

A volatile oil distilled from cubeb.

Comminuted cubebs upon distillation with water vapor yield 10–18 per cent. of oil.

Properties.—Cubeb oil is a viscid colorless, light-green or greenish-yellow liquid. The last portions of the distillate being blue may render the otherwise yellowish oil colorless. It possesses the characteristic cubeb odor and a warm, camphor-like taste, which finally becomes acrid. Specific gravity 0.905–0.925 at 25° C. (77° F.).—U. S. Its angle of rotation varies from —25° to —40°. Its solubility in 70 per cent. alcohol varies greatly. Some oils, presumably from old cubebs, are soluble in an equal part, others require 10 parts to effect solution.

Composition.—The bulk of the oil consists of sesquiterpenes, cadinene, and a second one which has not yet been identified. Small amounts of terpenes, namely, dipentene, and probably pinene and camphene, are also present. Whereas oil from fresh cubebs

appears to consist almost entirely of hydrocarbons, the oil from old berries has been found to contain cubeb camphor, a sesquiterpene hydrate. This hydrate is supposed to be formed by the action of the moisture of the atmosphere on the sesquiterpene in the berries.

Action and Uses.—The properties of oil of cubeb are analogous to those of CUBEBA (which see). It is probably less efficient than the powdered drug, but may be substituted for the latter in doses of from 10 to 15 minims (0.6–1 Cc.).

OLEUM ERIGERONTIS, *U. S.*—Oil of Erigeron.

Oleum erigerontis canadensis.—Oil of fleabane, E.; *Essence d'erigeron*, Fr.; *Erigeronöl*, G.

A volatile oil distilled from the fresh flowering herb of *Leptilon Canadense* (L.) Britton.—(Fam. *Compositæ*).

Fleabane, horseweed or butterweed, is a common American weed, frequently found in peppermint fields. The fresh herb yields upon distillation 0.2–0.4 per cent. of oil, which finds limited medical application in the United States and which was made official in the U. S. P. of 1890.

Properties.—When fresh, erigeron oil is a colorless or light-yellow, mobile liquid. Exposed to the air it rapidly resinifies, becoming viscid and darker. It has a peculiar, aromatic, persistent odor, and an aromatic, slightly pungent taste. Its specific gravity ranges from 0.845–0.865 at 25° C. (77° F.); its angle of rotation equals about +50°. With an equal volume of 94 per cent. alcohol it forms a clear solution (distinction from oil of fireweed and oil of turpentine).—U. S.

Composition.—The bulk of erigeron oil consists of *d*-limonene. Terpineol has also been obtained from the oil, but whether this exists as such in the oil or whether it is a product of decomposition, due to the heat applied during fractional distillation, remains undetermined.

Action and Uses.—Oil of erigeron has been employed successfully in the treatment of oozing hemorrhages from the uterus, epistaxis, and other passive hemorrhages. It has been recommended also for hemorrhage of the intestines in enteric fever, and is said to do good in diarrhœa and dysentery. It may be employed as a substitute for the oils of cubeb and copaiba in the treatment of gonorrhœa. The dose is from 10 to 30 minims (0.6–2 Cc.), which amount may be repeated in from 2 to 4 hours.

OLEUM EUCALYPTI, *U. S., Br.*—Oil of Eucalyptus.

Oil of eucalyptus globulus, E.; *Essence d'eucalyptus*, Fr.; *Eucalyptusöl*, G.

The volatile oil distilled from the fresh leaves of *Eucalyptus*, and rectified by steam distillation, yielding, when assayed by the process given below, not less than 50 per cent. of cineol (eucalyptol).—U. S.

According to Hirsch, eucalyptus oil is official in the following pharmacopœias: Belg., Br., Gall., Hung., Japon., Norv., Rom., U. S. In the U. S. P. it has been official since the 1880 edition. Though not official in the P. G. IV., it has been adopted in the "Arzneimittel, etc.," which is commonly regarded as a supplement.

Like the U. S. P. of 1880, the Br. P. admits the oil of other species; the P. G., Suppl. II., however, admits the oil from the one species only.

Since the cultivation of eucalyptus and the distillation of eucalyptus oils have been established on so scientific a foundation by the efforts of the Technological Museum of Sydney, N. S. W., there is no excuse for an indiscriminate definition.

According to their chemical composition, the numerous eucalyptus oils have been classified into the following groups:

I. Cineol-containing oils.
II. Citronellal-containing oils.
III. Citral-containing oils.
IV. Oils with a peppermint-like odor.
V. Oils less known and of indefinite odor.

Inasmuch as cineol or eucalyptol is generally regarded as the constituent of prime medicinal value, the first group alone need receive consideration. Of this group possibly only those oils enumerated in the table below may be regarded as probable substitutes for *E. globulus* oil because they meet the twofold requirement of containing a fair amount of cineol and being distilled in sufficient quantity to be of commercial importance.

Owing to the rapid growth of the trees of this genus it is impossible to deny future commercial importance to any of these and possibly others.

Although the genus *Eucalyptus* has possibly been more systematically studied for its oils than any other genus, the knowledge which we possess of individual oils is insufficient and sometimes uncertain. The following table will give some idea of the present chemical knowledge of the medicinally more important oils:

	Constituents.				
E. globulus	Cineol	*d*-Pinene	Eudesmol[1]	. . .	. . .
	(and possibly camphene, butyric, valeric, and capronic aldehydes, also fatty acids and ethyl and amyl alcohols).				
E. odorata	Cineol	Pinene	. . .	Aromadendral[2]	. . .
E. cneorifolia	Cineol	Pinene	. . .	Aromadendral	. . .
E. oleosa	Cineol	Pinene	. . .	Aromadendral	Sesquiterpene
E. dumosa	Cineol	Pinene	. . .	Aromadendral	. . .
E. amygdalina	Cineol	Pinene	Eudesmol	. . .	. . .
	(phellandrene, peppermint, ketone, methyl, ethyl, isobutyl, and amyl alcohols).				

The above tabulation shows the known differences between the oils of *E. globulus* and *E. amygdalina* on the one hand and of the four remaining oils on the other hand. It also shows that the oil of *E. amygdalina* contains phellandrene, a hydrocarbon found extensively in oils containing but little or no cineol. Baker and Smith state that "by a proper system of distillation and rectification an oil containing 35 to 40 per cent. of eucalyptol can be obtained from this species."

In this connection attention ought to be called to the necessity of rectifying eucalyptus oil so as to remove obnoxious aldehydes, etc., since they make themselves unpleasantly noticeable in the crude oil by their tendency to produce coughing.

The oil of *E. globulus* is the most valued of all the medicinal eucalyptus oils of commerce, not only because of its high cineol content, but also because it has been characterized by a constancy of constituents and general characters mostly wanting in the commercial oils from the other species.

E. odorata yields but a small amount of oil which at times has been found rich in cineol, but according to the Australian authorities contains only 20–25 per cent.

The oil of *E. cneorifolia*, containing as much as 50–75 per cent. of cineol, is stated to conform to the requirements of the British Pharmacopœia, but it contains cuminic aldehyde and, owing to the comparatively large amount of high boiling constituents, is a somewhat heavy oil.

The oils of *E. oleosa* and *E. dumosa* are fairly rich in cineol.

E. amygdalina yields over 3 per cent. of oil. Formerly it came into the market in great quantities, but has recently been displaced by oils richer in cineol. Whereas at one time this oil was much esteemed on account of its low cineol content, it has fallen into disfavor and now commands a very low price.

Properties.—Oil of eucalyptus, when rectified for the purpose of removing objectionable aldehydes, is colorless. It has an aromatic camphoraceous odor, and a pungent, spicy, and cooling taste. Specific gravity 0.905–0.925 at 25° C. (77° F.); angle of rotation varies from +1° to +15°; according to the U. S. P. it should not be more than +10°. The Br. P. limits the rotation to not more than 10° in either direction in a 100 Mm. tube. When exposed to a mixture of ice and salt, oils rich in cineol congeal to a white crystalline mass.

In the following table are the specific gravities of the principal cineol-containing oils as recorded by the authorities mentioned:—

	B. et S.	G.-H.-K.	Parry.	C.-D.-P.
E. globulus	0.9130	0.910–0.930	0.910–0.930	0.910–0.930
E. odorata	0.9042	0.899–0.925	0.900–0.925	0.907
E. cneorifolia	0.9287	0.899–0.923	0.915–0.925	. . .
E. oleosa	0.9250	0.906–0.926	. . .	. . .
E. dumosa	0.9016–0.9151	0.844–0.915	0.900–0.912	. . .
E. amygdalina	0.9012–0.9050	0.850–0.886	0.855–0.890	0.874–0.897

The specific gravity of eucalyptol is 0.930, whereas that of phellandrene, according to Wallach, is 0.8465 at 19° C. There are, however, other constituents than cineol that tend to increase the specific gravity of the oil.

[1] A substance, $C_{10}H_{16}O$, possibly a ketone, m. p. 79-80° C.
[2] An aldehyde, $C_{10}H_{14}O$, resembling cumin aldehyde in odor.

The U. S. P. states that oil of eucalyptus is soluble in all proportions of alcohol and in 3 volumes of 70 per cent. alcohol. The Br. P. does not give a solubility test in alcohol. The following solubility constants are recorded by the several authorities mentioned:—

	B. et S.	G.-H.-K.	Parry.
E. globulus	1½ volumes 70 per cent.	3 volumes 70 per cent.	. . .
E. odorata	1 volume 80 per cent.	. . .	. . .
E. cneorifolia	1½ volumes 70 per cent.	. . .	. . .
E. oleosa	1¼ volumes 70 per cent.	. . .	. . .
E. dumosa	1¾ volumes 70 per cent.	. . .	. . .
E. amygdalina	1¼ to 2 vols. 70 per cent.	6 volumes 90 per cent.	. . .

The following table records the angle of rotation, $(\alpha)_D$, as given by different authorities:—

	B. et S.	G.-H.-K.	Parry.	G.-D.-P.
E. globulus	+9.2°	+ 1° to +15°	+ 1° to +10° (rarely up to 15°)	+ 1° to + 20°
E. odorata	+2.43°	slightly l.	. . .	. . .
E. cneorifolia	—5.82°	—4° to —14°	±4° to ±5°	. . .
E. oleosa	—1.62°	+4° to +5°	. . .	. . .
E. dumosa	+2.44° to +6.34°	+6°6′ to +6°30′	. . .	. . .
E. amygdalina	—11.37° to —13.53°	—25° to —70°	—25° to —80°	—24° to —120° —27° to —68°

The more cineol an oil contains, . . . the lower its rotatory power. Cineol is optically inactive, whereas phellandrene exists in two varieties, viz., dextrogyrate and lævogyrate.

Cineol, the principal constituent of medicinal import, boils at 177° C. and pinene at 155°–156° C. Eudesmol melts at 79°–80° C. and sublimes at 100° C. Phellandrene, quantitatively the principal constituent of oils poorer in cineol, boils at 171°–172° C.

Cineol Assay.—The phosphoric acid method apparently gives fairly satisfactory results for a commercial assay. The following are the official directions: "Introduce into a beaker a solution prepared by dissolving 10 Cc. of oil of eucalyptus in 50 Cc. of purified petroleum benzin; immerse the beaker in a freezing mixture and add phosphoric acid, drop by drop, with constant stirring, until the white magma of cineol phosphate formed begins to assume a yellowish or pinkish tint; then transfer the magma to a force filter, wash it with cold purified petroleum benzin, and then dry it by pressure between two porous plates. Transfer the precipitate (cineol phosphate) to a narrow graduated cylinder, and add warm water, which will cause separation of the cineol. The volume, in cubic centimeters, of the separated oil, multiplied by 10, represents the volume per cent. of cineol (eucalyptol). This should correspond to the properties and tests given under EUCALYPTOL."—U. S.

Test for Phellandrene.—If 2 Cc. of the oil be mixed with 4 Cc. of glacial acetic acid, and 3 Cc. of a saturated aqueous solution of sodium nitrite be gradually added, the mixture, when gently stirred, should not form crystals of phellandrene nitrite (absence of eucalyptus oils containing much phellandrene).—U. S. According to F. B. Power the reaction can be made more delicate by mixing the oil first with 5 Cc. of petroleum benzin, then adding the sodium nitrite solution, and lastly the glacial acetic acid, drop by drop, with vigorous agitation after each addition. If the oil be rich in phellandrene, the entire liquid solidifies to a pasty mass.

Action and Uses.—The properties of this oil are fully described under EUCALYPTUS (which see). The dose is from 1 to 5 minims (0.05–0.3 Cc.).

OLEUM FŒNICULI, *U. S., P. G.*—Oil of Fennel.

Essence de fenouil, Fr.; *Fenchelöl*, G.

Oleum fœniculi is the volatile oil distilled from Fennel.

Oil of fennel is official in all pharmacopœias except the British and the Italian.

The fruit of the fennel cultivated in various countries differs not only externally but also in the quantity and character of oil it yields upon distillation. The yield from the principal varieties, namely, the Saxon (Lützen), Galician, Moravian, and Roumanian, varies from 4 to 6.5 per cent. The lower yield of other varieties, no doubt, accounts in part for their non-use. Besides this difference in yield, there are likewise differences in composition.

Properties.—At medium temperatures oil of fennel is a colorless or slightly yellow liquid possessing the odor of fennel and a taste which, though at first bitter and cam-

phor-like, is afterward sweet. According to the U. S. P., its specific gravity ranges from 0.953–0.973 at 25° C. (77° F.); according to the P. G., between 0.965 and 0.975; its angle of rotation varies from +12° to +24°. The congealing-point of a normal fennel oil lies between +3° and +6° C. It is soluble in an equal volume of alcohol, the solution being neutral to litmus-paper, and in 10 volumes or less of 80 per cent. alcohol.—U. S.

Composition.—The constituent on which the value of this oil is supposed largely to depend is anethol, which crystallizes out in the cold. The oil also contains an isomer of this phenol ether, viz., chavicol; further, fenchone, an isomer of camphor and closely related to it; anise ketone; and, like all anethol-containing oils, anisic aldehyde and anisic acid. Of hydrocarbons, the presence of *d*-pinene and dipentene has been proved. Cymene and phellandrene are possibly also present.

While the four varieties of fennel mentioned above and the Japanese are distinguished by the bitter-tasting fenchone, this ketone is not found in the sweet Roman (French) and Macedonian fennel. Anethol, on the other hand, is either entirely absent or present only in traces in the wild bitter fennel.

As to hydrocarbons, the Saxon oil contains pinene and dipentene, the wild bitter fennel oil phellandrene, and Macedonian fennel oil limonene.

Under fennel oil there may be understood, therefore, in different countries different products. Oil of fennel of the U. S. P. and P. G. is the oil obtained from the commercial varieties of *Fœniculum capillaceum*, mentioned above.

Examination.—Whereas most authorities agree that the value of a fennel oil can be estimated by its anethol content, 50–60 per cent., some claim that the methyl ether content, viz., anethol plus its isomer methyl chavicol = 60 to 70 per cent., should be used for assay purposes. However, the congealing-point, which is characteristic of the anethol content, is commonly used as the test. It is fixed by the U. S. P. at not below 5° C. (41° F.), to be determined as follows: Transfer about 10 Cc. of the oil to a test-tube placed in a freezing mixture; insert a thermometer at once into the oil, and allow it to remain undisturbed until its temperature has fallen to about —5° C. (23° F.). Induce crystallization either by scratching the inner-wall of the test-tube with the thermometer or by the addition of a particle of solid anethol, and stir continuously during the solidification of the oil. The highest temperature reached during the crystallization is regarded as the congealing-point.

Besides the ordinary adulterants, oil of fennel is sophisticated by the abstraction of anethol. The addition of turpentine oil or of oils deprived of anethol will be indicated by a lower congealing-point, as well as the partial abstraction of anethol from an oil otherwise not tampered with.

Action and Uses.—Oil of fennel may be employed to overcome flatulence and to mitigate the action of severe purges. It is thought to possess emmenagogue and galactagogue properties. The dose is from 5 to 15 minims (0.3–1 Cc.).

OLEUM GAULTHERIÆ, *U. S.*—Oil of Gaultheria.

Oil of wintergreen, E.; *Essence de gaulthérie*, Fr.; *Wintergrünöl, Bergtheeöl*, G.

Oil of gaultheria is the volatile oil distilled from the leaves of *Gaultheria procumbens* L.—(Fam. *Ericaceæ*), rectified, if necessary, by steam distillation.—U. S.

True wintergreen oil, of which but a small amount is produced, is distilled mostly in a primitive manner by farmers in the mountainous districts of New York, New Jersey, Pennsylvania, Virginia, and Maryland. The oil exists in the plant not as such, but evidently in the form of a glucoside, which must be hydrolyzed before distillation. Sweet birch bark is often distilled with wintergreen leaves. Compare oil of sweet birch, which is commonly designated as "natural oil of wintergreen" in the market.

Properties.—Owing to the primitive methods of distillation, crude wintergreen oil is commonly colored red, but loses its color upon rectification. The oil, when properly prepared, is colorless or yellowish, and possesses a characteristic spicy odor in addition to that of methyl salicylate. Its specific gravity ranges from 1.172 to 1.180 at 25° C. (77° F.) and its boiling-point varies from 218° to 221° C. (424.4°–429.8° F.).—U. S. When fresh, it is slightly lævogyrate: the angle of rotation ranging from —0° 25′ to —1°. With 6 parts of 70 per cent. alcohol it yields a clear solution at 20° C. (68° F.).

Composition.—True wintergreen oil consists of about 99 per cent. of methyl salicylate. The composition of the 1 per cent. plus is rather complex, paraffin hydrocarbons, an aldehyde or ketone, an alcohol, $C_8H_{16}O$, corresponding to the aldehyde or

ketone, and an ester have been isolated. The ester consists of the above alcohol, $C_5H_{16}O$, and an acid, $C_6H_{10}O_2$, which likewise results upon the oxidation of the above ketone or aldehyde. The alcohol and the ester possess the very penetrating odor which characterizes the true wintergreen oil.

Tests.—While the expert may readily distinguish pure samples of gaultheria oil, sweet birch oil, and artificial methyl salicylate by the nasal test, it is impossible in this manner to detect the addition of sweet birch oil or methyl salicylate. Even after the methyl salicylate odor has been removed by the solution of the phenol ester in aqueous potassium hydroxide solution, it may be impossible to detect such additions by the nasal test. Inasmuch as all these products consist almost exclusively of methyl salicylate, their physical constants are very closely related. The lævorotation of gaultheria oil may at times be serviceable, but the angle is small at best, and varies considerably for its size. Moreover, true gaultheria oil may become optically inactive in the course of time.

In other respects it has the same properties and conforms to the reactions and tests given under METHYLIS SALICYLAS.

Action and Uses.—In medicinal doses, oil of wintergreen may be employed as a substitute for ACIDUM SALICYLICUM (which see). Like many other volatile oils, it may be used also as an antiseptic, analgesic, flavoring agent, and carminative. Added to liniments, it is quite largely employed in the treatment of muscular rheumatism, lumbago, sciatica, and similar complaints. The pure oil is locally applied upon lint over swollen joints in acute articular rheumatism, and is said to be efficacious also in the treatment of tic douloureux. In overdose it produces drowsiness, followed by cerebral congestion and delirium. Excessive gastric irritability, vomiting, purging, gastro-intestinal pain, rapid pulse, hot dry skin, and difficult respiration are the principal symptoms resulting from the administration of toxic doses of this drug. The poisonous effects of the remedy should be combated by rapidly acting diffusible stimulants, such as ether, alcohol, and ammonia. The beginning dose of the oil is from 5 to 10 minims (0.3–0.6 Cc.) every 4 hours. This amount may be increased, providing digestion is not impaired, until the full effect of the remedy is produced.

OLEUM GOSSYPII SEMINIS, *U. S.*—Cotton Seed Oil.

Oleum gossypii.—*Cotton oil*, E.; *Huile de coton, Huile de semences de cotonnier*, Fr.; *Baumwollsamenöl, Cottonöl*, G.

A fixed oil expressed from the seed of *Gossypium herbaceum* L. and of other species of *Gossypium* (Fam. *Malvaceæ*), and subsequently purified.—U. S.

Origin and Preparation.—(For remarks on the cotton-plant, see page 736.) After the seeds have been deprived of the cotton they are about 8 Mm. ($\frac{1}{3}$ In.) in length and 4 Mm. ($\frac{1}{6}$ In.) in width, of an irregular ovoid shape, have a brown, hard, somewhat brittle testa with a prominent raphe along its entire length, and contain a whitish embryo with large folded cotyledons and numerous blackish resin-glands imbedded in its tissue. For obtaining the oil the testa is crushed in a suitable machine and removed by winnowing; the kernels are then ground and, enclosed in bags, are subjected to hydraulic pressure. Raw cotton yields about 40 per cent. of seeds, which in turn produce 2 gallons of oil per bushel. 100 pounds of seeds yield on an average 14.5 pounds of oil, 44.5 pounds of hulls, 1 pound of lint, and 40 pounds of residuary oil-cake. Cottonseed oil-cake contains about 7.5 per cent. of oil and 20 per cent. of albuminoids.

Purification.—The crude oil is of a more or less deep-brown color, turbid, thickish, and contains a large percentage of albuminous matter. On standing, a portion of the impurities subside, and the oil, now termed "clarified," becomes clear and of an orange color. On treating it with boiling water or superheated steam the albuminous constituents are coagulated, and a still lighter colored oil is obtained. The final bleaching is effected by agitating the oil well with a weak solution of caustic soda, whereby the characteristic coloring-matter of the oil is removed and a black soapy deposit settles to the bottom. The loss by this process amounts to about 4 to 7 per cent., and sometimes to more than twice as much, and the resulting purified oil is known as *refined oil*.

Properties.—Bleached cottonseed oil is perfectly transparent, and has a reddish-yellow to pale straw-yellow color; it is without odor and has a bland, nut-like taste and

a neutral reaction. Its specific gravity varies from 0.920 to 0.926 at 15° C. (59° F.), or from 0.915 to 0.921 at 25° C. (77° F.). While readily soluble in ether, chloroform, benzene, and carbon disulphide, it is very sparingly soluble in alcohol. Exposed to the air, the oil gradually thickens, but does not solidify. On cooling the oil to a temperature below 12° C. (53.6° F.) particles of solid fat separate. At about 0° to —5° C. (32° to 23° F.) the oil becomes nearly or quite solid. If sulphuric acid of 1.6 to 1.7 specific gravity be added to the oil, preferably diluted by solution in carbon disulphide, a reddish-brown color is rapidly produced. If 6 Gm. of the oil be thoroughly shaken in a test-tube for about 10 minutes with a mixture of 1.5 Gm. of nitric acid and 0.5 Gm. of water, then heated on a boiling water-bath for not more than 15 minutes, the oil will assume an orange or reddish-brown color, and after standing for 12 hours at the ordinary temperature, will form a semisolid mass. If 5 Cc. of the oil be thoroughly shaken in a test-tube with 5 Cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 Cc. of alcohol and adding 2 drops of nitric acid), and the mixture heated for about 5 minutes on a water-bath, the oil will assume a red or reddish-brown color. If 2 Cc. of the oil be mixed in a test-tube with 2 Cc. of a mixture of amyl alcohol and carbon disulphide containing 1 per cent. of sulphur in solution, and the test-tube then immersed to the depth of one-third to one-half in boiling salt water, in from 10 to 15 minutes a red color will develop.—U. S. Nitric acid of 1.375 specific gravity gives a deep-brown coloration with cottonseed oil, but the reaction is not equally intense with all samples of the oil, the coloration being more or less vitiated if the oil has been heated above 240° C. (464° F.). The oil is readily saponified by strong solutions of alkali, with the exception of a bright-yellow coloring-matter, which may be obtained by agitating the soap with benzin.

Chemical Composition.—Cottonseed oil consists chiefly of olein, palmitin, and linolein, together with small quantities of the glyceride of linolenic acid. From that portion of the oil saponified in the bleaching process a pigment, known as cottonseed blue and stated by Kuhlmann (1861) to have the composition $C_{17}H_{24}O_4$, has been obtained by heating the soapy sediment with 4 per cent. of sulphuric acid for several hours to 100° C. (212° F.), washing with water, and dissolving in alcohol. This pigment is amorphous, readily destroyed by oxidizing agents, insoluble in water, diluted acids, and alkalies, sparingly soluble in chloroform and carbon disulphide, soluble in 77 parts of alcohol and in 8.4 parts of ether. It dissolves with a purple color in sulphuric acid and is bleached on exposure to light and air.

Tests.—Cottonseed oil saponified by alcoholic potassium hydroxide test-solution should show a saponification-value of from 191 to 196. If 0.3 Gm. of cottonseed oil be dissolved in 10 Cc. of chloroform, and placed in a 250 Cc. flask with 25 Cc. of a mixture of equal parts of alcoholic iodine test-solution and alcoholic mercuric chloride test-solution, and after standing for 4 hours protected from the light, 20 Cc. of potassium iodide test-solution be added, and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate solution an iodine figure of not less than 102 nor more than 108 should be obtained.—U. S. Cottonseed oil differs from all other fixed oils in the high melting-point, 32°–38° C. (89.6°–100.4° F.), and high congealing-point, 34°–27.5° C. (93.2°–81.5° F.), of its fatty acids.

For the detection of cottonseed oil in other oils the following tests may be applied:

Nitric Acid Test.—Equal volumes of oil and nitric acid of 1.375 specific gravity are shaken together and then set aside for 24 hours. Oils containing cottonseed oil assume a distinct brown coloration, whereas pure oils, as olive oil, rape oil, and others, show only a yellowish color (Lewkowitsch). This test is even available in the case of adulterated oils which have been heated to 240° C. (464° F.).

Halphen's Test.—Equal volumes of carbon disulphide holding 1 per cent. of sulphur in solution, amyl alcohol, and the suspected oil, are mixed and heated for 15 minutes in a boiling bath of brine. In the presence of cottonseed oil, an orange to deep-red coloration ensues. If the oil has been exposed to a temperature of 250° C. (482° F.) even for 10 minutes, the color-change does not occur, although a temperature of 210° C. (410° F.) is not hurtful. According to L. M. Tolman, if the cottonseed oil has been previously heated, as is frequently the case, the brine-bath should be kept at a temperature of 112° to 115° C. (233.6°–239° F.) for 1 or 2 hours to insure the proper color-reaction.

It is probable that the nitric acid and Halphen reactions depend upon the same constituent in the cottonseed oil, since it has been found that the previous application of the one test prevents the other reaction, after removal of either the nitric acid or amyl alcohol respectively. The substance causing the color-reaction has not been isolated.

Becchi's Test.—The following solutions are necessary: (*a*) 1 Gm. of silver nitrate dissolved in 200 Cc. of 98 per cent. alcohol, and then mixed with 40 Cc. of ether and 0.1 Gm. (1 drop) of nitric acid; (*b*) 15 Cc. of colza (rapeseed) oil dissolved in 100 Cc. of amyl alcohol.

10 Cc. of the suspected oil are mixed with 1 Cc. of the silver nitrate solution and 10 Cc. of the colza oil solution then added. After active agitation the mixture is divided into two parts, one of which is placed in boiling water for 15 minutes and then compared with the unheated portion. If cottonseed oil be present, the heated mixture becomes brown.

Becchi's test is not applicable to oils that have previously been heated to 200° C. (392° F.) or over. The test is made more delicate by first washing the oil to be tested with an equal volume of hot 95 per cent. alcohol, and after its removal, with dilute (2 per cent.) nitric acid, and then thoroughly with water. Its reliability has been questioned by several authorities, and modifications proposed with, however, unsatisfactory results.—Benedickt and Ulzer.

Uses.—Cottonseed oil is used by the U. S. P. for liniments in the place of olive oil. It has entered largely into consumption as an edible oil, salad oil, and as a constituent of oleomargarine and similar products. It is extensively used in soap-making, and very largely as a substitute and adulterant of more expensive oils.

The amount of cottonseed oil produced in the United States in 1901 amounted to 96,605,600 gallons, valued at over 30 million dollars. Of this quantity, 49,356,741 gallons were exported at a valuation of $16,541,321. Of the total by-product oil-cake produced in the United States, about one-fourth is consumed for fodder and fertilizers. The amount of oil-cake exported during the fiscal year 1901 was 629,343.6 tons, valued at $13,119,968.

OLEUM HEDEOMÆ, *U. S.*—Oil of Hedeoma.

Oil of pennyroyal, E.; *Essence de hedeoma, Essence de puliot américaine*, Fr.; *Pennyroyalöl, Amerikanisches Poleiöl*, G.

A volatile oil distilled from the leaves and flowering-tops of *Hedeoma pulegoides* (L.) Pers. (Fam. *Labiatæ*).

Most of the pennyroyal oil is reported as being distilled in North Carolina and in the southern and eastern sections of Ohio, often in rather primitive stills. This oil is closely related to the Oleum Pulegii of Europe obtained from *Mentha pulegium* L. or *Pulegium vulgare* Mill. A Russian oil is obtained from *Pulegium micranthum* Claus.

Properties.—American pennyroyal oil is a light-yellow liquid of a characteristic minty, sweetish odor, and an aromatic taste. Specific gravity 0.920 to 0.935 at 25° C. (77° F.); angle of rotation varies from +18° to +22°. It is soluble in two volumes of 70 per cent. alcohol, forming a clear solution.—U. S.

Composition.—The principal and only constituent known definitely to exist in the oil is pulegone, a ketone, $C_{10}H_{16}O$, which can be identified by its hydrated oxime.

Action and Uses.—Oil of pennyroyal possesses stimulant, carminative, and emmenagogue properties. Like other volatile oils, it may be employed as an adjuvant and corrective for other medicines. It has been used in the treatment of amenorrhœa. The dose is from 2 to 10 minims (0.10–0.60 Cc.).

OLEUM HYOSCYAMI COMPOSITUM.—Compound Oil of Hyoscyamus.

Balsamum Tranquillans.—Huile de jusquiame composée, Fr.; *Zusammengesetztes Bilsenkrautöl*, G.

Preparation.—Take of oil of absinthe, oil of lavender, oil of rosemary, oil of sage, oil of thyme, of each, 2 drops; infused oil of hyoscyamus, 100 Cc. Mix them.—N. F.

The infused oil of hyoscyamus, designated in the above formula, may be prepared by either of the methods given under Infused Oils, on page 1006.

This preparation is very similar to, but not identical with, the Baume Tranquille (Balsamum Tranquillans) of the French Pharmacopœia. The latter is made as follows:

200 Gm. each of the fresh leaves of belladonna, hyoscyamus, poppy, black nightshade, stramonium, and tobacco are crushed and digested with 5000 Gm. of olive oil over a gentle fire, until the moisture has been completely dissipated; the mixture is then expressed and the liquid filtered. To the clear liquid are finally added 0.50 Gm. each of the oils of absinthe, hyssop, marjoram, mint, rue, rosemary, sage, and thyme.

Action and Uses.—This preparation is employed chiefly as an anodyne in earache. A piece of cotton is saturated with a few drops of the oil and placed in the external auditory canal.

OLEUM JUNIPERI, *U. S., Br., P. G.*—Oil of Juniper.

Oleum fructus (vel baccæ) juniperi.—Oil of juniper berries, E.; *Essence de genièvre* Fr.; *Wachholderbeeröl*, G.

A volatile oil obtained by steam distillation from the fruit of *Juniperus communis* L. (Fam. *Coniferæ*). The oil obtained as a by-product in the manufacture of gin is not a normal oil, neither is that obtained from the young branches as well as the fruit (P. Norv.), nor the oil obtained from unripe fruits (Br.). To what extent, if any, the oil from the berries of *J. phœnicea* and *J. oxycedrus* enter commerce is not known. The former oil is said to correspond in all of its properties with those of the official oil, whereas the latter is quite terebinthinate in odor, reminding but faintly of juniper. The yield varies from 0.5 to 1.5 per cent.

Properties.—Juniper berry oil is colorless or faintly greenish-yellow when fresh. It possesses the characteristic odor of *juniper* and a warm, aromatic, somewhat terebinthinate and bitterish taste. With age, and especially when exposed to air and light, it becomes darker and thicker. Several pharmacopœias specify that such a modified oil should not be used for medicinal purposes.

According to the U. S. P., the specific gravity should vary within 0.860 to 0.880 at 25° C. (77° F.). The oil should be soluble in 10 volumes of 90 per cent. alcohol—most oils are soluble, but the solubility diminishes with age. As to its optical activity, statements are at variance.

Composition.—Oil of juniper contains pinene and cadinene, also "juniper comphor." The constituents imparting to the oil its characteristic odor are unknown. The amount of saponifiable substances is small and does not influence the odor. Neither is the amount of ester-forming alcohols much larger.

Adulteration.—The detection of turpentine oil is difficult, since it changes the physical constants of the oil but little, pinene being a regular constituent of the oil. (Compare also Norwegian oil above.)

Action and Uses.—Oil of juniper is a valuable antiseptic, carminative, and stimulant, and is especially useful in the treatment of dropsy depending upon chronic nephritis. It should not be employed, however, if any acute renal inflammation exists. It is usually administered in the form of Holland gin or compound spirit of juniper. The dose of the oil is from 5 to 15 minims (0.3–1 Cc.). As an antiseptic, it is largely employed for sterilizing catgut.

OLEUM LAURI, *P. G.*—Laurel Oil.

Oleum lauri expressum, Oleum laurinum.—Bayberry oil, E.; *Huile de laurier, Beurre de laurier*, Fr.; *Lorbeeröl, Lorbeerbutter, Lorbeerfett, Loröl, Lorettosalbe*, G.

Source.—Laurel oil is obtained from the crushed fresh or dried berries of the laurel tree, *Laurus nobilis* L. (Fam. *Lauraceæ*), by expression, with the aid of a gentle heat, between iron plates. After subsidence, the oil is decanted and if necessary filtered

Properties.—It occurs as a soft, at times granular, butter-like fat of green color, possessing a bitter taste and a peculiar aromatic odor. The oil is insoluble in alcohol, but yields to that liquid some of the bodies accompanying the fat. It is soluble in ether and benzene. At 40° C. (104° F.) it melts to a dark-green liquid, which congeals again at 24° C. (73.2° F.). Allen gives the saponification factor of laurel oil as 198.9, and according to v. Hübl it is capable of absorbing 49 per cent. of iodine.

Constituents.—Laurel oil consists mainly of trilaurin, $C_3H_5(C_{12}H_{23}O_2)_3$, but contains also trimyristin, $C_3H_5(C_{14}H_{27}O_2)_3$, some resin, chlorophyll, and a volatile oil, which latter can be removed by means of alcohol. It is sometimes adulterated with tallow and lard.

The P. G. requires that if laurel oil be warmed with twice its weight of alcohol, the resulting solution, having been decanted when cold, shall not assume a brown color upon addition of ammonia-water.

Action and Uses.—Bayberry oil is employed locally in the treatment of muscular rheumatism, sprains, contusions, and other local pains. It is rarely if ever employed internally.

OLEUM LAVANDULÆ FLORUM, *U. S., Br., P. G.*—Oil of Lavender Flowers.

Oleum Lavandulæ.—Essence de Lavande, Fr.; *Lavendelöl*, G.

A volatile oil distilled from the fresh flowering tops of *Lavandula officinalis* Chaix. (Fam. *Labiatæ*).

Although derived from the same species, and presumably from the same part of the plant, there are two oils in the market that differ so greatly in price and to such an extent in composition and properties that it is unsatisfactory to describe them under the same heading.

The *French* oil is obtained from the wild plant with the aid of itinerant stills, the distillers moving higher up on the mountains as the season advances. The collection begins with the flowering season in July, and the oil then obtained is regarded as inferior to that distilled toward the end of September at an altitude of 1500 M. It would seem that occasionally at least leaves are used as well as flowers. Most of the commercial oil is French oil.

The *English* oil is obtained exclusively from cultivated plants. The flowering tops alone are reported as being used. Only a small amount of oil is produced, and this, therefore, commands a much higher price than the ordinary commercial or French oil. Englishmen and those who prefer the English oil regard this as sufficient evidence of the superiority of the English oil, whereas Frenchmen do not concede this, and look upon the two oils as distinct products, referring to the differences in composition. Commercially the *English* oil is frequently designated as *oil of garden lavender.*

Properties.—Lavender flower oil is nearly colorless or slightly yellow, with the odor of the flowers. Rectification, which renders it colorless, impairs its odoriferous properties. It is said to improve as to odor when kept in a cool dark place for several years, but after that time deteriorates. The specific gravity according to the P. G. is 0.885–0.895; according to the U. S. P., it is 0.880–0.892 at 25° C. (77° F.); and according to the Br. P., 0.885–0.900. With 3 or more parts of 70 per cent. alcohol it forms a clear solution. Both oils are lævogyrate, not exceeding 10°.

Composition.—*French* oil has been found to contain linalool and geraniol, partly free, partly as ester, principally as acetate, but in small part also as propionate, butyrate, and valerianate. Calculated as linaloyl acetate, the ester content varies from 30 to 40 per cent. French oil has likewise been found to contain small amounts of pinene, although this hydrocarbon could not be isolated from an oil distilled from dry flowers. Cineol is also present in traces.

English oil has been shown to contain but 5–10 per cent. of linaloyl acetate and some free linalool; also limonene and sesquiterpene thus far not found in the French oil. The English oil differs furthermore in the large percentage of cineol present.

Adulterants and Tests.—The ordinary adulterants can be detected by the common methods (compare pages 1045 and 1046). Alcohol should be particularly tested for, since it is reported to be added in small amounts to prevent deterioration after a certain time. Spike lavender is said to be distilled occasionally with true lavender. Spike oil, containing but a small amount of linaloyl acetate, reduces the ester content.

Although an uncompromisable difference of opinion exists as to the relative value of the linaloyl assay as applied indiscriminately to all oils, there appears to be none when this assay is taken as a means of testing French oil, even though it is well known that the esters are not the only constituents of importance. The French oils coming from the highest regions of the Alps are reported to contain 36 per cent. or more of ester. Some oils have an ester content as high as 45 per cent., but oils with an ester content below 30 per cent. may be regarded as suspicious and should be rejected.

For the saponification of volatile oils and the determination of their ester content, see page 1043.

Action and Uses.—Oil of lavender flowers is employed as a perfumer and as a flavoring agent for certain pharmaceuticals. It is rarely employed in medicine alone, but may be used both internally and externally for the relief of nervous headache. The internal dose is from 1 to 5 minims (0.05–0.3 Cc.).

OLEUM LIMONIS, *U. S., Br.*—Oil of Lemon.

Oleum citri, P. G., *Oleum limonum.—Essence de citron*, Fr.; *Citronenöl*, G.

A volatile oil obtained by expression from fresh lemon peel, yielding, when assayed by the process given below, not less than 4 per cent. of aldehyde, calculated as citral.—U. S.

Like orange and bergamot oils, oil of lemon is not obtained by steam distillation—with the exception of inferior oils—but by a mechanical rupture of the oil-cells and the collection of the oil thus liberated. One of three processes is commonly employed: (1) The *spugna* process, in which the rind is quartered and the oil from the ruptured cells is collected by a sponge; (2) the *scorzetta* process, in which the halves of the rind are not broken in the process, the oil being likewise collected with the aid of a sponge; (3) the *machina* process, in which a complicated machine is substituted for the manual labor of expression and collection, especially for bergamot oil. A fourth process, involving the *ecuelle à piquer*, is but little used. Most of the oil of commerce is produced in Sicily and the southern part of Calabria.

Properties.—The pale-yellow color of the expressed oil distinguishes it from the colorless distilled oil, which is inferior and not official. The oil should be fragrant like the peel of the lemon and not possess a terebinthinate odor. The latter odor may either indicate addition of turpentine oil or deterioration of an originally good oil due either to age or improper keeping. Such an oil should not be rectified by distillation, this process being excluded by the pharmacopœias because detrimental to a good oil. The somewhat bitterish taste of the expressed oil is stated to distinguish it from a distilled product, the expressed oil containing non-volatile constituents.

The specific gravity requirements of the Br. P. are 0.857–0.860, those of the P. G. 0.858–0.861; those of the U. S. P. of 1890 were 0.858–0.859 at 15° C. (59° F.), but have been extended to 0.851 to 0.855 at 25° C. (77° F.). According to the Br. P., the angle of rotation should be not less than 59°; according to the U. S. P., not less than 60°, while the P. G. has no such requirement. The angle rarely exceeds 64°. The angle of rotation of the first 10 per cent. of oil obtained by fractional distillation should not differ more than 2° from that of the original oil (U. S.). The solubility of the oil in alcohol is often of questionable utility as a test.

Composition.—While a decade ago oil of lemon was regarded as a typical hydrocarbon oil, consisting to the extent of 90 per cent. of dextrogyrate limonene, it is to-day frequently valued according to its citral content, of which it should contain at least 4 per cent. (?), according to the U. S. P., the other pharmacopœias not having as yet adopted such a standard. Besides limonene and citral, the oil has been found to contain cymene (?), phellandrene, pinene, citronellal, geranyl acetate, a sesquiterpene, octyl aldehyde, nonyl aldehyde, methyl heptenone, terpineol. However, a mixture, in proper proportions, of these numerous constituents will scarcely be acceptable to a connoisseur as a substitute for the natural oil.

Tests and Assay.—While the presence of the proper amount of citral is by no means a guarantee of a pure oil, the citral assay supplements the physical and other tests commonly employed. The crude adulterations with turpentine oil, readily detected with the polariscope, are no longer so common as formerly, but "citrene," the by-product in the manufacture of concentrated and terpeneless lemon oil, is the more dangerous adulterant of to-day. The addition of citral from other sources cannot be detected by the assay unless it has been added in excess.

Assay of Oil of Lemon for Citral.—Introduce into a counterpoised 150 Cc. flask, by means of a pipette, about 5 Cc. of oil of lemon, and note the exact weight, add 5 Cc. of distilled water and a few drops of phenolphthalein test-solution, and then neutralize the solution exactly by the cautious addition of tenth-normal sodium hydroxide solution. Add 25 Cc. of a neutral solution of sodium sulphite (1 in 5), and immerse the flask in a water-bath containing boiling water. From a burette add, as needed, just sufficient half-normal hydrochloric acid to maintain the neutrality of the mixture, keeping the flask continuously heated and

frequently agitated, and adding a drop or two of phenolphthalein test-solution. When a permanent condition of neutrality is reached, note the number of cubic centimeters of half-normal hydrochloric acid consumed. Carry out a blank test, identical with the foregoing, except that the oil of lemon is omitted, and note the amount of half-normal hydrochloric acid consumed. Subtract the number of cubic centimeters required in the blank test from the number required in the original test; each Cc. of this difference corresponds to 0.03802 Gm. of citral. To find the percentage, multiply the above difference by 0.03802, and this product by 100, and divide by the weight of the oil of lemon taken.—U. S.

Besides the official gravimetric method, the following volumetric method may also be employed: Transfer 5 Cc. of the oil with a pipette to a flask with a long narrow graduated neck, add 25 Cc. of a 30 per cent. sodium acid sulphite solution and place the flask in a water-bath at a temperature of 60° C. (140° F.) for 30 minutes, shaking the flask from time to time. After allowing the flask and contents to cool completely, dilute gradually with distilled water, shaking well after each addition, until the flask is filled. The decrease in volume of the oil indicates the quantity of citral originally present, from which the volume percentage can be quickly calculated.

Action and Uses.—Oil of lemon possesses stimulant and aromatic properties, but it is rarely employed in medicine. It is used principally to impart an agreeable odor to medicines.

OLEUM LINI, *U. S.*, *Br.*, *P. G.*—Linseed Oil.

Flaxseed oil, E.; *Huile de lin*, Fr.; *Leinöl*, *Leinsamenöl*, G.

The fixed oil expressed from linseed (Fam. *Linaceæ*). Linseed oil which has been boiled should not be used nor dispensed.—U. S.

Preparation.—This oil is made on the large scale by thoroughly drying the seed with the aid of heat, crushing and forcibly expressing it. The yield by cold pressure is 16 to 20 per cent., by hot pressure 25 to 28 per cent. It is largely manufactured in the United States.

Properties.—Linseed oil, when expressed in the cold, is limpid, neutral to test-paper, of a yellowish color, and has a peculiar, rather unpleasant odor, and a bland taste. For use in the arts, the oil is largely obtained by hot pressure, and is then somewhat thicker, brownish in color, and has more odor and a slightly acrid taste. The U. S. P. gives its specific gravity as 0.930–0.940 at 15° C. (59° F.) or 0.925–0.935 at 25° C. (77° F.). Linseed oil imparts its yellow color to alcohol when shaken with it, and dissolves in 40 parts of cold and 5 parts of boiling alcohol (10 parts of 90 per cent. alcohol, Br.), in 10 parts of absolute alcohol, and in all proportions in chloroform, ether, carbon disulphide, benzin, and oil of turpentine. It does not congeal above —20° C. (—4° F.). When boiled with alkalies, it yields a very soft soap. When exposed to air, linseed oil gradually thickens, assumes a disagreeable odor, and finally solidifies. The solidified varnish-like mass contains linoxyn, formed as the result of oxidation, the increase in weight amounting to 12 to 14 per cent. Heated to 130° C. (266° F.), the oil begins to boil, the temperature gradually rising, and when it has lost about 5 or 8 per cent. of its weight it constitutes boiled linseed oil (see page 1082).

Composition.—Linseed oil consists of 10 to 15 per cent. of a mixture of palmitin, myristin, and stearin, and 85–90 per cent. of the liquid glycerides of oleic acid ($C_{18}H_{34}O_2$), linoleic acid ($C_{18}H_{32}O_2$), linolenic acid ($C_{18}H_{30}O_2$), and isolinoleic acid ($C_{18}H_{32}O_2$), which acids occur in about the respective ratios of 5, 15, 15, and 65 (Hazura and Grüssner, *Jour. Chem. Soc.*, 1888). According to S. Fokin (*Jour. Chem. Soc.*, 1902), the chief constituent of linseed oil is linolic acid, with 22–25 per cent. of linolenic acid and about 5 per cent. of solid fatty acids. Linseed oil contains about 1 per cent. of non-saponifiable matter.

Tests.—If 2 Cc. of linseed oil be shaken with 1 Cc. each of fuming nitric acid and water it should not solidify (not even partially) after standing for one or two days. If spread in a thin layer on a glass plate and allowed to stand in a warm place, linseed oil is gradually converted into a hard transparent resin (absence of non-drying oils). It should not more than slightly redden blue litmus-paper previously moistened with alcohol (limit of acid). The oil should be completely saponifiable with alcoholic potassium hydroxide solution and the resulting soap should be completely soluble in water without leaving an oily residue (absence of mineral oils and rosin oil). If 2 Cc. of the oil be warmed and shaken in a test-tube with an equal volume of acetic anhydride, and to the mixture, after cooling, is added 1 drop of sulphuric acid, a greenish color is produced

(a violet color under these circumstances indicating the presence of rosin and rosin oils). Linseed oil saponified by alcoholic potassium hydroxide test-solution should show a saponification value of from 187–195. If 0.15 Gm. of unboiled linseed oil be dissolved in 10 Cc. of chloroform and placed in a 250 Cc. flask with 25 Cc. of a mixture of equal parts of alcoholic iodine test-solution and alcoholic mercuric chloride test-solution, and after standing for 16 hours protected from the light, 20 Cc. of potassium iodide test-solution be added and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate solution an iodine value of not less than 170 should be obtained.—U. S. The P. G. requires an iodine value of only 150, which appears much too low, since pure linseed oil has frequently been found to absorb from $1\frac{3}{4}$ to $1\frac{9}{10}$ times its weight of iodine. Exposure to air and light causes a gradual lowering of the iodine value of linseed oil; the same change has been observed in old oil.

The world's crop of flaxseed for the year 1900 amounted to 64,466,500 bushels, of which the U. S. produced 31.02 per cent., capable of producing 50,000,000 gallons of oil and about 380,000 tons of oil-cake. The oil is mostly consumed in the home market, only 99,919 gallons having been exported from the U. S. for the fiscal year ending June 30, 1901. The amount of linseed oil-cake exported for the same period amounted to 227,527.4 tons, valued at $5,471,930.

Boiled Linseed Oil.—Although for medicinal purposes raw linseed oil should always be used, there is a large demand for boiled linseed oil for use in the arts, particularly by painters, since the latter variety dries far more rapidly. It is prepared by heating linseed oil to a temperature of 130° C. (266° F.), while a current of air is passed through it, or by incorporating during the heating process such substances as litharge, red lead, manganese dioxide, lead acetate, or manganous borate, whereby the drying properties of the oil are very materially increased. Boiled linseed oil is much darker and thicker than the raw oil, and has a specific gravity of 0.939–0.950.

Action and Uses.—Linseed oil is rarely employed in medicine because of its disagreeable taste. It possesses laxative properties and is said to be efficacious in the treatment of piles. Locally applied in the form of linimentum calcis it is an excellent remedy for the relief of burns and scalds. The internal dose is from 1 to 2 fluidounces (30–60 Cc.).

Other Drying Oils.—The following oils may be conveniently considered here, although they differ materially in their properties. Some of them have been used as adulterants for linseed oil:

Candle-nut Oil.—*Kekune oil, Bankul oil,* E.; *Huile de noix de chandelle,* Fr.; *Bankulnussöl, Kandelnussöl,* G.—The candle-nut-tree, *Aleurites triloba* Forst., s. *A. moluccana* Willd., is extensively cultivated in the islands of the Pacific and Indian Oceans and in India. The whitish kernels have a bland nutty flavor and yield about 60 per cent. of nearly colorless oil, which dries rapidly and is colored dark orange red by nitric acid and yellow to brown by sulphuric acid. It consists of an olein resembling linolein, besides myristin, palmitin, and stearin.

Corn Oil.—*Indian corn oil, Maize oil,* E.; *Huile de mais, Huile de papetons,* Fr.; *Maisöl,* G.—This oil is expressed from the seed of *Zea Mays* L.—Fam. *Gramineæ,* and occurs as a golden-yellow fluid of 0.9213–0.9215 specific gravity. When obtained by extraction the oil has a brownish color. The peculiar odor and taste are said to be due to the presence of a volatile oil (Vulté and Gibson). It is readily soluble in acetone, but with difficulty in alcohol and glacial acetic acid. It contains the glycerides of palmitic, stearic, arachic, oleic, and linolenic acids, and if exposed in thin layers on a glass-plate at 50° C. (122° F.) it dries perfectly in 18 hours. If a drop of sulphuric acid be added to a solution of corn oil in carbon disulphide, a violet coloration occurs after 24 hours, due to the presence of phytosterin (Vulté and Gibson). Its saponification value lies between 191 and 193, and its iodine value between 113 and 120. Subjected to the elaidin test it produces a mass of lard-like consistence.

Grape-seed Oil.—*Huile de raisin,* Fr.; *Traubenkernöl,* G.—The seeds of the different varieties of *Vitis vinifera* L.—Fam. *Vitaceæ,* yield from 10 to 20 per cent. of fixed oil, which is light-yellow or brownish, inodorous, faintly bitter, and congeals near —16° C. (3.2° F.) and has a specific gravity at 15° C. (59° F.) of 0.920. It dries very slowly, and consists, besides palmitin and stearin, chiefly of the glyceride of *erucic acid,* $C_{22}H_{42}O_2$; this acid melts at 34° C. (93.2° F.), and yields acetic and arachic acids on being fused with potassium hydroxide. The oil dissolves readily in glacial acetic acid at 70° C. (158° F.); the solution becoming turbid on cooling to 66.5° C. (151.5° F.). The iodine value of the oil is 94–96.2, and the saponification value 178–179.

Hempseed Oil.—*Huile de chanvre, Huile de chenevis*, Fr.; *Hanföl*, G.—When freshly expressed from the seed of *Cannabis sativa* L.—Fam. *Urticaceæ*, hempseed oil has a pale-green to greenish-yellow color, which slowly changes to brownish-yellow. It has a mild taste and peculiar odor, and dries very readily. The oil is soluble in 30 parts of cold alcohol, and if dissolved in 12 parts of boiling alcohol the solution, upon cooling, separates stearin. Besides the latter, it contains palmitin and linolein. Hempseed oil boiled with a solution of caustic soda of 1.34 specific gravity yields a brownish-yellow hard soap, whereas linseed oil, similarly treated, yields a soft yellow soap. If hempseed oil be mixed with one-fifth of its volume of a mixture of equal parts of fuming nitric acid, concentrated sulphuric acid, and water, a green color is produced, rapidly changing to black, and finally, after 24 hours, becoming reddish brown. The saponification value of hempseed oil lies between 193 and 195, and its iodine value varies from 140.5–166.

Madia Oil.—*Huile de Madia*, Fr.; *Madiaöl*, G.—This oil is obtained from *Madia sativa*, Molina—Fam. *Compositæ*, an annual herb, native of Chile and cultivated in Europe, Africa, and Asia. The brownish-gray, quadrangular, 4-ribbed akenes, which are destitute of pappus, yield about 40 per cent. of fixed oil. This is yellow, bland, of a peculiar odor, and has the specific gravity 0.928 at 15° C. (59° F.), and congeals near —20° C. (—4° F.). On exposure to air it becomes rancid and slowly acquires a soft-solid consistence. By nitric acid it is colored brown red, by sulphuric acid, greenish and brown. Besides palmitin and stearin, it contains an olein, which seems to differ from that of other oils. Its iodine value is 117.5–119.5; its saponification value 192.8 (de Negris and Fabris).

Niger-seed Oil.—*Huile de Niger*, Fr.; *Nigeröl*, G.—Niger-seed oil, *Guizotia oleifera* DC., s. *Verbesina sativa* Roxb.—Fam. *Compositæ*, is indigenous to and cultivated in India and Eastern Africa. The subcylindrical, black, and glossy akenes yield about 40 per cent. of a thin yellow oil, having a nutty flavor and congealing below —10° C. (14° F.). The specific gravity of the oil at 15.5° C. (60° F.) is 0.9270. It is colored orange yellow by nitric acid, and gray green and brown by sulphuric acid, dries to a soft varnish, and consists of myristin, palmitin, and apparently two oleins, one of which is closely related to linolein. The iodine value of the oil is 133–133.5; the saponification value 189–192.

Pumpkinseed Oil.—*Pumpkin oil*, E.; *Huile de semences de calabasse d'Europe*, Fr.; *Kürbiskernöl*, G.—*The seed of Cucurbita Pepo* L.—Fam. *Cucurbitaceæ*, yield by cold expression about 20 per cent. of reddish-colored oil of 0.920–0.925 specific gravity. By extraction with ether the yield may be increased to 30 or 35 per cent. The oil, when fresh has a pleasant odor and taste, and forms a clear solution with ether, chloroform, and carbon disulphide, and 20 parts of absolute alcohol. When exposed to the air, it slowly dries, forming a yellowish transparent film. Its saponification value is given as 188.7 by Schattenfroh, and as 192.5–195.2 by Graham. Pumpkinseed oil congeals at —16° C. (3.2° F.), and is capable of absorbing from 113.4 to 130.7 per cent. of iodine.

Sunflower Oil.—*Huile de tournesol*, Fr.; *Sonnenblumenöl*, G.—The kernels of sunflower seed, derived from *Helianthus annuus* L.—Fam. *Compositæ*, contain about 40 per cent. of a limpid, pale-yellow oil, which upon exposure to air dries slowly. It has the specific gravity 0.924–0.926 (Allen), and possesses a mild taste and rather pleasant odor. It consists of linolein, olein, and palmitin, and congeals between —16° and —18° C. (3.2° and —4° F.). Sunflower oil when shaken with nitric acid of 1.37 specific gravity does not change color, but when mixed with concentrated sulphuric acid a golden-yellow color within a zone of grayish blue is produced. When boiled with caustic alkali solution it yields a soft soap, the saponification value being 193–194. Its iodine value varies from 123–133.

Walnut Oil.—*Nut oil*, E.; *Huile de noix*, Fr.; *Walnussöl*, *Nussöl*, G.—This oil, obtained by expression from the kernels of *Juglans regia* L.—Fam. *Juglandaceæ*, is particularly prized by artists as a drying oil, since the varnish produced by it does not crack like that from linseed oil. The kernels contain from 30 to 40 per cent. of a thin almost colorless or pale greenish-yellow oil of 0.925–0.926 (Allen) specific gravity, and having a pleasant odor and taste. When expressed by aid of heat, the oil is more deeply colored and has a sharp taste. It is soluble in about 100 parts of cold or 60 parts of hot alcohol. Walnut oil is composed of the glycerides of linolic, linolenic, oleic, myristic, and lauric acids, and thickens when cooled to —15° C. (5° F.), but does not congeal until the temperature falls to —27.5° C. (—17.5° F.) (Benedikt-Ulzer, *Analyse d. Fette*, 1903). Its saponification value lies between 188 and 196, and its iodine value is about 142–145. Pure walnut oil is difficult to obtain, according to Kebler, and the bulk of oil sold in this market is said to be a mixture of varying composition. The oil from hickory nuts resembles walnut oil very much and is sold as American Nut Oil. Kebler has found the oil from black walnuts, *Juglans nigra*, to be excellent as a drying oil. The kernels contain about 60 per cent. of oil, of which 25 per cent. can easily be obtained by cold expression. It is limpid, straw yellow, of pleasant odor and taste, has a specific gravity of 0.9215 at 15° C. (59° F.), and becomes turbid when cooled to —12° C. (—10.4° F.). Its saponification value is 190.1–191.5 and its iodine value 141.4–142.7.

Wood Oil.—*Chinese wood oil, Japanese wood oil.*—Under this name the oil of the nut of

the tung tree, *Aleurites cordata* (*Elæococca cordata*, *E. vernicia*, *Dryandra cordata*, *D. vernicia*), is largely used in China and Japan, and thence exported. In China the oil is known as *Pai-Yu*, *Hsin-Yu*, and *Hung-Yu*, and commercially two varieties are sold as Canton oil and Hankow oil, of which the former is considered the better and commands a higher price. The kernels of the nut contain about 58 per cent. of a pale-yellow oil, which becomes darker by exposure, and has a specific gravity of 0.938–0.943 at 15° C. (59° F.). The oil is almost insoluble in cold absolute alcohol, but is soluble in ether, benzin, and chloroform, and when expressed cold from sound kernels the fresh oil has little or no taste, but gradually a characteristic disagreeable odor and taste are developed, especially upon exposure to air. Wood oil remains liquid at —13° C. (8.6° F.), but congeals at —18° C. (—4° F.), and is the strongest drying oil known. Its saponification value is given as 191–196, and its iodine value as 150–165. The oil is known to be poisonous, and hence not suitable for use in pharmacy and medicine, but is very extensively used in the manufacture of varnishes, oil-cloths, etc.

OLEUM MENTHÆ PIPERITÆ, *U. S.*, *Br.*, *P. G.*—Oil of Peppermint.

Essence de menthe poivrée, Fr.; *Pfefferminzöl*, G.

A volatile oil distilled from the fresh or partly dried leaves and flowering tops of peppermint, rectified by steam distillation and yielding, when assayed by the process given below, not less than 8 per cent. of ester, calculated as menthyl acetate, and not less than 50 per cent. of total menthol (free and as ester).—U. S.

The distillation of peppermint oil has developed into an important agricultural industry in Michigan. Considerable oil is also distilled in western New York. While oil is exported, some English and possibly German oil of the finer grades is imported. Japanese oil is largely imported at times, principally for the manufacture of menthol.

Properties.—While the crude oil is yellowish or greenish yellow, the rectified oil is colorless, having the peculiar odor of peppermint. The U. S. P. allows the specific gravity to range between 0.894 and 0.914 at 25° C. (77° F.), and the Br. P. from 0.900 to 0.920 at 15.5° C. (60° F.); whereas the P. G. restricts it to the limits 0.90–0.91. It is soluble in an equal volume of alcohol, and in 4 volumes of 70 per cent. alcohol with at most a trifling opalescence. The angle of rotation may vary from —25° to —33°.

Composition.—American peppermint oil, which has been most carefully examined, has been found to contain amyl alcohol, acetaldehyde, isovaleric aldehyde, acetic acid, isovaleric acid, pinene, phellandrene, limonene, cineol, menthone, menthol, menthyl acetate, menthyl isovalerate, menthyl ester of an acid $C_8H_{12}O_2$, a lactone $C_{10}H_{16}O_2$, cadinene, and dimethyl sulphide. In the English oil pinene (?), phellandrene, and a sesquiterpene (in Japanese oil only a sesquiterpene) have been identified, besides menthone and menthol and esters of the latter. Menthol and its esters are the principal constituents of the oil. The fatty alcohols, aldehydes, and acids, also the dimethyl sulphide, though present only in small quantity, are regarded as objectionable for flavoring purposes, and should therefore be removed by the process of rectification with steam.

Adulterations and Tests.—While occasionally crude adulteration is still met with, the manufacture of menthol on a large scale has thrown upon the market considerable quantities of a more dangerous adulterant than turpentine oil, viz., dementholized oil. Although the lower specific gravity will indicate any considerable amount of such an addition, the menthol assay gives by far the most satisfactory results. While the menthol manufacturer prefers an oil which contains the largest amount of free menthol, peppermint oil rich in menthyl esters is regarded superior for flavoring purposes. Peppermint oil is, therefore, assayed for free menthol and menthol present as ester, the sum of the two yielding the total menthol. The amount of ester is ascertained by saponification, the amount of free menthol by acetylization and subsequent saponification. The older method of freezing out the menthol is unsatisfactory not only because inexact but also because some of the best oils rich in menthyl ester are apt to retain the menthol in solution even at a low temperature, and thus fall short according to this test. "If from 25 Cc. of oil about 1 Cc. be distilled, and the distillate poured on an aqueous solution of mercuric chloride, a white film should not form at the zone of contact after a short time (absence of dimethyl sulphide found in non-rectified oils)."—U. S.

Assay of Oil of Peppermint.—Introduce into a tared flask 10 Cc. of oil of peppermint, and note the exact weight; add 25 Cc. of half-normal alcoholic potassium hydroxide solution,

connect with a reflux condenser, and boil the mixture during 1 hour. After cooling, titrate the residual alkali with half-normal sulphuric acid solution, using phenolphthalein test-solution as indicator. Subtract the number of cubic centimeters of half-normal sulphuric acid solution required from the 25 Cc. of half-normal alcoholic potassium hydroxide solution taken multiply the difference by 9.834, and divide the product by the weight of the oil of peppermint taken to find the percentage of menthyl acetate. Wash the residual oil repeatedly with water, transfer it to a flask provided with a ground-glass tube-condenser (acetylization flask), add 10 Cc. of acetic acid anhydride and about 1 Gm. of anhydrous sodium acetate, and boil gently during 1 hour. Allow it to cool, wash the acetylized oil with distilled water, and afterward with sodium hydroxide test-solution, until the mixture is slightly alkaline to phenolphthalein test-solution, and then dry it with the aid of fused calcium chloride, and filter. Transfer to a tared 100 Cc. flask 5 Cc. of the dry acetylized oil, note the exact weight, add 50 Cc. of half-normal alcoholic potassium hydroxide solution, connect with a reflux condenser, and boil the mixture during 1 hour. After cooling, titrate the residual alkali with half-normal sulphuric acid solution, using phenolphthalein test-solution as indicator. Subtract the number of cubic centimeters of half-normal sulphuric acid solution required from the 50 Cc. of half-normal alcoholic potassium hydroxide solution taken, multiply the difference by 7.749, and divide the product by the weight of the dry acetylized oil taken, less the above difference multiplied by 0.021 ; the quotient will represent the percentage of menthol in the oil of peppermint.

Note.—The difference referred to above represents the number of cubic centimeters of half-normal alcoholic potassium hydroxide solution consumed by the acetylized oil.—U. S.

The amount of menthone is determined in the following manner : After the menthol content has been determined with a part of the saponified oil, another part is diluted with twice its volume of alcohol and boiled for some time with metallic sodium. Thereby the menthone is reduced to menthol, which may be assayed as described above.

Action and Uses.—Oil of peppermint possesses stimulant, carminative, and anodyne properties. It is employed internally in the treatment of flatulent colic, nausea, and vomiting, and as an adjuvant to purgative remedies. It is also efficacious when locally applied in the treatment of superficial neuralgias and muscular rheumatism. A solution containing from 5 to 10 per cent. in oil or alcohol may be applied for the relief of pruritis. The internal dose is from 2 to 5 minims (0.10–0.30 Cc.).

OLEUM MENTHÆ VIRIDIS, *U. S., Br.*—Oil of Spearmint.

Essence de menthe verte, Fr. ; *Krauseminzöl,* G.

Whereas American spearmint oil is the volatile oil distilled from the fresh or partly dried leaves and flowering tops of *Mentha spicata* L. (Fam. *Labiatæ*), which is regarded as a probable cultural variety of *M. silvestris* L., the German spearmint oil (Krauseminzöl, Essence de menthe crépue) is distilled in small amounts from *M. crispa* L., which is regarded as a cultural variety of *M. aquatica* L. The botanical source of the Russian oil is not known ; the Portuguese oil is stated to be derived from *M. rotundifolia glabra.* Of these oils, only the oil from *M. viridis* comes into consideration in the United States and in England.

Properties.—Crude spearmint oil is a yellowish or greenish-yellow liquid, whereas the rectified oil is colorless. Both possess the odor peculiar to the herb. Its specific gravity may vary between 0.914 and 0.934 at 25° C. (77° F.), according to the U. S. P. The angle of rotation of the commercial oils varies between —36° and —48°. It is soluble in an equal volume of 80 per cent. alcohol, but may become turbid on the addition of more alcohol.

Composition.—American spearmint oil consists principally of about equal portions of *l*-carvone and *l*-limonene (see Oil of Caraway) and possibly a small amount of an unidentified alcohol $C_{10}H_{17}OH$. To what substances it owes its peculiar odor is not known.

Tests.—Inasmuch as spearmint oil can be adulterated with cheaper oils so as to correspond with pure oil as to specific gravity and rotatory power, the carvone assay is one of the best tests of its purity (see Oil of Caraway). While the lessened solubility in alcohol may indicate such adulteration, the assay will reveal the extent of the adulteration as well.

Action and Uses.—The employment of this oil is practically the same as that of Oleum Menthæ Piperitæ (which see). The dose is from 2 to 5 minims (0.10–0.30 Cc.).

OLEUM MORRHUÆ, *U. S., Br.*—Codliver Oil.

Oleum jecoris aselli, P. G.; *Oleum hepatis morrhuæ.—Cod oil*, E.; *Huile de morue, Huile de foie de morue*, Fr. Cod.; *Lebertran, Dorschlebertran, Stockfischlebertran, Kabliaulebertran*, G.; *Aceite de higado de bacalao*, Sp.

A fixed oil obtained from the fresh livers of *Gadus Morrhua* L., and of other species of *Gadus* (Class *Pisces;* Ord. *Teleostia;* Fam. *Gadidæ*).

The oil extracted from the fresh liver of the cod, *Gadus Morrhua* L. (Brandt and Ratzeburg, *Med. Zoöl.*, vol. ii., tab. ix., Fig. 3), by the application of a temperature not exceeding 82.2° C. (180° F.), and from which solid fat has been separated by filtration at about —5° C. (23° F.).—Br.

Origin.—The *common cod*, formerly called *Asellus major*, inhabits the Northern Atlantic, and is frequently met with on the North American coast on and near the Banks of Newfoundland, where it seems the *hake, G. Merluccius* L., s. *Merluccius communis* Cuvier, *pollack, G.* (*Merlangus* Cuvier) *pollachius* L., and *haddock, G. æglifinus* L., are likewise used to some extent for the same purpose. On the Norwegian coast, according to de Jongh (1843), codliver oil is mainly produced from the *dorse, G. Callarius* L., but also from the *pollack*, the *coal-fish, G.* (*Merlangus* Cuvier) *carbonarius* L., the *whiting, Merlangus vulgaris* Cuvier, s. *G. Merlangus* L., and the *ling, Gadus* (*Lota* Cuvier) *Molva* L.

The Norwegian cod fisheries are chiefly located on the Lofoten Islands, where annually in the neighborhood of 400,000 gallons of oil are produced. This oil is considered by many to be the best in the world, although oil of equally fine quality can be produced on this continent, mainly on the coast of Newfoundland. New England fishermen go in large numbers to the Banks of Newfoundland, where they are allowed to secure their supply of codfish outside the 3 mile limit from the coast. Considerable literature has been published on the subject of codliver oil, beginning with the researches of de Jongh in 1843 and leading up to very recent times.[1]

Preparation.—On the coast of Norway the carefully cleaned livers are placed in baskets or barrels exposed in a sunny place, where the oil slowly exudes, and is removed and filtered; or the livers are slowly heated in a steam- or water-bath, or sometimes boiled with water, the oil being skimmed from the surface. A patented process is in use in Norway for rendering the oil from codlivers in an atmosphere of carbon dioxide, whereby it is claimed all danger of oxidation is prevented and the oil obtained in its natural pure state. On the coast of North America codliver oil is now generally very carefully prepared. The introduction of ice as a means of preserving has developed the business of transporting codfish fresh to the inland cities during the catching season, from December to March, and likewise that of the proper preparation of codliver oil from fresh livers on shore by means of gradually applied steam-heat, whereby the oil is separated from the tissues, the watery portion subsiding; the oil is placed in butts in the cooling-room until it freezes solid, when it is put into canvas bags and expressed; the hard, yellowish residue, consisting of fish-stearin and liver débris, is sold to soapmakers, while the clear oil is bottled or put into dry barrels.

The pale oil thus obtained is known as *shore oil.* A second quality varying in color from brownish yellow to pale brown, is known among fishermen as *straits oil.* It is procured by throwing the livers, when taken from the fish and cleaned, into barrels or tanks where gradual decomposition takes place, and the first oil rising to the surface is removed. After putrefaction has advanced, a dark-brown oil of inferior grade, and known as *banks oil*, is collected, which is unfit for medicinal purposes, having a marked acid reaction, disagreeable odor, and an acrid, bitter taste.

The yield of codliver oil varies much from year to year. In 1898 the Newfoundland catch of 171 ships amounted to 28,691.2 tons of fish, producing about 3835 barrels of medicinal oil. The mean annual yield for 1893 to 1900 for the Lofoten Islands, from which the best Norwegian oil is obtained, averaged 13,168 barrels of oil (E. Lepinos, *J. S. C. I.*, 1901).

Properties.—The purest codliver oil is of a pale-yellow color, never quite colorless unless artificially bleached; it is limpid, has a slight fishy but not rancid odor, a bland slightly fishy taste, and a faint acid reaction; but if prepared at a high temperature, or

[1] Those interested are referred to the excellent monograph by F. Peckel Möller, entitled Codliver Oil and Chemistry, London, 1895, and also articles in the Proc. Amer. Pharm. Assoc. for 1875, 1876, 1895, 1903, and 1904, the Western Druggist for 1897, and Merck's Report for 1899.

if the livers are allowed to putrefy more or less, it has a more decided reaction and a pale or darker reddish-brown color, the darkest varieties being transparent only in thin layers, and having a repulsive fishy odor and a bitterish, acrid taste. The acridity and fishy smell are less marked in the light-brown oil, and still less in the yellow or white oil, which is nearly bland. The specific gravity of codliver oil is given as 0.920–0.930 (Br. 0.922–0.927 at 15° C. (59° F.) or 0.918–0.922 at 25° C. (77° F.) (U. S.), and 0.926–0.931 (P. G.). Cold alcohol dissolves not over 2.5 per cent. from the yellow, but about 6 per cent. from the dark-brown, codliver oil; boiling alcohol dissolves 1 or 2 per cent. more. It is scarcely soluble in alcohol, but readily soluble in ether, chloroform, or carbon disulphide; also in 2.5 parts of acetic ether (U. S.). At temperatures below 0° C. (32° F.) a granular crystalline deposit is separated from codliver oil, being in largest proportion from the dark-colored oil, and at 10° C. (4° F.) the oil congeals. On the addition of sulphuric acid to the oil, a violet color, gradually changing to brown red, is produced, due to the presence of biliary compounds; this color is even observed if a glass rod merely moistened with sulphuric acid is drawn through a thin layer of the oil. The violet color is also produced on shaking a solution of 1 drop of codliver oil in 20 drops of chloroform with 1 drop of sulphuric acid, but the color is very transient and becomes pale red and finally brownish yellow. In contact with nitrous acid the oil becomes thicker, but does not solidify. There is a difference in the refractive index between American and Norwegian oils, the former ranging from +42 to +44.5 and the latter from +44 to +48 (E. W. Dowzard).

Adulterations.—American codliver oil is said to be often adulterated with seal oil and menhaden and other fish oils, whereas the Norwegian oil is chiefly admixed with oils from the livers of haddock, ling, and ray or skate, and at times with seal and mineral oils. Lard oil has also been met with as an adulterant.

Tests.—Codliver oil should be only very slightly acid to litmus-paper previously moistened with alcohol (limit of free fatty acids) (U. S., P. G.). Steam-pressed codliver oil contains from 0.3 to 1.5 per cent. of free fatty acids. No solid fat should separate on exposure of the oil to a temperature of 0° C. (32° F.) (Br., P. G.). 1 Gm. of the oil saponified with 20 Cc. of seminormal alcoholic potassium hydroxide solution by boiling under a reflux condenser for one-half hour, should require not less than 13 Cc. of seminormal hydrochloric acid for neutralization, using phenolphthalein as indicator (P. G.). From the dried soap after complete saponification of the oil, not more than 1.5 per cent. of unsaponifiable matter should be extractable by petroleum ether. The development of the violet color mentioned above under *Properties*, when sulphuric acid is added to codliver oil, is characteristic of all fish-oils, but will serve to detect the presence of seal oil. If 2 or 3 drops of fuming nitric acid be allowed to flow alongside of 10 or 15 drops of the oil, contained in a watch-glass, a red color will be produced at the point of contact. On stirring the mixture with a glass rod, this color becomes bright rose red, soon changing to lemon yellow (distinction from seal oil, which shows no change of color at first, and from other fish-oils, which become at first blue and afterward brown and yellow) (U. S.). The value of this latter test appears to be impaired by long keeping of the oil (*Pharm. Centralb.*, 1902, Beda). Although nitric acid is intended to detect the presence of seal oil, it has been shown by Gane (1903) that mixtures of equal volumes of codliver and seal oils readily pass this test. Seal oil is best distinguished by the very disagreeable odor of the soap obtained by boiling some of the oil with alcoholic potassium hydroxide solution, codliver oil and other fish oils yielding a soap of slight herring-like odor. When nitric acid is carefully poured into some of the oil contained in a test-tube, a precipitate of coagulated albumin should be formed at the surface of contact of the two liquids (Br.). This test is intended to show the absence of excessive amounts of free fatty acids, since the amount of albumin present is said to vary with the proportion of free fatty acids, but according to Gane the test is of little value. The U. S. P. requires that codliver oil, saponified by alcoholic potassium hydroxide test-solution, shall show a saponification value of 175 to 185. If 0.3 Gm. of codliver oil be dissolved in 10 Cc. of chloroform and placed in a 250 Cc. flask with 25 Cc. of a mixture of equal parts of alcoholic iodine test-solution and alcoholic mercuric chloride test-solution, and after standing for 4 hours protected from light, 20 Cc. of potassium iodide test-solution be added and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with decinormal sodium thiosulphate solution an iodine figure of not less than 140 nor more than 150 should be obtained (U. S.). This requirement, which is identical with

that of the P. G., is a useful aid in detecting adulterations other than fish-oils. Gane recommends (*Proc. Amer. Pharm. Assoc.*, 1903) that the time allowed for absorption be increased to 6 hours, and states that under these conditions genuine codliver oils will take up from 150 to 171 per cent. of iodine.

The reaction with nitric acid given above and the determination of the free fatty acid are among the most important tests in the examination of codliver oil. The latter may be carried out as suggested by Gane, as follows: Weigh carefully 25 to 50 Gm. of oil into a 200- or 250-Cc. flask and add 100 Cc. of alcohol which has been carefully neutralized. Shake well and raise to the boiling-point by means of a water-bath. Then add a few drops of phenolphthalein test-solution, and run in very cautiously half-normal sodium or potassium hydroxide solution from a burette until the liquid assumes a permanent pink tint. Note the number of Cc. of alkali solution used, and multiply this by 0.141, which will give the amount of free fatty acid present in the given weight of oil, calculated as oleic acid. Divide the product thus obtained by the weight of oil taken, and multiply the quotient by 100 to find the percentage of free acid.

Composition.—The composition of codliver oil is much affected by the method and care taken in its extraction and subsequent treatment. It is primarily a mixture of glycerides of stearic, palmitic, jecoleic, therapic, and a notable percentage of volatile fatty acids. Heyerdahl estimated the liquid fatty acids to contain 4 per cent. of *palmitic*, 20 per cent. of *jecoleic*, $C_{19}H_{36}O_2$, and 20 per cent. of *therapic*, $C_{17}H_{26}O_2$, acids. *Morrhuic* acid, $C_9H_{13}NO_3$, probably identical with de Jongh's *gaduine*, has been found in codliver oil, and *asellic* acid, $C_{17}H_{32}O_2$, was assumed as one of the constituents of the fatty acids by Fahrion (*J. S. Chem. Ind.*, 1893, p. 935).

Cholesterol, $C_{26}H_{42}.OH$, has been found as a constant constituent, the quantity varying from 0.46 to 1.32 per cent. The putrefactive changes which the livers undergo before the final extraction of the oil contribute to the development of some of the ptomainic bases found in some varieties of oil. The first oil exuding from the livers contains the least of the organic bases, while from the light-brown varieties of codliver oil *Gautier* and *Morgues* have obtained from 0.035 to 0.050 per cent. of organic bases. Among the bases thus far identified the most important are *trimethylamine*, *butylamine*, *iso-amylamine*, *hexylamine*, *dihydrotoluidine*, and the non-volatile bases *aselline*, $C_{25}H_{32}N_4$, and *morrhuine*, $C_{19}H_{27}N_3$. Of the elements, iron, manganese, magnesium, calcium, and sodium, sulphur, chlorine, bromine, iodine, and phosphorus have been found in more or less minute quantities in codliver oil. The phosphorus is mainly a constituent of a lecithin-like substance. Iodine, 0.00138 to 0.004 per cent., occurs as a usual constituent, but the medicinal qualities of codliver oil are attributable more to the peculiar composition and ready assimilability of the glycerides, rather than to the minute quantities of iodine and organic bases. The coloring-matter of the oil belongs to the class of lipochromes. The oil readily turns rancid, free fatty acids being liberated, on which account the pharmacopœias limit the quantity of free acid in medicinal oil.

The so-called fish-stearin present in codliver oil and obtained as a residue when the frozen oil is expressed, is not true tristearin, but consists, according to Heyerdahl, of a mixture of 20 per cent. of glycerides of saturated fatty acids and 80 per cent. of glycerides of unsaturated acids. The exact character of these unsaturated fatty acids has not been determined.

Action and Uses.—Codliver oil possesses certain peculiarities which separate it from other fatty substances which are sometimes employed in medicine. The bile salts which it contains materially aid in its emulsification and in its absorption from the intestine, and the fact that it contains iodine, bromine, phosphorus, and sulphur give it alterative powers which are of value, the patient being supplied not only with a readily assimilated form of fat, but at the same time with drugs which stimulate nutrition and enable the body to utilize the hydrocarbons after they are ingested. It is interesting to note that because of its bile salts, and perhaps of its chemical composition, codliver oil is six or eight times more diffusible through animal membranes than other oils, whether they be vegetable or animal. Taken in moderate quantity, varying from a teaspoonful to two tablespoonsfuls two or three times a day, it rarely produces disagreeable symptoms, but if the digestion is deranged, or if the doses are excessive, it may disorder the stomach and produce an oily diarrhœa. Codliver oil is used in medicine chiefly in cases of impaired nutrition connected with diathetic diseases such as chronic rheumatism, rickets, and anæmia, and in certain acute or subacute infections of which the type may be con-

sidered tuberculosis. In rheumatism it is particularly useful when the sheaths of the muscles and joints are chiefly affected, and when, associated with these conditions, there is marked anæmia and loss of flesh. In rickets it does good by improving nutrition, and often actually increases the appetite. In tubercular infection it finds its chief usefulness in those persons who do not suffer from a very active form of the disease, who possess a fairly good digestion, but who, nevertheless, lose flesh rapidly. It is important to remember that codliver oil cannot cure tubercular infection of any portion of the body, and that it does good only indirectly by improving nutrition and so maintaining, or improving, vital resistance. It is of greater importance that the patient shall eat good meals and have fresh air than that he shall take codliver oil, and if the oil disorders digestion, it is not only of no value, but harmful. In that form of chronic modified tubercular infection which at one time was designated scrofula or struma, codliver oil is often exceedingly useful. In some cases of chronic bronchitis which do not yield to ordinary remedies, the administration of codliver oil is followed by the most excellent results. Children can usually take larger doses of codliver oil in proportion to their size than adults, and often become very fond of it. As a rule its use is contra-indicated in all diseases if fever is present.

Codliver oil may be given in one of three ways: In soluble elastic capsules containing about 2½ grammes, in emulsion, and by placing it in a feeding cup with a long nozzle which will reach well back into the mouth, thereby conveying the oil past the lips and the tip of the tongue, which are the parts of the gustatory apparatus which are capable of noticing its taste. In this manner, too, its odor is not so well perceived by the olfactory nerves. Many other methods of administration have been resorted to, but are not particularly advantageous. One of these consists in placing it on top of some whisky in a glass and tossing it down the throat in such a way that only the whisky comes in contact with the mucous membrane of the mouth. The dose varies from a teaspoonful (4 Cc.) to 2 tablespoonsfuls (30 Cc.) 3 times a day for adults. In cases of marasmus occurring in children, whether due to syphilis or tuberculosis, codliver oil sometimes does great good, particularly in the former condition, when given by inunction. The infant should be anointed about the axillary spaces, abdomen, and the inside of the thighs with the oil, the nurse sitting with the child in front of a warm fire so that the circulation in the skin may be active, and then using massage to urge the oil through the epiderm. The disadvantages of this method is that it soils the child's clothes, and it is difficult to keep the patient clean. Small quantities of bile salts, over and above the quantity which it normally contains, mixed with the oil, may aid in the rapidity of its absorption when it is given by inunction.

Under the name of "Morrhuol," a proprietary preparation which is said to represent the active principles of codliver oil, is sometimes employed. It is useful in bronchitis, but does not possess the value of the oil itself.

Allied Oils.—OLEUM SQUALI.—*Shark oil*, E.; *Huile de requin, de selache*, Fr.; *Haileberthran*, G.—It is obtained from the liver of the shark, *Squalus Carcharias* L., and one or two allied species, and is the lightest of the fish-oils, its density at 15° C. (59° F.) being 0.870 to 0.880. It is light yellow, has an acrid taste, and remains limpid at —6° C. (21.2° F.).

OLEUM RAJÆ.—*Ray oil, Skate oil*, E.; *Huile de raie*, Fr.; *Rochenthran*, G.—It is obtained from the liver of *Raja, Batis*, L., and is employed in France and Belgium. The oil is pale or bright yellow, neutral, has the specific gravity 0.928 at 15° C. (59° F.), a slight fishy odor and taste, and dissolves in 2 parts of ether. It is stated to contain more iodine than codliver oil. Oil is also extracted from the liver of the American *stingray, Pastinaca hastata* De Kay.

Fish Oils.—These are in part obtained from different fishes, like the *Alosa Menhaden* Cuvier, which is caught on the New England coast and yields *menhaden oil*, principally employed in leather-dressing. But among fish oils are also included the so-called *train oils*, obtained from the fleshy parts of different cetacean mammals; the principal ones are:

OLEUM CETI.—*Sperm oil*, E.; *Huile de cachalot*, Fr.; *Pottfischthran*, G.—From *Physeter macrocephalus* L.; it is yellow or brown yellow, of specific gravity 0.920, and in the cold deposits spermaceti and stearin.

OLEUM BALÆNÆ.—*Whale oil*, E.; *Huile de baleine*, Fr.; *Walfischthran*, G.—From *Balœna mysticetus* L., and *B. australis* Desmoulins, the Greenland or right, and the cape or southern, whale. The oil has a peculiar fishy odor and unpleasant taste, a density of 0.926, and begins to deposit a sediment at about 10° C. (50° F.).

DUGONG OIL, from *Halicore Dugong* Cuvier, which inhabits the waters of Eastern Australia and the Indian Archipelago, has been used in place of codliver oil in Australia.

CANDLEFISH OIL.—*Eulachon Oil.*—A fixed oil obtained from the bodies of *Thaleichthys pacificus* (Richardson) Girard. This small fish is found in immense numbers in the waters of the northwestern coast of North America. It is a delicious food-fish, and the oil is extracted and used as a winter food by the Indians. The name "candle-fish" is derived from the ability to burn the dried body as a torch candle. The oil has been recommended as a substitute for codliver oil, being much more palatable, but it has not found favor. The dose is the same as that of codliver oil.

OLEUM MYRCIÆ.—Oil of Myrcia.

Oil of Bay, E.; *Essence de bay*, Fr.; *Bayöl*, G.

The volatile oil distilled from the leaves of *Pimenta acris* (Swz.) Wight (Fam. *Myrtaceæ*), which was official in the U. S. P. of 1890. The bay leaves of commerce are apparently not always derived from the same plant, but from different species yielding similar leaves. The oil is distilled partly from fresh material in the West Indies, partly from dried leaves in New York.

Properties.—Bay oil is a yellow liquid, which soon becomes brown on exposure to the air. Its odor suggests cloves and its taste is spicy. The specific gravity of the normal oil varies between 0.965 and 0.985, and, as a rule, is above 0.970. It is but slightly lævogyrate up to —2°. While the fresh oil yields a clear solution with 90 per cent. alcohol, upon standing the oil loses its solubility.

Composition.—The oil, which consists of from 60 to 65 per cent. of eugenol, also contains its isomer chavicol; further, methyl eugenol, methyl chavicol, citral, and the hydrocarbons phellandrene and myrcene, the latter of which is very unstable, and possibly causes the change of solubility of the oil in alcohol upon standing.

Adulterations and Tests.—Inasmuch as oil of bay apparently contains no pinene, the addition of turpentine oil can be detected by distilling the first fifth of the oil over, and testing it for pinene by means of the nitrosochloride reaction. The amount of phenols present can be ascertained approximately by shaking them out with 5 per cent. potassium hydroxide solution (see page 1047).

Action and Uses.—Because of its fragrance, oil of bay is used as a perfume. The drug is rarely if ever employed in internal medicine.

OLEUM MYRISTICÆ, *U. S., Br.*—Oil of Nutmeg.

I. *Oleum myristicæ æthereum, Oleum nucis moschati.—Volatile oil of nutmeg*, E.; *Essence de muscade*, Fr.; *Aetherisches Muskatnussöl*, G.; *Essencia de nuez moscada*, Sp.

II. *Oleum macidis.—Volatile oil of mace*, E.; *Essence de macis*, Fr.; *Macisöl, Muskatblüthenöl*, G.

Myristica fragrans Houttuyn (Fam. *Myristicaceæ*) yields two drugs:

a. The nutmeg, the seed of *M. f.* deprived of its testa; and *b.* The mace, the arillus.

The volatile oil of the former is designated Oleum myristicæ æthereum by continental writers in order to distinguish it from the fatty oil obtained by expression. So far as is known, oil of nutmeg and oil of mace contain the same constituents, but the former contains a larger percentage of terpenes than the latter, nevertheless the P. G. recognizes the oil from nutmeg under the title of oil of mace. Upon distillation, nutmegs yield 8–15 per cent., mace 4–15 per cent., of volatile oil.

Properties.—Oils of nutmeg and mace are colorless or yellowish, darkening with age, and possess the peculiar odor of the drugs from which they are obtained. The specific gravity of oil of nutmeg varies between 0.865 and 0.920, that of mace between 0.890 and 0.930. The specific gravity requirement of the U. S. P. is 0.862–0.910 at 25° C. (77° F.), that of the Br. 0.870–0.910, and that of the P. G. 0.890–0.930. Such wide limits are unfortunate, since the specific gravity is one of the principal criterions of the oil, but appear to be demanded, in part owing to the variable composition of the oil, in part to the changes which it is apt to undergo. The angle of rotation of oil of nutmeg varies between +14° and +28°, that of oil of mace between +10° and +20°. Both oils form a clear solution with 3 parts of 90 per cent. alcohol.

Composition.—The known constituents of both oils are pinene, dipentene, myristicol, myristicin or its isomer, a phenyl ether, and more or less of myristinic acid, according to the duration of the process of distillation. As stated above, oil of nutmeg contains a larger percentage of terpenes than does oil of mace.

Tests.—When 2 or 3 Cc. of this oil are evaporated in a capsule on a water-bath, no residue should be left which crystallizes on cooling, resembling the fatty oil of nutmeg.

Action and Uses.—This oil may be employed for the same purpose as nutmeg. It is rarely used in medicine. The dose is from 1 to 3 minims (0.05–0.20 Cc.).

OLEUM NUCISTÆ, *P. G.*—Expressed Oil of Nutmeg.

Oleum myristicæ expressum, Butyrum myristicæ, Butyrum nucistæ. Nutmeg butter, E.; *Beurre de muscade,* Fr.; *Muskatnussöl, Muskatbutter,* G.; *Manteca de nuez moscada,* Sp.

A mixture of the fixed and volatile oils of nutmeg, together with coloring-matter.

Preparation.—This oil is obtained in the East Indies by beating nutmegs into a paste, which is expressed between heated plates. The yield is about 28 per cent., and the annual importation into the United States is usually between 300 and 500 pounds. It is often incorrectly called *oil of mace.*

Properties.—It is found in commerce in the shape of blocks about 6 Cm. (2½ In.) thick and 25 Cm. (10 In.) long, and is wrapped in palm-leaves. It is solid and firm, unctuous to the touch, of a mottled appearance, orange-brown and whitish in color, of specific gravity 0.995, and has the fragrance and aromatic but bland taste of nutmegs. It melts at about 45° to 51° C. (113°–123.8° F.), and is soluble in 2 parts of warm ether and 4 parts of boiling strong alcohol (Lecanu).

Constituents.—Cold alcohol dissolves about 6 per cent. of volatile oil and 24 per cent. of fat, accompanied by brown-yellow resinous matter, which has not been further examined. The remaining pulverulent white fat is *myristin*, $C_3H_5(C_{14}H_{27}O_2)_3$, which crystallizes from hot alcohol or ether and fuses at 55° C. (131° F.). Schmidt and Rœmer (1883) found 3 to 4 per cent. of free myristic acid, with a little stearic acid.

Adulterations.—Artificial mixtures made from animal fats are not soluble in the same amount of hot alcohol, and the portion insoluble in cold alcohol would be more or less greasy.

Pharmaceutical Preparation.—*Balsamum nucistæ* (P. G.). Melt together yellow wax 1 part, olive oil 2 parts, and expressed oil of nutmeg 6 parts; pour into paper capsules and cut into square cakes.

Action and Uses.—Expressed oil of nutmeg may be employed as a vehicle for more active remedies. It is occasionally employed alone as an embrocation in the treatment of chronic rheumatism.

Allied Fats.—Becuiba Tallow is expressed from the seeds of *Myristica Becuhyba* Schott, s. *M. officinalis* Mart., which is indigenous to Brazil. The fat resembles the official article, but has a sharp, acidulous taste, melts at 47° C. (116.6° F.), and on treatment with cold absolute alcohol leaves 45 per cent. of yellow pulverulent residue undissolved.

Otoba Butter is prepared from *Myristica Otoba* Humb. et Bonpl., indigenous to Northwestern South America. It is yellowish, becomes brown by age, melts at 38° C. (100.4° F.), and has then an unpleasant odor. Its myristin melts at 46° C. (114.8° F.), and contains *otobit*, which is sparingly soluble in cold alcohol, crystallizes in colorless, inodorous, and tasteless prisms, and melts at 133° C. (271.4° F.) (Uricoechea, 1854).

Virola Tallow, Ocuba Wax, is prepared from *Virola* (*Myristica* Swartz) *sebifera* Aublet, indigenous to Guiana. The fat is yellowish, somewhat crystalline, completely soluble in alcohol, and melts at 45°–50° C. (113°–132° F.).

OLEUM OLIVÆ, *U. S., Br.*—Olive Oil.

Oleum olivarum, P. G.—*Sweet oil,* E.; *Huile d'olive,* Fr.; *Olivenöl,* G.; *Aceite de olivas,* Sp.

The fixed oil expressed from the ripe fruit of *Olea europæa* L. (Fam. *Oleaceæ*).

Origin.—In its wild state the olive is almost shrubby, much branched, and thorny, but under cultivation it is a medium-sized tree. It is indigenous to Western Asia, particularly Syria, and has been cultivated for a long time in the countries bordering on the Mediterranean. It has been introduced into the Southern United States, California, and several South American and other countries. The tree has evergreen, opposite, shortly petiolate leaves, which are lanceolate, acute at both ends, entire and revolute on the margin, and densely scaly, silvery gray, brownish or glaucous green beneath. The numerous small white flowers are in axillary racemes, diandrous, have a 2-celled and 4-ovuled superior embryo, and produce a purplish-black ovate drupe with a greenish, firm sarcocarp and an obliquely oblong-keeled putamen containing a single albuminous seed.

The leaves and bark have been employed in France as a febrifuge. De Luca (1861, etc.) found the leaves and green fruit to contain mannite, which diminishes in the latter as the fruit ripens, and disappears entirely when it becomes perfectly ripe. It contains then the largest amount of oil, equal in weight to nearly 70 per cent. of the sarcocarp.

Fig. 291.

Olea europæa L.

The "Pigale," "Verdale," "Rouget," "Picholine," "Sayern," "Pendoulier," and "Cailletier" are the principal varieties of olive tree grown for the production of olive oil in France.

Preparation.—The finest quality of olive oil is obtained by crushing the recently collected ripe olives in a suitable mill to a pulpy mass, care being taken in some districts not to break the putamen containing the seed; the pulpy mass is then subjected to moderate pressure, the oil, called *virgin oil* (*Huile vierge*, Fr.; *Jungfernöl*, G.), being collected in cisterns containing water, from the surface of which it is subsequently skimmed. The press-cakes are afterward thoroughly mixed with water and the marc again expressed, using an increased pressure, whereby a second quality of oil is obtained; in some places cold water is first used for softening the press-cakes, and is followed by hot water. However, with the improvements in the construction of powerful presses this portion of the process is much simplified, and a larger yield of oil of fine quality is obtained. The oil still remaining in the marc is said to amount to between 9 and 12 per cent., and is extracted by means of carbon disulphide; or the marc is thrown into cisterns, which in southern France are called *enfer*, and where an oil called *huile d'enfer*, having a disagreeable odor, separates upon the water. A larger amount of oil, but much inferior in quality, is yielded by expressing olives which have been kept in heaps and undergone a kind of fermentation; this oil is known in France as *huile fermentée;* and a still more inferior oil is prepared by again mixing the residue with boiling water and expressing. Though the seeds have a bitterish taste, Flückiger found the oil to be quite bland, to be a non-drying oil, and, if extracted with the oil of the fruit, to constitute about one-fortiêth of the latter.

Robert P. Skinner ("Olives and Olive Oil in France," adv. sheets of Consular Reports, No. 1639, May 6, 1903) summarizes the production of olive oil as follows: "1. Olives picked late yield a white oil of inferior quality. 2. Olives gathered at the precise moment of maturity give a maximum quantity of oil and the quality is normal. 3. Olives gathered a little before complete maturity produce a fine amber-colored oil, of superior quality, fruity in flavor, but diminished in quantity." To produce an oil combining perfume, finesse, and sweetness, "the product must be stored until the strong flavor has disappeared, the fruity flavor remaining dominant. To do this it is necessary to choose fruit that is but slightly ripe, and to place upon the market an oil that has been manufactured 6 or 8 months." (M. Anastay.)

The virgin oils are the product of the first or lightest pressure applied to the cold pulp.

Olive oil enters commerce put up in bottles of various sizes, also in stone jugs and in barrels.

Properties.—Olive oil is a pale-yellow or greenish-yellow oily liquid, having a neutral reaction, a slight agreeable odor and a bland taste, leaving, even in its freshest condition, a slight sense of acridity, which is somewhat increased on keeping. Its specific gravity at 15° C. (59° F.) is from 0.915 to 0.918 (P. G.), 0.914 to 0.919 (Br.), and at 25° C. (77° F.) 0.910 to 0.915 (U. S.). At and below 10° C. (50° F.) olive oil separates white crystalline granules; near 2° C. (35.6° F.) it is of a butyraceous consistence; and it congeals completely at or below the freezing-point of water, yielding, however, by strong pressure, from 67 to 72 per cent. of liquid oil, which remains fluid at —10° C. (14° F.), and is nearly pure *olein.* The solid portion fuses between 20° C. (68° F.) (Pelouze and Boudet) and 28° C. (82.4° F.) (Lecanu), and is easily soluble in ether. Olive oil is sparingly soluble in alcohol, freely soluble in ether, soluble in all proportions in chloroform, benzene, benzin, and carbon disulphide, and in about 5 parts of acetic ether. It does not readily become rancid, and belongs to the non-drying oils.

When heated to 120° C. (248° F.) it becomes lighter, and at 220° C. (428° F.) nearly colorless, and at the same time rancid; it commences to boil at about 315° C. (600° F.).

Inferior qualities of olive oil are of a deeper hue, become cloudy, and congeal more easily, have a more decidedly acrid after-taste, and turn rancid on exposure.

The German Pharmacopœia recognizes two qualities of olive oil—the one intended for internal use and for ointments, the other used for the preparation of plasters:

Oleum Olivarum, s. Oleum Provinciale.—*Best olive oil*, E.; *Huile d'olive fine*, Fr.; *Provenceröl*, G.—It is the oil described above.

Oleum Olivarum Commune.—*Olive oil*, E.; *Huile d'olive ordinaire*, Fr.; *Baumöl*, G.—This is the second quality of salad oil, has a brownish-yellow or green-yellow color, and, except a somewhat less pleasant odor and taste, agrees with the preceding.

Composition.—Olive oil is composed of about 72 per cent. of liquid glycerides (a mixture of linolein 6 and olein 94 per cent.) and about 28 per cent. of solid glycerides, consisting chiefly of palmitin with small quantities of arachin. Besides these, it is said by Holde and Stange (*Ber. d. D. Chem. Ges.*, 1901, p. 2402) to contain about 1.5 per cent. of a solid glyceride having an iodine value of 30 and a saponification value of 196.1. Stearic acid is stated by Hehner and Mitchell not to exist in olive oil. The unsaponifiable matter present, formerly supposed to be cholesterin, has been shown by Bomer and Soltsien (1901) and Gill and Tufts (*J. A. Ch. S.*, 1903) to consist of phytosterin. The greenish color of the oil is due to chlorophyll derived from the olive fruit.

Adulterations.—Olive oil has been found adulterated with groundnut oil, cottonseed oil, rapeseed oil, sesame oil, and at times with poppyseed oil. The absence of the properties mentioned above, together with the tests given below, will serve to detect these adulterations, which are rarely present in less quantity than 25 per cent. L. M. Tolman (*Proc. Amer. Pharm. Assoc.*, 1904, p. 382) recommends that, inasmuch as olive oil contains an impurity which interferes with the tests for cottonseed oil and sesame oil, it should be treated as follows: Place 25 to 30 Cc. of the oil in a separatory funnel and shake thoroughly with hot alcohol, allow to separate, remove the alcohol, and wash with hot water, and use this oil for the tests. The exact nature of the impurity removed by this method has not yet been determined. The same writer suggests that in making the test for cottonseed oil with a mixture of carbon disulphide and amyl alcohol, as recommended by the U. S. P., the salt-water bath should boil at from 112° to 115° C., and the test kept at this temperature for from 1 to 2 hours. Cottonseed oil, which has been heated, responds to this test only after 1 or 2 hours, and would escape detection during the shorter period of time directed in the official test.

Tests.—If 2 Cc. of olive oil be shaken vigorously with an equal volume of nitric acid of 1.37 specific gravity, the oil should retain a light-yellow color, not becoming orange or reddish brown, and after standing for 6 hours should change into a solid yellowish-white mass and an almost colorless liquid (absence of appreciable quantities of cottonseed oil and most other seed oils). If 5 Cc. of the oil be thoroughly shaken in a test-tube with 5 Cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 Cc. of alcohol and adding 2 drops of nitric acid) and the mixture heated for about 5 minutes on a water-bath, the oil should retain its original pale color, not becoming reddish or brown, nor should a dark color be produced at the line of contact of the two liquids (absence of more than about 5 per cent. of cottonseed oil). If 2 Cc. of the oil be mixed in a test-tube with 2 Cc. of a mixture of amyl alcohol and carbon disulphide containing 1 per cent. sulphur in solution, and this test-tube be immersed to a depth of $\frac{1}{3}$ to $\frac{1}{2}$ in boiling salt water, no reddish color should develop in from 10 to 15 minutes (absence of cottonseed oil). If 2 Cc. of the oil are mixed with 1 Cc. of hydrochloric acid (1.18 specific gravity) containing 1 per cent. of sugar, and the mixture shaken for $\frac{1}{2}$ minute and allowed to stand for 5 minutes, and then 3 Cc. of water added and again shaken, the acid layer should not show a pink color (absence of sesame oil). Olive oil, saponified by alcoholic potassium hydroxide test-solution, should show a saponification value of 191 to 195. If 0.3 Gm. of olive oil be dissolved in 10 Cc. of chloroform and placed in a 250-Cc. flask with 25 Cc. of a mixture of equal parts of alcoholic iodine test-solution and alcoholic mercuric chloride test-solution, and after standing for 4 hours protected from light, 20 Cc. of potassium iodide test-solution be added and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate solution, an iodine value of not less than 80 nor more than 88 should be obtained.—U. S. If 1 part of olive oil be agitated with 2 parts of a cold mixture

prepared from equal volumes of strong sulphuric acid and of nitric acid of 1.185 specific gravity, and the mixture set aside for ½ hour, the supernatant oily layer should not have a darker tint than yellowish or slightly greenish; sesame oil under the same conditions turns reddish or red; groundnut oil, reddish brown; cottonseed oil, dark red; sunflower oil, orange yellow.

Peanut, or groundnut, oil is perhaps more extensively used than some other oils to adulterate olive oil, and its presence is more difficult to detect since its physical and chemical constants are very similar to those of olive oil, and there is no color-reaction for its detection in small amounts. The following method used in the Bureau of Chemistry of the Agricultural Department at Washington, D. C., is said by Tolman to give very satisfactory results:

Weigh 20 Gm. of oil into an Erlenmeyer flask. Saponify with alcoholic potash, neutralize exactly with dilute acetic acid, using phenolphthalein as indicator, and wash into a 500-Cc. flask containing a boiling mixture of 100 Cc. of water and 120 Cc. of a 20 per cent. lead acetate solution. Boil for 1 minute, and then cool the precipitated soap by immersing the flask in water, occasionally giving it a whirling motion to cause the soap to stick to the sides of the flask. After the flask has cooled, the water and excess of lead can be poured off and the soap washed with cold water and with 90 per cent. (by volume) alcohol. Now add 200 Cc. of ether, cork the flask, and allow to stand for some time until the soap is disintegrated, then heat on the water-bath, using a reflux condenser, and boil for about 5 minutes. In the case of oils most of the soap will be dissolved, while in lards, which contain so much stearin, part will be left undissolved. Cool the ether solution of soap down to from 15° to 17° C., and let stand until the insoluble soaps have crystallized out—about 12 hours are required.

Filter and thoroughly wash the precipitate with ether. The soaps on the filter are washed back into the flask by means of a stream of hot water acidified with hydrochloric acid. Add an excess of dilute hydrochloric acid, partially fill the flask with hot water, and heat until fatty acids form a clear, oily layer. Fill the flask with hot water, allow the fatty acids to harden and separate from the precipitated lead chloride; wash, drain, repeat washing with hot water, and dissolve the fatty acids in 100 Cc. of boiling 90 per cent. (by volume) alcohol. Cool down to 15° C., shaking thoroughly to aid crystallization. From 5 to 10 per cent. of peanut oil can be detected by this method, as it effects a complete separation of the soluble acids from the insoluble, which interfere with the crystallization of the arachidic acid. Filter, wash, and precipitate twice with 10 Cc. of 90 per cent. (by volume) alcohol, and then with alcohol of 70 per cent. (by volume). Dissolve off the filter with boiling absolute alcohol, evaporate to dryness in a weighed dish, dry, and weigh. Add to this weight 0.0025 Gm. for each 10 Cc. of 90 per cent. alcohol used in the crystallization and washing, if done at 15° C.; if done at 20° C., 0.0045 Gm. for each 10 Cc. The melting-point of arachidic acid obtained in this way is between 71° and 72° C. 20 times the weight of arachidic acid will give the approximate amount of peanut oil present.

The best qualities of olive oil are imported from France. The total importations into the United States have been on a constant increase during the past few years, the importations being as follows:

	1899.	1900.	1901.	1902.	1903.[1]
Gallons	930,042	967,702	983,059	1,339,097	1,247,281
Valued at	$1,090,250	$1,170,871	$1,266,293	$1,579,409	$1,440,991

Action and Uses.—Olive oil is one of the blandest of vegetable oils, and is constantly used as a food and sometimes as a medicine. In the dose of from 1 to 2 ounces (30–60 Cc.) it acts as a mild laxative, but its use for this purpose is usually confined to infants, to which class of patients it is commonly given in the dose of from 1 to 2 teaspoonsful (4–8 Cc.). Because of its bland qualities and pleasant taste, it may be given when it is desired to fatten a patient, providing his digestion is capable of dealing with oils. Certain practitioners have great confidence in the value of olive oil in the treatment of gall-stones. Under these circumstances the dose is from ½ to 1 pint, and it is claimed that these quantities will often cause a discharge of gall-stones which have been giving the patient much trouble. How the oil acts under these circumstances is not known. It is very doubtful whether the instances in which it has seemed to do

[1] For the 10 months of the fiscal year 1903 ending April.

good have not been cases of coincidence rather than actual therapeutic activity. Olive oil is sometimes dropped into the external ear for the purpose of destroying insects which have entered the meatus. It is also applied externally as a soothing application to burns and various forms of cutaneous irritation. Mixed with lime-water in equal parts it forms the so-called "Carron oil" or *linimentum calcis.* Some cases of constipation derive much benefit by the injection into the bowel of from 4 to 8 ounces (120–240 Cc.) of olive oil at bedtime, the oil being retained until the next morning, during which period of retention it softens the feces. It is interesting to note that at one time surgeons were in the habit of dipping surgical instruments in hot olive oil before making an incision, with the idea that the oil exercised some curative property, but we now know that the heat in the oil sterilizes the knife, and that the oil itself has no curative effect.

OLEUM PALMÆ.—Palm Oil.

Huile (Beurre) de palme, Fr.; *Palmöl, Palmbutter,* G.; *Aceite de palma,* Sp.

A fixed oil obtained from the fruit of *Elæis guineensis* Jacq. (Fam. *Palmæ*).

Origin.—The oil-palm is a tall tree indigenous to Western Africa and introduced into other tropical countries. It has large pinnate leaves with spiny petioles and long, narrow linear leaflets. The fruit is a yellow mottled drupe about 25 Mm. (1 In.) long, and contains a leathery very oily sarcocarp, from which the fat is obtained by pressure or by boiling with water. The kernel yields likewise a bland oil which is white and melts at 25° C. (77° F.).

Properties.—Palm oil is solid at low temperatures, butyraceous, of a reddish-yellow color, and when fresh of an agreeable violet-like odor, and fuses at 27° C. (80.6° F.). On keeping, it becomes lighter in color and acquires a rancid odor, a portion of the fat being decomposed into free acids and glycerin, the fusing-point rising at the same time, sometimes to 42° C. (107.6° F.). When rapidly heated to 240° C. (464° F.) it is bleached. It is partly soluble in alcohol, but entirely so in ether. Its specific gravity is 0.945.

Composition.—It consists chiefly of tripalmitin and triolein, and contains a peculiar ferment, inducing its decomposition. The solid fatty acids consist of 98 per cent. of palmitic, 1 per cent. of stearic, and 1 per cent. of a heptadecylic acid, $C_{17}H_{34}O_2$ (Nördlinger, 1892). It is largely used in the preparation of soap; and to obtain the latter white, the oil is bleached by treating it with a solution of potassium dichromate and adding sufficient sulphuric and hydrochloric acids to form potassium sulphate and chromic chloride. The bright-reddish-yellow coloring-matter quite characteristic of palm oil is *lipochrome.* The iodine value of the fat is 51 to 52.5. The melting-point of the fatty acids is 47.8° to 50° C. (118°–120° F.) and the congealing-point is 45° to 36° C. (113°–96.8° F.).

Action and Uses.—It has recently come into use for coloring oleomargarine.

Other Palm Oils.—(See also OLEUM COCOIS.) MACAJA BUTTER, obtained from the seeds of *Cocos aculeata* Jacquin, of tropical America, has a yellowish color and a violet-like odor.

TUCUM OIL, from the fruit of *Astrocaryum vulgare* Mart., of South America, has a bright-red color and an agreeable odor.

OLEUM PAPAVERIS, *P. G.*—Poppy Oil.

Poppyseed oil, Maw oil, E.; *Huile de pavot, Huile d'œilette, Huile blanche,* Fr.; *Mohnöl,* G.

Source.—Oil of poppyseed is obtained by expression from the seed of *Papaver somniferum* L. (Fam. *Papaveraceæ*), which yields about half its weight of oil, the greater part ($\frac{2}{3}$) being obtainable without heat.

Properties.—Poppy oil, when expressed cold, is colorless or of faint-yellow color, almost odorless, and possesses an agreeable taste. It belongs to the drying oils and thickens when exposed to the air in thin layers. The oil remains clear when cooled to 0° C. (32° F.), but congeals at —18° C. (—0.4° F.). It is soluble in its own weight of ether, in 8 parts of boiling or 30 parts of cold alcohol. Its saponification factor is 192 to 195 and its specific gravity at 15° C. (59° F.) is 0.924 to 0.937. If pure poppy

oil be mixed with half its weight each of sulphuric and nitric acids, the mixture assumes a brick-red color.

Constituents.—Poppy oil consists of the glycerides of oleic, palmitic, stearic, linolenic, and linolic acids, chiefly the last named. It is rarely adulterated, but if so, probably with sesame oil, which may be detected by means of the furfurol test (see OLEUM SESAMI).

The P. G. requires that 2 Cc. of poppy oil mixed with 1 Cc. each of fuming nitric acid and water shall not congeal even after long standing, and that the oil shall absorb not less than 130 nor more than 150 per cent. of iodine.

Uses.—The chief use of poppy oil is for culinary purposes, although it is also used in the preparation of emulsions, liniments, etc., on account of its bland taste and stability.

OLEUM PHOSPHORATUM, *Br., Fr. Cod.*—Phosphorated Oil.

Huile phosphorée, Liniment phosphoré, Fr.; *Phosphorhaltiges Oel*, G.

Preparation.—The British Pharmacopœia directs expressed oil of almond to be heated in a porcelain dish to about 149° C. (300° F.) and kept at this temperature for about 15 minutes, after which it is allowed to cool and then filtered through paper. Of the oil so prepared, 99 parts by weight are put into a stoppered bottle capable of holding a little more than this quantity, and to it is added 1 part of dry phosphorus. The bottle is immersed in hot water until the contents have acquired the temperature of 82.2° C. (180° F.), the stopper being removed several times to allow the expanded air to escape, after which the bottle is shaken until the phosphorus is entirely dissolved.

The French Codex directs 1 part of phosphorus to be dissolved in 95 parts of expressed oil of almond after the manner indicated above, after which 4 parts of ether are to be added. These directions are very similar to those given in the U. S. P. of 1890, except that the latter authority required the almond oil to be heated in a flask on a sand-bath to 250° C. (482° F.) and kept at that temperature for 15 minutes; after filtration 1 part of phosphorus is dissolved in 90 parts of the prepared oil and 9 parts of ether then added. When almond oil is thus heated, at first air and moisture are given off; afterward certain organic matters are destroyed, the oil becoming nearly colorless and separating, on cooling, a little flocculent matter, which is separated by filtration. It is important that translucent phosphorus be selected, and after weighing out the required quantity the same should be quickly dried between bibulous paper.

Phosphorated oil should be recently prepared and preserved in a dark, cool place, for in the course of time, and particularly if unduly exposed, oxidation of the phosphorus takes place.

Properties.—Phosphorated oil is a clear yellowish liquid having the characteristic odor of phosphorus, and in the case of the French and former U. S. P. preparation, also of ether. The British oil phosphoresces in the dark and produces white vapors in contact with air, which is not observed with the French oil on account of the presence of ether.

Action and Uses.—The oil forms a convenient method for exhibiting the phosphorus. It may be administered either in capsules or in emulsion. The dose is from 1 to 5 minims (0.05–0.3 Cc.).

OLEUM PICIS LIQUIDÆ, *U. S.*—Oil of Tar.

Huile (Essence) de goudron, Fr.; *Theeröl, Pechöl*, G.; *Esencia de alquitran*, Sp.

A volatile oily liquid distilled from wood-tar.

Preparation.—Wood-tar is subjected to distillation, and that fraction of the distillate which is lighter than water collected by itself.

Properties.—Oil of tar, recently distilled, is colorless, but gradually darkens, becoming yellowish, brownish, and dark red brown, and depositing a black product. The oil has a strong tar-like odor and taste, an acid reaction, and a density of about 0.965 at 25° C. (77° F.); these properties are, however, subject to variation from differences in the composition of the tar. Alcohol readily dissolves it, yielding an acid solution.

Composition.—The oil is a mixture of various hydrocarbons and phenols of acetic and other acids, and of undetermined empyreumatic products present in tar; prepared from tar of coniferous woods, the oil consists largely of oil of turpentine.

Action and Uses.—The uses of this oil are practically the same as those of tar. In the form of an ointment, or diluted with some fluid oil, it is largely employed in the treatment of dry, scaly skin diseases.

OLEUM PIMENTÆ, *U. S., Br.*—Oil of Pimenta.

Oleum amomi; Oil of pimento (Br.), *Oil of allspice*, E.; *Essence de piment*, Fr.; *Pimentöl, Nelkenpfefferöl*, G.

The volatile oil distilled from *Pimenta officinalis* Lindl. (Fam. *Myrtaçeæ*), yielding, when assayed by the process given below, not less than 65 per cent. of eugenol.—U. S.

Allspice consists of the unripe berries, the ripe fruit containing a sweet jelly, but little or no aromatic substances. Upon distillation it yields 3 to 4.5 per cent. of oil.

Properties.—Oil of pimenta is a colorless, yellow, or reddish liquid (yellow or yellowish red when recently distilled, but gradually becoming darker, Br.). It has a strong, aromatic odor of allspice and a pungent spicy taste. Specific gravity: 1.033 to 1.048 at 25° C. (77° F.) (not below 1.040, Br.).—U. S. According to other authorities, its specific gravity varies between 1.024 and 1.050. The oil is slightly lævogyrate, and is miscible with 90 per cent. alcohol in all proportions; it also forms a clear solution with twice its volume of 70 per cent. alcohol.

Composition.—Pimenta oil contains eugenol and probably a sesquiterpene. Of the other constituents that give it its peculiar allspice odor nothing is known.

Tests.—When mixed with an equal volume of a concentrated solution of sodium hydroxide (strong solution of ammonia. Br.), it should form a semisolid mass. Its eugenol content can be ascertained by the following method of assay: "Introduce into a flask with a long neck (graduated in $\frac{1}{10}$ Cc.) 10 Cc. of the oil of pimenta and 100 Cc. of potassium hydroxide test-solution, and shake the mixture for 5 minutes. When the liquids have separated completely, add sufficient potassium hydroxide test-solution to raise the lower limit of the oily layer to the zero mark of the scale, and note the volume of residual liquid, which should not measure more than 3.5 Cc., indicating the presence of at least 65 per cent. of eugenol."—U. S.

Action and Uses.—The properties of this oil are those of an aromatic stimulant and carminative. The dose is from 3 to 5 minims (0.3–0.6 Cc.).

OLEUM PINI, *Br.*—Oil of Pine.

Pine needle oil.—Latschenkieferöl, Krummholzöl, G.

The oil obtained by steam distillation from the leaves of *Pinus pumilio* Hænke (Fam. *Coniferæ*).

Of the several pine-needle oils, that of *Pinus sylvestris*, the true Scotch fir, was official in the Br. P. of 1885, but has been replaced in the new edition by that of *Pinus pumilio*, which is distilled on a commercial scale in the Tyrolese Alps.

Properties.—According to the Br. P., this oil should be colorless or nearly so and possess a pleasant aromatic odor and pungent taste. Specific gravity 0.865 to 0.870; angle of rotation = —5° to —10°.

Composition.—The oil contains but little *l*-pinene; also *l*-phellandrene, sylvestrene, bornyl acetate, and cadinene.

Tests.—According to the Br. P., not more than 10 per cent. should distil below 165° C. (329° F.). About 70 per cent. distils between 170° and 180° C. (338° and 356° F.). The amount of ester, calculated as bornyl acetate (compare saponification test on page 1043), is reported to vary between 5 and 7 per cent.

Action and Uses.—Oil of pine has been applied locally and given internally in the treatment of chronic rheumatic affections. Its principal employment is as an inhalant in bronchial affections. When added to ether it is said to allay the irritation and diminish the bronchial secretion which frequently become excessive during, or after, the production of anæsthesia by the latter drug.

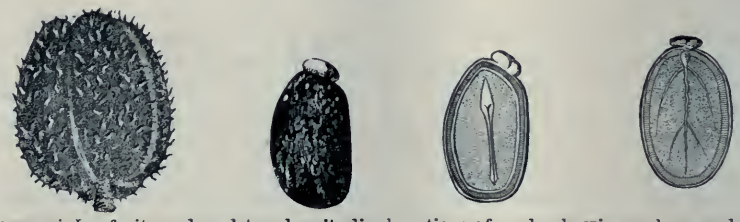
OLEUM RICINI, *U. S., Br., P. G.*—Castor Oil.

Oleum e semini ricini, Fr. Cod.; *Oleum Palmæ Christi.—Huile de ricin*, Fr.; *Ricinusöl*, G.; *Aceite de ricino*, Sp.

The fixed oil expressed from the seeds of *Ricinus communis* L.; *R. vulgaris* Mill.; *R. medicus* Forsk.; *Cataputia minor* Ludw. (Fam. *Euphorbiaceæ*).

Origin.—The castor-oil plant appears to be indigenous to Southern Asia, but was early introduced into all tropical and subtropical countries, in many of which it has become naturalized. It is often cultivated in temperate countries for ornament and other purposes, growing as a large annual. Numerous varieties are now known, differing from one another in size and color of the stem and foliage, as well as of the fruit and seeds. The leaves are alternate, peltate, palmately 7- or 9-lobed; the inflorescence is paniculately spicate, terminal, finally axillary; the flowers are monœcious, apetalous, the staminate ones at the base of the panicle. The fruit is a subglobular, somewhat triangular, and grooved tricoccous capsule, which is sometimes nearly smooth, but mostly spinescent; each cell encloses a single oval or elliptic seed, which is from 8 to 16 Mm. ($\frac{1}{3}$ to $\frac{2}{3}$ In.) long, 4 to 8 Mm. ($\frac{1}{6}$ to $\frac{1}{3}$ In.) broad, flattened on one side, smooth, shining, of a gray color variegated with yellowish, brown, or reddish spots and lines, with a slightly-raised raphe along the flattish side and a prominent caruncle near one end; this, when detached, leaves a slight depression above the hilum. The testa is hard, but brittle; the inner seed-coat is thin, white, and has a brownish chalaza; the embryo is

FIG. 292.



Ricinus communis L.: fruit, seed, and two longitudinal sections of seeds, showing embryo and albumen; natural size.

straight, white, has broad, foliaceous heart-shaped cotyledons, and is imbedded in an oily albumen having a bland scarcely acrid taste.

Preparation.—Nearly all the oil which is at the present time consumed in the United States is manufactured from seeds grown in the country or imported. The seeds, after having been crushed and freed from integuments, particular care being taken to remove all of the dark skin, are dried and expressed at a temperature not exceeding 60° C. (140° F.). The expressed oil is heated with water to remove albuminous matter, and when clear is drawn off into barrels or other suitable vessels. In India the best oil is produced by expression by means of hand-screws, the hydraulic presses giving a higher yield, but poorer quality (see *Proc. Am. Pharm. Assoc.*, 1900). Considerable quantities of castor oil of superior quality, being free from the usual unpleasant odor and taste, are produced in Italy. The secret of superiority is said to lie in the fact that only fresh seeds are used, and these are carefully freed from the integuments before being warmed and expressed. Over 300,000 bushels of castor beans and nearly 4000 gallons of castor oil were imported into this country during 1902. The yield is stated to be between 38 and 45 per cent., by cold pressure 25 to 30 per cent. More oil, but of inferior quality, is obtained by again expressing the marc and using a higher temperature and greater power; the additional yield is 6 to 8 per cent. Cold-pressed castor oil is nearly transparent, and requires no further purification. If opaque, the oil is clarified by filtration after treatment with fullers' earth, or a mixture of magnesia and purified animal charcoal. The press-cake resulting from the operation of extracting the oil is used principally as a fertilizer. It amounts to about 60 per cent. of the seed. Attempts are being made to utilize it as a cattle-food by first extracting the poisonous principle, *ricin*, by means of a 10 per cent. solution of salt, and drying the washed cake. Ricin is peculiar in being very poisonous to mankind but quite harmless to chickens.

Properties.—Castor oil is a viscid, transparent, almost colorless or pale-yellowish or greenish-yellow liquid, having a faint, mild, mawkish, but not repulsive odor, and a bland, afterward slightly acrid, and generally offensive taste. Its specific gravity at 15° C. (59° F.) varies between 0.950 and 0.970 (Br., P. G.) and between 0.945 and 0.965 at 25° C. (77° F.) (U. S.). At a low temperature it becomes thicker and turbid, depositing white granules or crystalline flakes at 0° C. (32° F.), and near

—18° C. (—0.4° F.) it congeals to a yellowish mass. It is soluble in its own volume of alcohol, and in all proportions of absolute alcohol or glacial acetic acid (U. S.); also soluble in 5 volumes (3 parts by weight, P. G.) of 90 per cent. alcohol (Br.). It yields with an equal volume of petroleum benzin a turbid mixture at 15° C. (59° F.), but a clear solution at 17° C. (65.6° F.) (U. S.), and is miscible with 1½ times its volume of petroleum or mineral oil (Draper). The oil has a neutral reaction to test-paper, but when exposed to the atmosphere in thin layers it becomes acid, and slowly dries to a transparent varnish-like film. In contact with nitrous acid castor oil becomes much thicker, and finally congeals, requiring a longer time than the non-drying oils, and when agitated with equal weights of nitric acid and water it yields a whitish mixture turning yellow in the presence of nitrous acid.

Adulterations.—Castor oil may be found adulterated with other fatty oils, such as cottonseed oil, rapeseed oil, and sesame oil, as well as mineral oils; their presence may be detected by decreased solubility in alcohol and the tests given below.

Tests.—If 3 Cc. of castor oil be shaken for a few minutes with 3 Cc. of carbon disulphide and 1 Cc. of sulphuric acid, the mixture should not acquire a blackish-brown color (absence of foreign oils). The oil is soluble at 15° C. (59° F.) in 3 times its volume of 92.5 per cent. alcohol (absence of more than about 5 per cent. of most other fixed oils). If 0.3 Gm. of castor oil be dissolved in 10 Cc. of chloroform and placed in a 250-Cc. flask with 25 Cc. of a mixture of equal parts of alcoholic iodine test-solution and alcoholic mercuric chloride test-solution, and after standing for 4 hours protected from light, 20 Cc. of potassium iodide test-solution be added, and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate solution, an iodine figure of not less than 86 nor more than 89 should be obtained (U. S.). The iodine value of castor oil is remarkably constant, and, according to Benedickt and Ulzer, is somewhat lower than that given by the U. S. P., being stated as 82–84. When castor oil is saponified with alcoholic solution of potassium hydroxide it will show a saponification value of 176–180 (U. S.).

Composition.—Castor oil consists principally of triricinolein ($C_3H_5(C_{18}H_{33}O_3)_3$), together with considerable ricinisolein (Hazura and Grüssner, *J. S. C. I.*, 1888), palmitin, and dihydroxystearin (H. Meyer, *J. C. S.*, 1897). According to Thoms and Fendler (*Archiv d. Pharm.*, 1901), the distillation of castor oil yields undecenoic acid and heptaldehyde, the temperature rising to 280° C. (536° F.), and when about one-half has distilled over, the residue suddenly swells, the mass acquiring the consistence of India-rubber.

Among other constituents besides the oil, such as water, nitrogenous matter, fibre, and mineral substances, castor beans or seed contain two substances that are deserving of more than passing notice, namely *ricin* and *ricinine.*

Ricin.—Attention was first called to this substance by Kobert and Stillmark, who designated it as an unorganized ferment belonging to the group of toxalbumins. Ricin is present in the seed to the extent of 2.8 or 3 per cent., and may be obtained from fresh decorticated and strongly expressed seed by percolation with a 10 per cent. salt solution, in which it is soluble. The percolate is filtered and saturated at 20° or 22° C. (68° or 72.6° F.) with magnesium and sodium sulphates, and set aside in a cool place. The resulting white precipitate is separated from the crystallized salts and subjected to dialysis for several days, in a cool room so as to prevent decomposition, the water being frequently renewed. As thus obtained, ricin is a white, odorless, strongly toxic, ash-yielding powder. It is insoluble in alcohol, ether, and chloroform. Its solution in salt solution gives the characteristic albumen reactions. Ricin is not affected by dry heat, but if heat be applied to its solution its toxic properties disappear. When taken internally, it acts as a violent irritant upon the gastro-intestinal tract, causing inflammation of the same and also of the mucous membrane of the biliary duct and of the bladder and kidneys. As little as 0.00003 Gm. per kilo of body-weight has been known to kill a dog. The lethal dose for man is supposed to be 0.030 Gm. by the mouth or 0.003 Gm. subcutaneously.

Ricinine.—In 1864 Tuson announced the discovery of a poisonous base in the seed of the castor-oil plant, to which the name ricinine was given, and which was further investigated by Marco Soave in 1875, who determined its composition to be $C_{17}H_{18}N_4O_4$. Ricinine is present to the extent of 0.15 per cent. in the seed-coats, and 0.03 per cent. in the oil-cake left as residue after expression of the seeds. It may be extracted as

follows: The material is extracted with boiling water, the resulting solution evaporated to dryness, and the residue exhausted with alcohol. After recovery of the alcohol, the dry extract is treated with very dilute sodium hydroxide solution for removal of certain impurities, and the residuary ricinine obtained in the form of rectangular prisms or plates by crystallization from hot water or alcohol. Ricinine melts at 194° C. (381.2° F.) and congeals at 175° C. (347° F.); it sublimes without decomposition, has a decidedly bitter taste, and is optically inactive. It readily dissolves in water, alcohol, chloroform, benzene, and ether, the solutions having a neutral reaction. When heated with potassium hydroxide, ammonia is evolved. Ricinine dissolves without color in cold sulphuric acid, but the addition of a few grains of potassium dichromate to the solution causes a yellowish-green color, which soon changes to intense green, whereby even traces of the substance may be detected. Hot sulphuric acid forms a red solution with ricinine. Mercuric chloride solution and Wagner's reagent (iodized potassium iodide solution) precipitate solutions of ricinine, but other alkaloidal reagents are without effect. Ricinine is not capable of forming salts with acids, and when treated with oxidizing agents yields ricinic acid, $C_{13}H_{12}(CO_2H)_2N_4$, a dibasic acid melting at 295° C. (563° F.); the same acid, together with methyl alcohol, is obtained if ricinine be saponified with sodium hydroxide, and hence ricinine is to be looked upon as the dimethyl ester of ricinic acid. Ricinine has recently been again investigated by Philippe and Maquerme, who assign the formula $C_8H_8N_2O_2$ to the purified base (*Proc. Amer. Pharm. Assoc.*, 1904, p. 950).

Besides its extensive use for medicinal purposes, castor oil is extensively employed for the manufacture of the so-called Turkish-red oil, used in calico dyeing and printing. Turkish-red oil is made by adding, very slowly, concentrated sulphuric acid drop by drop to 4 times its weight of castor oil contained in a capacious vessel surrounded by ice-water to prevent a rise of temperature. The mixture is stirred during the addition of the acid, and after 12 hours' rest is carefully washed with cold water, and after separation of the oily layer the latter is washed with 10 per cent. salt solution previously warmed to about 65° C. (149° F.), and finally nearly but not quite neutralized with ammonia-water or sodium hydroxide solution. The finished product is a thick yellow or yellowish-brown oily fluid, miscible with water in the form of an emulsion, from which oily drops separate only after long standing. It consists of a mixture of sulphoricinoleic acid ($C_{18}H_{33}O_2.OSO_3H$), free fatty acids, undecomposed oil. The French Pharmacopœia recognizes a similar preparation under the name *Linimentum sulforicinatum* or *Topique sulforicine*, which differs from the crude article in being completely dried by agitation with anhydrous potassium carbonate after removal of the aqueous layer, and is then filtered through paper: moreover, sodium hydroxide solution only is used as the neutralizing agent. This purer article is commercially also known as *polysolve*.

Under the name Castor Oil for Lubricating Purposes a mixture is offered for sale, containing no castor oil at all, which is merely a ropy mixture of mineral oil with the residue of cottonseed expression.

Action and Uses.—Castor oil owes its purgative properties somewhat to its oily character, chiefly, however, to the small amount of ricin it contains. It produces purgation in from 4 to 6 hours, accompanied, as a rule, by but little griping or tenesmus.

Because its action is so bland and unirritating it is the purgative of choice to unload the bowels of food which, through its decomposition, is causing inflammation attended by abdominal cramp or diarrhœa. It possesses the advantage over other purges used in irritative diarrhœa, in that after having swept the bowel of the mucus and offending material, it produces constipation and is frequently, therefore, the only remedy necessary. This after-constipating effect of the oil, and the fact that it tends to produce hemorrhoids if employed constantly, detract from its usefulness in chronic constipation.

In the constipation occurring in infants and children, and that following acute diseases, it is very efficacious. The idea that it decreases the severity of labor more than any other purge, if given previous to parturition, is erroneous.

Many methods have been devised to mask the unpleasant taste of castor oil. Certainly the most successful way is to administer it in soft capsules when these can be swallowed; each capsule to contain from 1 to 4 drachms (4–16 Cc.) of the oil. Some prefer it suspended in sarsaparilla soda water, others in milk or cream, or in the froth of beer or porter. A few drops of any of the aromatic oils, as peppermint, cinnamon, etc., disguise the taste fairly well, and possess the additional advantage of preventing the griping that may otherwise occur. For the latter purpose a teaspoonful of paregoric

or a few drops of laudanum, of tincture of belladonna, are frequently employed. The dose of castor oil for an infant is from 1 to 2 drachms (4–8 Cc.), for an adult, ½ to 1 ounce (16–30 Cc.).

Allied Oils.—Omphalea Oil.—The fixed oil expressed from the seed of *O. megacarpa* Hemsl. is found by Hart to be a valuable substitute for castor oil as a mild purgative. The seed possesses a hard, rough, black, rather brittle testa and a bland and fatty kernel, and is enclosed in a fruit-pulp which is very starchy. The flavor of the kernel is pleasant, and it is said that half of the oil extracted from one seed is effective, and that it does not gripe.

The oil of *O. oleifera* Hemsl. is similarly used in Central America under the name *Tamboe Oil.*

OLEUM ROSÆ, *U. S., Br., P. G.*—Oil of Rose.

Oleum rosarum.—Attar or otto of roses, E.; *Essence de rose,* Fr.; *Rosenöl,* G.

A volatile oil distilled from the fresh flowers of *Rosa damascena* Müller (Fam. *Rosaceæ*), having, when assayed by the process given below, a saponification value of not less than 10 nor more than 17. It should be kept in well-stoppered, amber-colored vials in a cool place, protected from light. When dispensed it should be completely liquefied by warming, if necessary, and well mixed by agitation.—U. S.

The oleum rosarum, ol. rosatum, or ol. rosaceum, of the ancients, was not a volatile oil, but a fatty oil perfumed with rose-petals. Rose-water has for a long time played an important rôle in Oriental hygiene and medicine. The first reference to volatile oil of rose possibly dates back as far as the tenth century. During the sixteenth century it found a place in continental tax ordinances. The cultivation of roses in Bulgaria, which for a long time has been supplying the European and American markets, was begun about the beginning of the seventeenth century. In recent years roses have been cultivated successfully on a large scale in France and Germany. In Bulgaria the rose-petals are distilled with water, 3000 kilos of flowers yielding about 1 kilo of oil. The cultivation in Germany (Miltitz) was begun in 1883. From 5000 to 6000 kilos of flowers yield about 1 kilo of oil, the most modern apparatus and methods being used.

Properties.—Bulgarian oil of rose is light yellow in color, sometimes possessing a greenish tint. Between 21° and 25° C. (69.8° and 77° F.) it is of the consistence of sweet almond oil; below this temperature acicular crystals or shining laminæ separate out, which, on account of their lighter specific gravity, collect in the upper portion of the oil. When cooled, it congeals to a translucent soft mass, which is again liquefied by the warmth of the hand. It has a strong odor of fresh roses.

The specific gravity varies, as a rule, between 0.855 and 0.870 at 20° C. (68° F.), being lowered by an increasing stearoptene content. The specific gravity requirement of the U. S. P. is 0.855–0.865 at 25° C. (77° F.), that of the Br., 0.856–0.860 at 30° C. (86° F.); the P. G. states no such requirement. It is slightly lævogyrate, the angle of rotation = up to —4°. The congealing-point lies between 15° and 22° C. (59° and 71.6° F.), mostly between 17° and 21° C. (62.6° and 69.8° F.); U. S., 18° to 22° C. (64.4°–71.6° F.); Br., 19.4° to 22.2° C. (67°–72° F.); P. G., 18° to 21° C. (64.4°–69.8° F.).

The addition of 70 per cent. alcohol precipitates the paraffin hydrocarbons of the oil, but forms a clear solution with its other constituents, the solution being slightly acid to litmus test-solution. The acid number of the oil varies between 0.5 and 3, the saponification number between 10 and 17.

On account of its larger stearoptene content, German oil of rose, the odor of which is said to be stronger and more persistent, is at ordinary temperature a greenish mass intermingled with crystals. The congealing-point lies between 27° and 37° C., the specific gravity between 0.845 and 0.855 at 30° C. (86° F.); its angle of rotation = +1° to —1°.

French oils of 1895 and 1896 are reputed to have had the following properties: specific gravity 0.8225–0.8407 at 30° C. (86° F.); angle of rotation at 30° C. (06° F.) = —6° 45′ to —8° 3′.

Composition.—The first constituent of rose oil to be studied was the stearoptene, which was recognized as paraffin hydrocarbon by Flückiger. It evidently consists of a mixture of hydrocarbons. From the so-called eleoptene geraniol, *l*-linalool, citral, *l*-citronellol, *n*-nonylic aldehyde, and the solid phenyl ethyl alcohol (melting-point 80° C.) have been isolated thus far. On account of the greater solubility of this benzene alcohol

in water, the oil which separates from the water (commercial rose oil) contains much less of this substance than the oil extracted from rose-water with ether. The oil evidently also contains terpenes.

Adulteration and Tests.—The danger of adulteration of so expensive an oil as oil of rose has always been great, hence a large number of empirical tests have been suggested, the value of most of which is exceedingly problematic. The principal adulterants are palmarosa oil and true geranium oil, oils which have one or more constituents (geraniol) in common with oil of rose. The addition of these, either to the leaves before distillation or to the finished product, reduces the congealing-point. This can be brought up to the normal standard by the addition of spermaceti. Hence, in addition to the congealing-point, the determination of the absence of spermaceti in the stearoptene may become necessary. Another recent adulterant of importance is the guaiac wood oil.

Assay of Oil of Rose.—Place in a weighing bottle about 2 Cc. of the oil of rose, and weigh it accurately. Transfer it, with the aid of a little alcohol, to a 100-Cc. flask, and add 20 Cc. of half-normal alcoholic potassium hydroxide solution. Connect the flask with a reflux condensor, and boil the mixture during 30 minutes on a water-bath. When cool, add 50 Cc. of distilled water and a few drops of phenolphthalein test-solution, and titrate with half-normal sulphuric acid. Subtract the number of Cc. of half-normal sulphuric acid required from 20 (the 20 Cc. of half-normal alcoholic potassium hydroxide solution taken), multiply the difference by 27.87, and divide by the weight of the oil to obtain the saponification value.—U. S.

The saponification number of a good commercial oil varies from 10 to 17, the acid number from 0.8 to 2.7. Palmarosa oil, according to Gildemeister and Stephan, has a saponification number of 30–50, the genuine geranium oils 45–100. Additions of the latter may, therefore, become noticeable.

Congealing-point.—With reference to rose oil, it is that point at which the first crystals separate when the oil is slowly cooled.

About 10 Cc. of rose oil are introduced into a test-tube of about 15 Mm. diameter. A thermometer is so inserted that it touches neither the bottom nor the sides of the tube, but floats freely. The oil in the tubes is warmed 4–5 degrees C. above the saturation-point by means of the hand and well shaken. The tube is then securely supported and the oil allowed to cool spontaneously until the first crystals appear. At this point the temperature is read, and the operation repeated for confirmation.—U. S.

Stearoptene Assay.—50 Gm. of oil are heated to 70° to 80° C. (158°–176° F.) with 500 Gm. of 75 per cent. alcohol. When cooled to 0° the stearoptene separates almost quantitatively. It is separated by filtration, again treated with 200 Gm. of 75 per cent. alcohol, and the operation repeated until it has become perfectly odorless. As a rule two such treatments of the crude stearoptene suffice.

The spermaceti content of the stearoptene can be determined in a simple manner by saponifying the separated stearoptene with alcoholic solution of potassium hydroxide of known strength and titrating back with $\frac{N}{2}$ sulphuric acid. The saponification number of spermaceti is 108.

Acetylization.—In order to make the examination of the oil complete, it will often be advisable to ascertain the alcohol content (geraniol and citronellol) by acetylization. The amount present will be inversely proportional to the percentage of stearoptene present. Umney found 70–72.5 per cent. (calculated as geraniol) in good rose oil. Palmarosa oil contains 76–92 per cent. of geraniol.

As latest adulterant, guaiac wood oil from *Bulnesia sarmienti*, which has an agreeable, tea-rose-like odor, has been employed in Bulgaria. It can be recognized by the microscopic examination of the form of the crystals of guaiol which separate from the oil upon cooling. Guaiol forms needle-shaped crystals which are characterized by a channel-like middle line. The crystals of the rose oil paraffin are smaller and thinner and possess less sharply outlined forms.

The positive presence of guaiac wood oil in rose oil should be established by the isolation of guaiol melting at 91° C. The new adulterant increases the specific gravity and the optical rotation, and raises the congealing-point of the oil; it lowers the saponification number but very little, and upon evaporation leaves a resinous residue.

Action and Uses.—Oil of rose is employed in medicine for the purpose of perfuming cerates, ointments, and lotions.

OLEUM ROSMARINI, *U. S., Br., P. G.*—Oil of Rosemary.

Oleum anthos.—Essence de rosmarini, Fr.; *Rosmarinöl*, G.

A volatile oil distilled from the fresh flowering tops of *Rosmarinus officinalis* L. (Fam. *Labiatæ*), yielding, when assayed by the process given below, not less than 5 per cent. of ester, calculated as bornyl acetate, and not less than 15 per cent. of total borneol.—U. S.

There are two principal commercial varieties of this oil. The Italian, or rather Dalmatian oil, is distilled after the flowering season is over. The French, which possesses a finer odor, is distilled principally from the flowering tops. The English oil, which is obtained in small amounts from cultivated plants, and the Spanish oil, play a minor role commercially, though the former is highly esteemed by some, and commands a high price.

Properties.—Oil of rosemary is colorless or slightly greenish yellow in color, possessing the peculiar odor of rosemary. The specific gravity requirements are 0.894–0.912 at 25° C. (77° F.), U. S., 0.890–0.910, P. G., and 0.900–0.915, Br. All genuine oils are reported to have a specific gravity of more than 0.900, sometimes as high as 0.920. The oil should be dextrogyrate, but not more than +15° in a 100-Mm. tube at a temperature of 25° C. (77° F.), U. S. A greater rotation indicates American turpentine; but French turpentine reduces the angle of rotation or renders the oil lævogyrate, hence the first 10 per cent. of the distillate should be dextrogyrate as well. The oil should be soluble in one-half volume of 90 per cent. alcohol and in 2–10 parts of 80 per cent. alcohol.

Composition.—Of the constituents of rosemary oil, pinene, camphene, cineol, camphor, and borneol have been identified. The total amount of borneol present is 16–18 per cent.; about 5–6 per cent. are present as ester, calculated as acetate.

Tests.—The estimation of esters and free alcohols by saponification and acetylization with a second saponification yields valuable information. The results are expressed as borneol and bornyl acetate. The following method of assay is given in the U. S. P. The evaporation test may reveal the presence of high-boiling petroleum fractions. The detection of French turpentine has been alluded to. Larger yields than 15–20 per cent. distilling below 170° C. would indicate either French or American turpentine oil.

Assay of Oil of Rosemary.—Introduce into a tared flask 10 Cc. of oil of rosemary, and note the exact weight; add 25 Cc. of half-normal alcoholic potassium hydroxide solution, connect with a reflux condenser, and boil the mixture during 1 hour. After cooling, titrate the residual alkali with half-normal sulphuric acid solution, using phenolphthalein test-solution as indicator. Subtract the number of cubic centimeters of half-normal sulphuric acid solution required from the 25 Cc. of half-normal alcoholic potassium hydroxide solution taken, multiply the difference by 9.734, and divide the product by the weight of the oil of rosemary taken to find the percentage of bornyl acetate. Wash the residual oil repeatedly with water, transfer it to a flask provided with a ground-glass tube-condenser (acetylization flask), add 10 Cc. of acetic acid anhydride and about 1 Gm. of anhydrous sodium acetate, and boil gently during 1 hour. Allow it to cool, wash the acetylized oil with distilled water, and afterward with sodium hydroxide test-solution, until the mixture is slightly alkaline to phenolphthalein test-solution, and then dry it with the aid of fused calcium chloride, and filter. Transfer to a tared 100-Cc. flask 5 Cc. of the dry acetylized oil, note the exact weight, add 50 Cc. of half-normal alcoholic potassium hydroxide solution, connect with a reflux condenser, and boil the mixture during 1 hour. After cooling, titrate the residual alkali with half-normal sulphuric acid solution, using phenolphthalein test-solution as indicator. Subtract the number of cubic centimeters of half-normal sulphuric acid solution required from the 50 Cc. of half-normal alcoholic potassium hydroxide solution taken, multiply the difference by 7.649, and divide the product by the weight of the dry acetylized oil taken, less the above difference multiplied by 0.021; the quotient will represent the percentage of borneol in the oil of rosemary.

Note.—The difference referred to above represents the number of cubic centimeters of half-normal alcoholic potassium hydroxide solution consumed by the acetylized oil.—U. S.

Action and Uses.—In moderate amounts oil of rosemary acts as a stimulant, aromatic and carminative. It may be given internally to relieve flatulent colic, promote menstruation, and to overcome nervous depression. As a local application it is said to do good in the treatment of chronic rheumatism, sprains, etc. An ointment containing the oil may also be tried as a remedy for alopecia. The internal dose is from 1 to 3 minims (0.05–0.20 Cc.).

OLEUM SABINÆ, *U. S.*—Oil of Savin.

Essence de sabine, Fr.; *Sadebaumöl*, G.

Commercial savin oil is distilled from the fresh tops of Savin. The yield varies between 3 and 5 per cent., according to the time of collection and the freshness of the material. According to the present edition of the U. S. P., it is defined as being derived from the fresh tops of savin. It was formerly official in the Br., but was dropped from the last edition. Most of the oil is distilled in Tyrol. That distilled in France is reported to be obtained from *J. phœnicea*.

Properties.—Oil of savin is colorless or yellowish, and possesses a peculiar terebinthinate odor, and a pungent, bitterish, camphoraceous taste. Specific gravity varies from 0.903–0.923 at 25° C. (77° F.), and the angle of rotation between + 40° and + 60° in a 100-Mm. tube at the same temperature. It is soluble in about one-half of its volume of 90 per cent. alcohol.—U. S.

Composition.—The principal constituent is sabinol, an alcohol, $C_{10}H_{15}OH$, which is present in the free state to the extent of 10 per cent., and as ester to the extent of 40–44 per cent. The oil also contains a sesquiterpene and an aldehyde, possibly cuminic aldehyde.

Adulteration and Tests.—The most common adulterant is turpentine oil. At times other leaves are apparently substituted. Not more than 25 per cent. should distil over below 200° C. (392° F.). The ester number also ought to prove valuable, but it is claimed that the saponification numbers usually given (115–125) are based on insufficient data.

Action and Uses.—Oil of savin is a powerful uterine stimulant, and is said to be of value in the treatment of amenorrhœa, dysmenorrhœa, menorrhagia, and leucorrhœa. The dose is from 2 to 10 minims (0.10–0.6 Cc.).

OLEUM SANTALI, *U. S., Br., P. G.*—Oil of Santal.

Oleum ligni santali.—Oil of sandalwood, E.; *Essence de santal*, Fr.; *Ostindisches Sandelholzöl*, G.

The volatile oil distilled from the wood of *Santalum album* L. (Fam. *Santalaceæ*), yielding, when assayed by the process given below, not less than 90 per cent. of alcohols, calculated as santalol.—U. S.

The white sandalwood is a rather small tree indigenous to the mountains of India. It either grows wild or is cultivated in dry open places, rarely in forests, and is much used in cabinet-work. The territory which produces sandalwood is a strip 250 miles long, extending from the Nilgiri Mountains northward to Canares. Sandalwood is also produced in eastern Java and other islands (Macassar wood). The trees are the property of the State, and are cultivated in the government plantations of British India, the collection of the wood being controlled by legal provisions. The sap-wood is sometimes removed by cutting, sometimes by exposing it for several months to the attacks of termites. Owing to the difficulty of getting a pure oil of native distillation, large quantities of the wood are now imported for distillation in this country. It occurs in billets of a dirty light-brown color, the surface often irregular from the marks of the axe employed in hacking off the sap-wood. Occasionally it is imported in the form of chips or splinters, in which case much of the sap-wood is apt to be included. It is very heavy, hard, and tough-splintery. When rubbed or heated it exhales the delightful fragrance of its oil. If of fine quality, the splinters exhibit a pinkish-yellow tint which distinguishes them from the whitish sap-wood. It is then often designated as "Red Sandalwood," not to be mistaken for *Santalum Rubrum* or *Red Saunders*.

East India sandalwood yields from 3 to 5 per cent. of oil, the Macassar wood from 1.6 to 3 per cent.

Properties.—East Indian sandalwood oil is a rather viscid, yellowish liquid of peculiar faint but persistent odor, and of an unpleasant, resinous, harsh taste. The specific gravity of oil of santal varies from 0.965–0.975 at 25° C. (77° F.) U. S., 0.975–0.980, Br., 0.975–0.985, P. G. Its angle of rotation should not be less than —16° nor more than —20° in a 100-Mm. tube (showing the absence of other varieties of sandalwood oil), U. S., Br. It is soluble in from 5 to 6 parts of 70 per cent. alcohol.

The Indian oils usually are darker and have a higher specific gravity. But little of this oil is said to enter the European and American markets.

Composition.—The principal constituent or constituents of sandalwood oil are alcoholic in nature, and amount to 90 per cent. and more. These are commonly known as santalol, and the formula $C_{15}H_{25}OH$ is generally assigned to them. The oil is, likewise, supposed to contain an aldehyde santalal and a sesquiterpene or sesquiterpenes. The presence of several acids is also claimed by some investigators.

Adulterants and Assay.—The specific gravity, angle of rotation, and solubility tests are best supplemented by a santalol assay by means of acetylization and subsequent saponification. The effect of the more common adulterants upon the assay is best indicated by their acetylization numbers calculated as per cent. santalol: cedarwood oil, 8 to 12 per cent.; copaiba oil, 5 to 8 per cent.; gurjun balsam oil, 7 to 10 per cent. Castor oil, which is sometimes added as adulterant, has a very high saponification number.

Assay of Oil of Santal.—Introduce 10 Cc. of oil of santal into a flask provided with a ground-glass tube-condenser (acetylization flask), add 10 Cc. of acetic acid anhydride, and about 2 Gm. of anhydrous sodium acetate, and boil the mixture gently during 1½ hours. Allow it to cool, wash the acetylized oil with distilled water, and afterward with sodium hydroxide test-solution, until the mixture is slightly alkaline to phenolphthalein test-solution, and then dry it with the aid of fused calcium chloride, and filter. Transfer to a tared 100-Cc. flask 3 Cc. of the dry acetylized oil, note the exact weight, add 50-Cc. of half-normal alcoholic potassium hydroxide solution, connect with a reflux condenser, and boil gently during 1 hour. After cooling, titrate the residual alkali with half-normal sulphuric acid solution, using phenolphthalein test-solution as indicator. Subtract the number of cubic centimeters of half-normal sulphuric acid solution required from the 50 Cc. of half-normal alcoholic potassium hydroxide solution taken, multiply the difference by 11.026, and divide by the weight of the dry acetylized oil taken, less the above difference multiplied by 0.021; the quotient will represent the percentage of santalol in the oil of santal.

Note.—The difference referred to above represents the number of cubic centimeters of half-normal alcoholic potassium hydroxide solution consumed by the acetylized oil.—U. S.

The presence of chloroform may be detected in the following manner: If a small strip of filter-paper be folded in the form of a taper, saturated with oil of santal, placed in a small porcelain dish, and if a clean beaker, moistened on the inner surface with distilled water, be inverted over the smaller dish, after igniting the taper a part of the products of combustion will be absorbed by the water; if the beaker be then rinsed with a little distilled water and the liquid filtered, the filtrate should yield no turbidity upon the addition of a few drops of silver nitrate test-solution (absence of chlorinated products).—U. S.

Action and Uses.—Oil of sandalwood is used to some extent as a perfume. When given internally in moderate amounts it acts as a stimulant to the respiratory and genito-urinary mucous membranes, but in overdose is extremely irritating to the genito-urinary tract. It is used quite largely in gonorrhœa after the acute inflammatory condition has subsided. The remedy may also be successfully employed in subacute bronchitis and certain forms of asthma. The dose is from 5 to 20 minims (0.3–1.3 Cc.), given in capsule; the latter amount, however, may produce considerable lumbar pain.

OLEUM SASSAFRAS, *U. S.*—Oil of Sassafras.

Essence de sassafras, Fr.; *Sassafrasöl*, G.

A volatile oil distilled from the root, especially the root-bark, of *Sassafras variifolium* (Salisb.) O. Kuntze (Fam. *Lauraceæ*).—U. S.

The distillation of sassafras oil is an American industry. The principal States producing the oil are Virginia, Maryland, and Pennsylvania. During and after the civil war (1861–1865) considerable oil was also distilled in New Jersey, New York, Ohio, Indiana, Tennessee, and the New England States, until the practical extinction of the tree rendered the industry unprofitable.

Properties.—Sassafras oil is a colorless (rectified oil), yellowish, or reddish liquid (crude oil) having the specific gravity 1.065–1.075 at 25° C. (77° F.). The oil is dextrogyrate, but should not deviate the ray of polarized light more than +4° in a 100-Mm. tube at a temperature of 25° C. (77° F.). It is soluble in all proportions in 90 per cent. alcohol.—U. S.

Composition.—Safrol, which is likewise official as such, is the principal constituent, about 80 per cent. Pinene and phellandrene constitute about 10 per cent., *d*-camphor about 7 per cent., eugenol 0.5 per cent. The oil possibly also contains sesquiterpenes.

Adulteration.—Sassafras oil is frequently adulterated with camphor oil. A perfectly pure article appears to be of rare occurrence. Inasmuch as camphor oil contains all of the constituents found in sassafras oil, the detection of the former is exceedingly difficult, but its presence may be indicated by strong variations in the specific gravity and other physical properties. Under the name of artificial sassafras oil, fractions of camphor oil having a specific gravity similar to that of true sassafras oil are sold.

Action and Uses.—Oil of sassafras may be employed for the same purposes as the other volatile oils having a similar composition. In overdose it produces vomiting, collapse, and stupor. The dose is from 2 to 10 minims (0.10–0.6 Cc.).

OLEUM SESAMI.—Oil of Sesame.

Benne oil, Gingili oil, Teel oil, E.; *Huile de sésame,* Fr.; *Sesamöl,* G.; *Aceite de ajonjoli,* Sp.

The fixed oil expressed from the seeds of *Sesamum indicum* (Fam. *Pedaliaceæ*).

Origin.—Benne is an annual herb which is indigenous to India, but is now not found in the wild state; it is largely cultivated in most tropical countries and in the warmer portions of the temperate zone. It grows from 0.6 to 1.5 M. (2–5 Ft.) high, and has an erect, branching, bluntly quadrangular, and hairy stem, alternate or sub-opposite leaves, and short-stalked axillary flowers, with large white bell-shaped 5-lobed and somewhat 2-lipped corollas. The fruit is capsular, 2-valved, 4-celled, quadrangular and linear-oblong in shape, and contains numerous seeds, which are small, flattened, oval or ovate, smooth and shining, vary in color between whitish, yellow, reddish brown, and blackish, have a sweetish oily taste, and contain a straight embryo with a short radicle and large plano-convex oily cotyledons.

Fig. 294.

Sesamum indicum L.: *a*, flowering branch; *b*, section of seed.

Sesamum.—*Ajonjolé, Alegnia,* Sp.—*Benne, Sesame leaves,* E.; *Feuilles de sésame,* Fr.; *Sesamblätter,* G.—The leaves are mostly employed in the fresh state. They are long-petiolate, ovate or lance-oblong in outline, narrowed or rounded or somewhat heart-shaped at the base, more or less pointed above, entire on the margin or irregularly toothed, and the lower ones frequently cut into 3-toothed lobes or distinct leaflets. The leaves are prominently veined on the lower surface, are smoothish or somewhat pubescent, and have a mucilaginous taste. Their principal constituent is mucilage, which is precipitated from its aqueous solution by alcohol.

Preparation.—Oil of benne is obtained by subjecting benne-seeds to pressure, the yield being from 47 to 56 per cent. of the weight of seeds. The cold-expressed oil is superior in quality.

Properties.—Benne oil has a yellowish or yellow color, usually of a deeper hue than expressed almond oil, is thinner at ordinary temperatures than most other fixed oils, is nearly inodorous, and has a bland and agreeable peculiar taste, and the specific gravity 0.919–0.923 at 15° C. (59° F.). At —3° C. (26.6° F.) it becomes thick, and congeals usually at about —5° C. (23° F.), while the oil extracted by solvents congeals at about 5° C. (41° F.), forming a yellowish-white mass; when heated to between 150° and 200° C. (302° and 392° F.) it is decolorized. At 300° C. (572° F.) it assumes a brown color and at 335° C. (635° F.) it commences to boil. It is a non-drying oil, and on exposure to air does not readily turn rancid. Concentrated sulphuric acid converts it into a brown-red gelatinous mass; nitric acid, specific gravity 1.18, colors it gradually orange yellow, and when of greater strength, red; with a mixture of nitric and sulphuric acids it is transiently colored green, afterward red and brown red; in contact with nitrous acid it becomes reddish and brown red, and gradually forms a semi-solid mass.

The iodine value of benne oil varies from 103 to 112; its saponification value from 187.6 to 193. The most characteristic reaction for oil of sesame is the crimson color

developed on shaking the oil with sugar and hydrochloric acid, and generally known as the *Baudouin* test. In place of sugar, furfurol may be substituted, and according to F. Breinl (*Chem. Zeit.*, 1899, pp. 23, 647) 3 per cent. alcoholic solutions of vanillin, hydroxybenzaldehyde, or piperonal give equally good results. The Baudouin test is usually applied by dissolving 0.1 Gm. of cane-sugar in 10 Cc. of hydrochloric acid (specific gravity 1.19) in a test-tube, adding 20 Cc. of the oil to be tested, and thoroughly shaking the mixture. If the oil contains oil of sesame, the aqueous layer on separation will show a crimson color immediately or within a minute. The furfurol test is a modification of the Baudouin test, and applied as follows: In a test-tube mix 0.1 Cc. of a 2 per cent. alcoholic solution of furforol with 10 Cc. of the oil and 10 Cc. of hydrochloric acid, specific gravity 1.19 (P. Soltsien recommends acid of 1.125 specific gravity to minimize the danger of developing the red color with furfurol and hydrochloric acid alone), thoroughly shake the mixture, and allow it to separate. The aqueous layer will show an immediate crimson color if the oil contained 1 per cent. of oil of sesame. Purified furfurol should be used and the reagents separately tested to avoid error. Sesame oil heated on a water-bath with stannous chloride gives a permanent red color, which is not discharged on moderate dilution with water (distinction from turmeric) (P. Soltsien, *J. C. S.*, 1899, ii., p. 71). A permanent bluish-black color is developed on shaking equal volumes of sesame oil and the reagent composed of a mixture of 100 Cc. sulphuric acid, 50 Cc. of water, and 10 Cc. of 40 per cent. formaldehyde solution (J. Bellier, 1899). If sesame oil be shaken with an equal volume of concentrated hydrochloric acid, the latter will assume an emerald-green color, especially if the oil has been exposed for some time to the action of air and light (Bishop's reaction).

Composition.—Sesame oil consists of about 75 per cent. of the triglycerides of oleic (principally) and linolic acids, with 20 to 25 per cent. of myristin, palmitin, and stearin. The substance giving the Baudouin reaction is separable by means of animal charcoal, from which it may be recovered by extraction with ether, which upon evaporation leaves a reddish-brown resinous substance capable of giving the Baudouin reaction in a dilution of 1 : 500,000 (Bömer and Winter, *Zeit. Unters. Nahr. u. Genussm.*, ii., pp. 705–709). A crystallizable body having the composition $C_{11}H_{12}O_3$ and to which the name *sesamin* has been given, is a constant constituent of sesame oil, the oil containing from 0.2 to 0.5 per cent. Sesamin is obtainable in the form of colorless crystalline needles. It melts at 120° to 122° C. (248°–251.6° F.), is strongly dextrorotatory, readily soluble in chloroform, and with a mixture of equal parts of glacial acetic acid and sulphuric acid produces a brownish-green changing to cherry-red or reddish-blue coloration. Upon adding sulphuric acid to a chloroform solution of sesamin the acid layer becomes colored cherry red or blue. Sulphuric acid produces a violet coloration with an alcoholic solution of sesamin (Bömer and Winter, *loc. cit.*).

In 1901 (fiscal year) the importations of sesame oil into the United States amounted to 626,189 gallons, valued at $48,637, and in 1902, 707,760 gallons, valued at $57,359.

Action and Uses.—This oil was formerly employed as a food in pulmonary tuberculosis, but it is probably of less value than those which are more easily assimilated; for example, codliver oil and olive oil. Its local uses are practically the same as those of olive oil.

Allied Oils.—The name *German sesame oil* is sometimes applied to the slowly drying bland or slightly pungent oil expressed from the seed of *Camelina sativa* Crantz (*Myagrum sativum* L.).—Fam. *Cruciferæ*; *Wild* or *false flax*, *Camline*, E.; *Leindotter*, G. The seeds are known as dodder-seed and Siberian oil-seed.

Behen Oil or Ben Oil is expressed from the seeds of *Moringa aptera* Gærtn. (*M. Arabica* Pers.).—Fam. *Moringaceæ*. The yield is about 30 per cent. of a yellowish, inodorous, bland oil, which retains its neutral reaction for a long time, and is for that reason used in the East as a cosmetic and lubricant. These seeds are said to yield the true ben oil, while a bitter ben oil is obtained from the seeds of *Moringa pterygosperma* Gærtn. (*M. oleifera* Lam.; *Guilandina Moringa* L.), the horseradish tree of the East Indies.

Groundnut Oil or Peanut Oil.—This oil is obtained by expression from the well-known seeds of *Arachis hypogæa* L.—Fam. *Leguminosæ*, an annual herb indigenous to tropical America and now cultivated throughout the tropics. The peanut contains 9 per cent. of water, 26 of protein, 39 to 49 of fat, 24 of carbohydrates, and 2 of inorganic matter. The oil is pale yellow, thin, has a specific gravity of 0.9167–0.920, a peculiar nutty flavor, becomes turbid at about 3° C. (37.4° F.), and congeals near —5° C. (23° F.). It consists of the glycerides of oleic, linolic, arachic, and lignoceric acids, and has an iodine value of

85.6–101.3. Nitric acid colors the oil reddish, and sulphuric acid grayish yellow, then greenish brown; nitrous acid causes it to congeal to a whitish mass. In India groundnut oil is largely used under the name *katchung oil*, in place of olive oil.

KURUNG OIL, also known as *Kurunj* or *Poona Oil*. Obtained from the seeds of *Galedupa Pongam* Raeusch (*G. Indica* Lam.; *Pongamia glabra* Vent.; *Dalbergia arborea* Roxb.).—Fam. *Leguminosæ*, an East Indian tree, the odorous root and leaves of which are also used medicinally in that country. The oil is a thickish yellow liquid having the specific gravity 0.945 and becoming turbid at 7° C. (44.5° F.).

OLEUM SINAPIS VOLATILE, *U. S., Br.*—Volatile Oil of Mustard.

Oleum sinapis, P. G.; *Ol. sinapis æthereum.—Oil of mustard*, E.; *Essence de moutarde*, Fr.; *Senföl, Aetherisches Senföl*, G.

A volatile oil obtained from black mustard (freed from its fatty oil) by maceration with water and subsequent distillation, yielding, when assayed by the process given below, not less than 92 per cent. of allyl isothiocyanate.

The designation "black mustard" applies also to *Brassica juncea* Hooker fil. et Thomson. The seed which is used in the manufacture of the oil is obtained either from *B. nigra*, which is cultivated in Holland, Apulica, or the Levant, or more frequently from *B. juncea*, which is cultivated on a large scale in Sarepta, Russia, also in East India.

Volatile oil of mustard is not contained as such in the seeds, but is formed by ferment action. The ground mustard seed is deprived of its fatty oil with the aid of hydraulic presses. The press-cakes are mixed with tepid water, allowed to undergo fermentation, and then distilled with water vapor. The yield varies between 0.5 and 0.75 per cent. of the original seed. At a temperature exceeding 70° C. (158° F.) no fermentation takes place, because the myrosin is coagulated and rendered inactive.

The fermentation is brought about by the albuminoid ferment, myrosin, which acts on the glucoside sinigrin in the presence of water, with the formation of mustard oil, dextrose, and potassium acid sulphate: $C_{10}H_{16}NS_2KO_9$ (sinigrin) + H_2O (water) = $CSNC_3H_5$ (volatile oil of mustard) + $C_6H_{12}O_6$ (dextrose) + $KHSO_4$ (potassium acid sulphate). Beside this reaction others take place resulting in the formation of allyl cyanide and carbon disulphide, which are never entirely wanting in the oil. Contact with the copper of the still, or prolonged contact with water causes the separation of sulphur and the formation of allyl cyanide: $C_3H_5NCS + Cu = C_3H_5CN + CuS$. When the distillation has been conducted in a careless manner, the amount of allyl cyanide can be so large that the oil becomes lighter than water.

Properties.—Oil of mustard is a colorless or yellowish, limpid, and strongly refractive liquid with an exceedingly pungent and acrid odor. Inasmuch as it draws blisters when in contact with the skin, it should not be tasted. The specific gravity varies in accordance with the method of preparation between 1.016 and 1.030. The pharmacopœial requirements are 1.013–1.020 at 25° C. (77° F.), U. S., 1.018–1.025, P. G., and 1.018–1.030, Br. It should be soluble in alcohol in all proportions. Boiling-point 148° to 152° C. (298.4°–305.6° F.). With ammonia it forms thiosinamine. If to 3 Gm. of the oil 6 Gm. of sulphuric acid be gradually added, the liquid being kept cool, the mixture upon subsequent agitation will evolve sulphur dioxide, but will remain of a light yellow color; and although at first clear, it afterward becomes thick and occasionally crystalline, and the pungent odor of the oil disappears.

Composition.—In addition to "mustard oil," $CSNC_3H_5$, or allyl isosulphocyanate, the oil from black mustard contains variable amounts of allyl cyanide, C_3H_5CN, and carbon disulphide, CS_2. Possibly traces of the isomeric allyl thiocyanate and higher boiling (polymeric?) unknown compounds are present.

Adulterations and Tests.—Besides alcohol, carbon disulphide, castor oil, petroleum, etc., which are reported as being used as adulterants, artificial allyl isosulphocyanate may be found. When perfectly pure, it no doubt defies detection. "If a portion of the oil be heated in a flask connected with a well-cooled condenser, it should distil completely from 148° to 152° C. (298.4°–305.6° F.), and both the first and the last portion of the distillate should have the same specific gravity as the original oil (absence of alcohol, chloroform, petroleum, fatty oils, or more than traces of carbon disulphide). If a small portion of the oil be diluted with 5 times its volume of alcohol, and a drop of ferric chloride test-solution be added, no blue or violet color should be produced (absence of phenols)."—U. S.

Since mustard oil is to consist almost exclusively of one substance, its boiling-point is of importance. The fractions, if any, should distil within very limited range, and should have practically the same specific gravity.

Inasmuch as allyl isosulphocyanate combines quantitatively with ammonia to form thiosinamine, this has been used for assay purposes. However, carbon disulphide likewise combines with ammonia, forming ammonium sulphocyanate and ammonium sulphide, which are weighed with the thiosinamine.

Assay of Volatile Oil of Mustard.—Weigh accurately about 2 Gm. of volatile oil of mustard, and dilute this with sufficient alcohol to make 50 Cc. of the solution represent 1 Gm. of the oil; of this solution 5 Cc. are transferred to a 100-Cc. measuring flask, and 30 Cc. of tenth-normal silver nitrate solution and 5 Cc. of ammonia-water are added. The flask is well stoppered and set aside in a dark place for 24 hours. The contents of the flask are diluted with water to the 100 Cc. mark and filtered. To 50 Cc. of the filtrate 4 Cc. of nitric acid and a few drops of ferric ammonium sulphate test-solution are added, and finally sufficient tenth-normal potassium sulphocyanate solution to produce a permanent red color; not more than 5.6 Cc. of the latter reagent should be required (each Cc. of tenth-normal silver nitrate solution consumed corresponding to 0.00492 Gm. of allyl isothiocyanate).—U. S.

Action and Uses.—Volatile oil of mustard is rarely given internally. Locally it may be employed as a counter-irritant. Diluted with olive oil, it may be used as a substitute for mustard papers and as a stimulating liniment.

OLEUM SUCCINI.—Oil of Amber.

Huile volatile de succin, Fr.; *Bernsteinöl*, G.

A volatile oil obtained by the destructive distillation of amber, and purified by rectification.

Origin.—*Succinum, Ambra flava.—Amber*, E.; *Succin, Ambre jaune*, Fr.; *Bernstein, Agtstein*, G.—This fossil resin is the exudation from a number of extinct coniferous trees of the sub-orders *Abietæ* and *Cupressæ*, the principal source of the Baltic amber being *Pinites succinifer* Goeppert (*Pityoxylon succiniferum*), Kraus. It is principally obtained on the southern and southeastern coast of the Baltic, where it is cast ashore or dug out of beds. It has also been found in the interior of Europe and in Siberia, Greenland, and North America. It is hard, somewhat brittle, whitish, yellow, or red brown, transparent, translucent, or opaque, breaks with a conchoidal fracture, and frequently encloses vegetable fragments and insects. It is fragrant when heated, melts at about 287.5° C. (550° F.), dissolves in chloroform, but is insoluble in water, and only partly soluble in alcohol, ether, and volatile oils. Its density varies between 1.05 and 1.10. The annual production of amber in Prussia is estimated at 100,000 kilos (about 220,000 pounds).

Preparation.—The oil is obtained by the dry distillation of amber, succinic acid being formed at the same time. The crude oil thus collected is mixed with 6 times its volume of water, and distilled as long as oil is found in the distillate. The yield is usually stated to be from 60 to 70 per cent. of the crude oil; but Ebert (1865), who prepared the crude oil, obtained from 29 troy ounces of amber 21 fluidounces of oil, specific gravity 0.985, and on rectifying this with water only 2½ fluidounces, or about 12 per cent., of rectified oil, specific gravity 0.903, while the density of the residue had increased to 1.019.

Properties.—Crude oil of amber is a thick brown liquid of a strong empyreumatic and fetid odor, and variable specific gravity approaching the density of water; Power found it to be 0.975.

Rectified oil of amber is thin, colorless or yellowish, becomes darker and thicker on exposure, has a specific gravity of about 0.915, but varies in density and in the boiling-point. It has a pungent, empyreumatic, and somewhat balsamic odor, which is more pleasant than that of the crude oil, and a warm, acrid taste. It has a neutral or faint acid reaction, dissolves, according to Ebert, in 4 parts of alcohol specific gravity 0.817, and in 17 parts of alcohol specific gravity 0.835. It is readily soluble in ether, fixed and volatile oils, dissolves iodine, and, when heated, sulphur and caoutchouc. It absorbs some hydrochloric acid gas without forming a crystalline compound, and in contact with cold fuming nitric acid acquires a red afterward dark red-brown color, and is converted into a brown resinous mass having a peculiar musk-like odor, and formerly known under the name of *artificial musk*.

Composition.—In its purest state oil of amber is a mixture of hydrocarbons with some phenols.

Adulterations.—Oil of amber is not infrequently adulterated with oil of turpentine and with coal oil; the former is recognized by the brisk reaction with iodine, and by the formation of terpin when left in contact with alcohol and nitric acid; the latter by the decreased solubility in alcohol.

Action and Uses.—Oil of amber is an excellent counterirritant when locally applied to the skin. When given internally, it promotes all of the secretions, especially that of the kidneys, and acts as a stimulant and antispasmodic. It has been locally employed in the treatment of rheumatic joints, acute laryngitis, infantile bronchitis, and the convulsive seizures of children. When taken internally, it is said to be a valuable remedy for hysteria, whooping-cough, hiccough, amenorrhœa, and eruptive fevers attended with severe nervous phenomena. The internal dose is from 2 to 6 minims (0.10–0.40 Cc.). As an external application it should be diluted with 3 parts of olive oil.

OLEUM TEREBINTHINÆ, *U. S., Br., P. G.*—Oil of Turpentine.

Essence de térébenthine, Fr.; *Terpentinöl*, G.; *Essencia de treventina*, Sp.

A volatile oil distilled with steam from Turpentine.

(For an account of turpentine-yielding trees, see TEREBINTHINA.)

This great variety would indicate that the authors of pharmacopœias regard the oil from any one species about as good as any other. Like the U. S. P., the Br. P. admits other species than the one mentioned. While the Belgian, Russian, and Swedish pharmacopœias give preference to *Pinus maritima*, they admit oils from other species.

The principal species yielding oil of turpentine in the United States are *Pinus palustris* Mill. (*P. australis* Mich.), long-leaved or Southern pitch pine; *P. Taèda* L., loblolly or rosemary pine; *P. heterophylla* Ell. (*P. cubensis* Griesb.), Cuban, swamp or slash pine; *P. echinata* Mill. (*P. mitis* Mich.), short-leaved, yellow pine. With the extinction of the older turpentine orchards and the movement of this industry to the extreme South, there has also been a shifting of species. No distinction with reference to species appears at all to be made in the market.

By steam distillation the natural oleoresin is resolved into oil of turpentine and resin or rosin (see RESINA).

Composition.—Oil of turpentine consists almost wholly of the hydrocarbon pinene, $C_{10}H_{16}$, the American oil containing both dextrorotatory and lævorotatory varieties, whereas the French oil always shows lævorotation. Derivatives of pinene have also been met with, and camphene and fenchene are said to be present in many oils.

Properties.—Oil of turpentine should be a thin colorless liquid, possessing the peculiar terebinthinate odor and a sharp, acrid taste. It suffers by exposure to air and light, but a moist oil appears to keep better than one that has been carefully dried. While a dried oil readily thickens, a moist oil is apt to remain colorless and thin even when exposed to light, crystals of pinol hydrate separating out in the course of time. While the Br. P. mentions no specific gravity requirements at all, the P. G. restricts the limits to 0.865–0.875. The U. S. P. allows from 0.860–0.870 at 25° C. (77° F.). According to the U. S. P. and P. G., the larger part of the oil should distil between 155° and 162° C. (311° and 323.6° F.); according to the Br. P., between 160° and 180° C. (320° and 356° F.). Soluble in 3 times its volume of alcohol.

Adulterations and Tests.—Inasmuch as turpentine oil is the cheapest volatile oil, it has been used extensively as adulterant of other volatile oils, but is not adulterated by them. It is, however, adulterated with tar oils and with petroleum fractions. Tar oils, even when rectified, are apt to color a 5 per cent. caustic soda solution yellowish brown or dark brown, whereas turpentine oils color the solution but faintly yellowish. As a test for petroleum the P. G. demands solubility in 12 parts of alcohol. A less convenient method consists in destroying the pinene with nitric and sulphuric acids, and isolating the petroleum by steam distillation. "If 5 Cc. of oil of turpentine be shaken with an equal volume of potassium hydroxide test-solution, its color should not become darker than a light straw yellow upon standing 24 hours. If 1 Cc. of the oil be evaporated in a small dish on a water-bath, it should leave not more than a very slight residue (absence of petroleum, paraffin oils, or rosin). 3 drops of oil of turpentine, placed on a sheet of clean white filter-paper and exposed to the air, should evaporate entirely without leaving a permanent stain (absence of kerosene or rosin oil). If

5 Cc. of oil of turpentine be placed in a small beaker and 20 Cc. of sulphuric acid be gradually added, with agitation, while the beaker is cooled by immersion in cold water, and the contents, after cooling and renewed agitation, be transferred to a burette, graduated into tenths, the clear layer above the dark mass should not measure more than 0.35 Cc. (absence of petroleum benzin, kerosene, or similar hydrocarbons)."—U. S

Action and Uses.—When taken internally in small doses oil of turpentine produces a sense of warmth in the epigastrium, soon followed by a feeling of exhilaration. The pulse is quickened and respiration deepened. It is rapidly absorbed and escapes from the body through the lungs and kidneys, imparting the odor of violets to the urine, but not to the breath. On the circulation it acts as a mild and fleeting stimulant to the vasomotor centre, in small amounts produces acceleration of the pulse, and in larger quantity slows the pulse by stimulation of the pneumogastric nerves.

Moderate medicinal doses increase the activity of the kidneys. Somewhat larger quantities are apt to give rise to aching in the loins, frequent micturition, and scalding urine. By toxic doses there are induced intense burning in the epigastric region, great thirst, muscular relaxation, impairment of sensation, at first exhilaration of the mind, followed finally by unconsciousness. The pulse becomes feeble and rapid, the pupils dilated, and the face cyanotic. Nausea and vomiting occur in some cases. Those organs by which the drug is eliminated suffer from extreme irritation, that of the genito-urinary tract manifesting itself in scanty and bloody urine and violent strangury. Death from overdoses of turpentine is rare. The majority of fatal cases reported have been in children. The lethal dose is not definitely known, 4 to 6 ounces (120–180 Cc.) having failed to destroy life in adults.

Inhalation of the vapor produces irritation of the respiratory tract, and occasionally frontal headache and renal inflammation. Its application to the skin results in reddening, and if allowed to remain too long, vesication and severe ulceration are apt to occur.

Absorption from the skin is quite rapid, and may be sufficient in quantity to severely irritate the kidneys. Turpentine is given internally as a diffusible stimulant of especial value in exhausting fevers. It is indicated particularly if ulceration of the intestine exists or if the abdomen is tympanitic. In those cases of typhoid fever which, toward the end of the second week, present a dry, red, fissured tongue and marked tympanites, with profound depression, the administration of from 5 to 10 minims (0.30–0.60 Cc.) of turpentine every 2 to 4 hours is followed by the happiest results. Again, in the convalescence from typhoid fever, if diarrhœa persists and relapses recur, an evidence that the ulceration of Peyer's patches has not completely healed, turpentine is a sovereign remedy, in fact by some is considered a specific.

In addition to its administration by the mouth for the meteorism of typhoid fever, it may be employed in enemata or in stupes applied to the abdomen. In passive hemorrhages from the stomach, intestine, lung, and uterus, turpentine enjoys perhaps too great a reputation as a hemostatic, but may be employed at times with benefit. It has been found of some value in the treatment of purpura hemorrhagica. In chronic inflammations of the genito-urinary tract, as pyelitis, cystitis, and urethritis, turpentine is a useful remedy. Its influence as a stimulating diuretic may be of advantage in well-advanced nephritis, but it is contra-indicated if any acute irritation of the kidney exists. In incontinence of urine from lowered tone of the bladder muscles, and in sexual impotence and spermatorrhœa, the drug may give relief. Although an efficient remedy to be given for the removal of the tapeworm, so large a dose, ½ to 1 ounce (16–30 Cc.), is necessary that enough of the drug may be absorbed to produce severe renal irritation. Externally turpentine is used as a counterirritant to relieve the pain and influence the progress of deep-seated inflammations. For this purpose it is applied over a large area in the form of a stupe, which should remain in position until the skin is distinctly reddened. When a milder action is desired, as in the treatment of lumbago, chronic rheumatism, bronchitis, etc., the oil of turpentine should be diluted with olive oil or the official liniment should be employed. Enemata containing from 2 to 4 drachms of turpentine to the pint of soap solution or emulsion of asafœtida are very valuable in tympanites. The usual dose of turpentine is from 5 to 20 minims (0.30–1.30 Cc.), repeated every 2 to 6 hours. It may be administered in capsules or on a piece of sugar. The official emulsion in the dose of from 1 to 4 drachms (4–16 Cc.) presents an efficient preparation, and may be made more agreeable by the addition of a small quantity of oil of gaultheria or cinnamon.

OLEUM TEREBINTHINÆ RECTIFICATUM, *U. S., P. G.*—Rectified Oil of Turpentine.

Essence de térébinthine purifiée, Fr.; *Gereinigtes Terpentinöl*, G.

Preparation.—Oil of turpentine, a convenient quantity; solution of sodium hydroxide, a sufficient quantity. Shake the oil of turpentine thoroughly with an equal volume of solution of sodium hydroxide, and introduce the mixture into a copper still connected with a well-cooled condenser. Recover about three-fourths of the oil by distillation, separate the clear oil from the water, and filter. Keep the product in well-stoppered amber-colored bottles in a cool place.—U. S.

The directions of the German Pharmacopœia are identical with the above, except that the oil is shaken with 6 times its volume of lime-water instead of an equal volume of the sodium hydroxide solution.

Properties and Tests.—Rectified oil of turpentine is a thin colorless liquid, having the general properties mentioned under OLEUM TEREBINTHINÆ. Its specific gravity is slightly lower than that of the ordinary oil, ranging from 0.860–0.865 at 25° C. (77° F.). If about 10 Cc. of the oil be evaporated in a capsule on a water-bath, no weighable residue should be left.—U. S. An alcoholic solution of the oil should not change the color of moistened litmus-paper.

The object of rectifying the commercial oil of turpentine is to remove any resinified products present.

Only the rectified oil should be used whenever oil of turpentine is intended for internal use.

Action and Uses.—See OLEUM TEREBINTHINÆ.

OLEUM THEOBROMATIS, *U. S., Br.*—Oil of Theobroma.

Oleum theobromæ; Oleum concretum e semine theobromæ cacao, Fr. Cod.; *Oleum cacao*, P. G.—*Butter of cacao*, E.; *Beurre de cacao*, Fr.; *Kakaobutter*, G.; *Manteca* (*Aceite*) *de cacao*, Sp.

A fixed oil expressed from the roasted seeds of *Theobroma Cacao* L. (Fam. *Sterculiaceæ*).

Preparation.—In the manufacture of chocolate a portion of the cacao-seeds are deprived of their fat by removing the shells, heating the kernels to about 70° C. (158° F.), and pressing them between hot iron plates. The expressed fat is usually run into rectangular molds and allowed to congeal. The yield from the different varieties of cacao is from 35 to 45 per cent.

Properties.—Cacao butter is a yellowish-white fat, gradually turning white by age. It is sufficiently hard at ordinary temperatures to be broken into smaller pieces, but softens by the warmth of the hand and melts when taken into the mouth. It has an agreeable odor and a bland chocolate-like taste, dissolves in ether, acetic ether, and 100 parts of cold and in 20 parts of boiling absolute alcohol, separating again from the latter solution on cooling, with the exception of a small portion which remains dissolved. Its specific gravity is 0.970–0.976 at 25° C. (77° F.).—U. S. It is brittle at 15° C. (59° F.), and melts between 30° and 35° C. (86° and 95° F.), U. S., P. G.; 31.1° to 33.9° C. (88°–93° F.), Br.; forming a pale-yellow, transparent liquid which congeals at 20.5° C. (69° F.), the temperature rising to about 26.5° C. (79.7° F.). The specific gravity and fusing-point are variable, according to the length of time the melted fat has congealed.

Composition.—Cacao butter consists of the glycerides of stearic (about 40 per cent.), palmitic, lauric, and small quantities of the glycerides of butyric, formic, acetic, linolic, and arachidic acids.

Tests.—When mixed with other solid fats the fusing-point and specific gravity do not afford reliable tests for determining such admixtures. The presence of tallow may be detected by burning the oil with a wick for a short time, and then extinguishing the flame, when a peculiar tallow-like odor will be observed. For the detection of adulterations Björkland (1864) proposed the test incorporated into the Pharmacopœia, as follows: "If 1 Gm. of oil of theobroma be dissolved in 3 Cc. of ether, in a test-tube at a temperature of 17° C. (62.6° F.), and the tube frequently plunged into water at 0° C. (32° F.), the liquid should not become turbid nor deposit a granular mass in less than 3 minutes; and if the mixture, after congealing, be exposed to a temperature of 15° C. (59° F.), it should gradually form a perfectly clear liquid (absence of wax,

stearin, tallow, etc.)."—U. S. If pure, cacao butter will separate granules in not less than 3 minutes; if adulterated with tallow or suet, a turbidity will appear at once or within 2½ minutes, according to the quantity of the adulterant, of which 5 per cent. may thus be detected. When the congealed mixture is exposed to a temperature of about 15° C. (59° F.) it will gradually become clear again if the cacao butter was pure, but not if it was adulterated. According to Lamhofer, petroleum benzin may be substituted for the ether with nearly identical results, except that the pure oil separates rather more slowly and is always granular, while other fats render the entire liquid cloudy. "The solution of 1 part of oil of theobroma in 2 parts of ether should remain clear if kept for a day at a temperature of 12° to 15° C. (53.6°–59° F.)."—P. G. Oil of theobroma, saponified by alcoholic potassium hydroxide test-solution, should show a saponification value of 188 to 195. If 0.8 Gm. of oil of theobroma be dissolved in 10 Cc. of chloroform in a 250-Cc. bottle or flask, and 25 Cc. of a mixture of equal parts of alcoholic iodine test-solution and alcoholic mercuric chloride test-solution added, and if, after standing for 4 hours, protected from light, 20 Cc. of potassium iodide test-solution be added, and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate solution an iodine figure of not less than 33 nor more than 38 should be obtained.—U. S.

During the fiscal year 1901 there were imported into the United States 2,984,996 pounds of cacao butter valued at $790,748, and in 1902, 3,548,041 pounds valued at $782,815.

Action and Uses.—Cacao butter is extensively employed as a base for suppositories. It is one of the few excipients which can be used in pills containing substances that readily decompose, as silver nitrate and potassium permanganate. Locally it is emollient. It has been given internally as a food in wasting diseases.

Allied Fats.—More or less odorous fats are expressed from the seeds of several species of *Bassia*.—Fam. *Sapotaceæ*. *Bassia longifolia* L. yields the greenish *elloopa* or *elloopa oil*. *Bassia butyracea* Roxb. gives the tallow-like *fulwa butter*. The *mahwah butter* melts at about 45° C. (113° F.), is greenish or yellowish, and comes from *Bassia latifolia* Roxb. These fats come from India. The *shea butter*, *galam butter*, or *bambuk butter* is obtained from *Bassia* (*Butyrospermum* Kotschy) *Parkii*, DC., of tropical Africa. It is pale greenish or grayish, has a cacao-like odor and mild taste, and melts at about 28° C. (82.4° F.). The fleshy mahwah-flowers are used as food and for distilling a spirit; when dry they are said to contain 50 per cent. of sugar.

Mafura Tallow has also a cacao-like odor and a mild taste, but it is of a yellowish color and melts at 42° C. (107.6° F.). It is obtained by boiling the seeds of *Trichilia emetica* Vahl *s. Mafureira oleifera* Bertero (Fam. *Meliaceæ*), of tropical East Africa.

OLEUM THYMI, *U. S., P. G.*—Oil of Thyme.

Essence de thym, Fr.; *Thymianöl*, G.

A volatile oil distilled from the leaves and flowering tops of *Thymus vulgaris* L. (Fam. *Labiatæ*), and containing, when assayed by the process given below, not less than 20 per cent., by volume, of phenols.—U. S. Thyme grows abundantly in the wild state in the mountains of southern France. Small amounts of oil have also been obtained from the cultivated herb, but these oils are of little commercial importance. The botanical source of the Spanish oil is not definitely known.

Properties.—The crude oil of thyme is of a dark reddish-brown color. This color has been attributed quite generally to compounds of phenol with iron, with which the oil was supposed to have come in contact during the process of distillation. This color disappears on heating, and reappears in the distillate upon standing. This would indicate that the pigment is of a quinhydrone character, such as has been found in Monarda oils. Commercially "red" and "white" oil are distinguished. The latter, however, is not obtained by simple rectification of the ordinary kind. "White" thyme oil offered at a lower price than "red" oil is apt to contain much turpentine oil.

The U. S. P. describes oil of thyme as a colorless liquid having a strong odor of thyme, and an aromatic, pungent, afterward cooling taste.

The specific gravity of an oil should be above 0.900 (P. G.), varying for good oils between 0.905–0.920; the U. S. P. requirement is 0.900–0.930 at 25° C. (77° F.). The oil is slightly lævogyrate, the U. S. P. allowing not more than —3° in a 100-Mm. tube, but usually too dark to admit of the determination of this constant. It is soluble

in ½ part of 90 per cent., and in 1 to 2 parts of 80 per cent. alcohol; of 70 per cent. alcohol 15–30 parts are mostly requisite to form a clear solution.

Composition.—The phenol content of the oil varies, as a rule, between 20 and 25 per cent., and in rare instances rises to 42 per cent. The phenol of the French and German oil is mostly thymol; sometimes, however, carvacrol or a mixture of both. The phenol of the Spanish oil is carvacrol, and the phenol content as high as 50–70 per cent. Besides these phenols, oil of thyme contains cymene, *l*-pinene in very small amount, borneol, and linalool.

Adulterations and Tests.—As already stated, turpentine oil is frequently added. This lowers the specific gravity and increases the angle of rotation. The addition of the wild thyme oil does not change the specific gravity, but increases the angle of rotation, its α_D being as high as —12° and more. The thymol assay, however, is the most important criterion.

If 1 Cc. of oil of thyme be shaken with 10 Cc. of hot water and, after cooling, the liquid be passed through a wet filter, the filtrate should not assume, with a drop of ferric chloride test-solution, a bluish or violet color (absence of official phenol).

Assay of Oil of Thyme.—Introduce 20 Cc. of solution of sodium hydroxide (1 in 20) into a burette of 50-Cc. capacity (graduated in $\frac{1}{10}$ Cc.). Add 10 Cc. of the oil to be assayed, stopper the burette with a well-fitting cork, shake the mixture thoroughly, and set aside for 12 to 24 hours. Drops of oil adhering to the side of the burette should be loosened by tapping and rotating it. After the alkaline solution has become clear, the volume of non-phenol oil remaining (which should measure not more than 8 Cc.) is noted and subtracted from the 10 Cc. of the oil originally taken. The difference, multiplied by 10, indicates the percentage of phenols in the oil.—U. S.

In order to determine at the same time whether the oil contains thymol or carvacrol, the alkaline solution of phenylate is separated from the oil, transferred to a separating funnel, and acidulated with sulphuric acid. After the phenol has completely separated, the aqueous solution is run off and the oil set aside in a capsule in a cool place. If the oil consists of thymol, it solidifies upon standing, or crystallization may be induced by adding a fragment of a thymol crystal. If it consists of carvacrol the oil remains liquid. If both phenols are present, it crystallizes partially.

This method yields approximate results only. On the one hand the alkaline solution of phenols dissolves some of the hydrocarbons, on the other hand a part of the phenol remains dissolved in the oil. Both errors probably compensate each other. To remove the hydrocarbons dissolved in the alkali by shaking with ether would simply increase the error, inasmuch as thymol and, still more, carvacrol can be partly extracted from their alkaline solutions by ether.

More rational, though more complicated, is the assay method devised by Kremers and Schreiner. It is a modification of the method suggested by Messinger and Vortmann, and is based upon the fact that in alkaline solution thymol combines with iodine to a red insoluble compound, and that the excess of iodine can be titrated back by standard thiosulphate after the solution has been acidified. Each molecule of thymol requires 4 atoms of iodine for precipitation. The process is carried out in the following manner:

5 Cc. of the oil to be examined are weighed and transferred to a burette provided with a glass stopper and calibrated into tenths. The oil is diluted with about an equal volume of petroleum ether. 5 per cent. sodium hydroxide solution is added and the two solutions shaken. After the two solutions have separated upon standing, the aqueous solution is drawn off into a 100-Cc. flask. This operation is repeated as long as the ethereal solution diminishes in volume. The alkaline phenol solution is diluted to 100 Cc., or, if necessary, to 200 Cc.

10 Cc. of this solution are transferred to a measuring flask of 500-Cc. capacity and $\frac{N}{10}$ iodine test-solution added in slight excess, whereby the thymol is precipitated as a dark-brown iodine compound. In order to ascertain whether sufficient iodine has been added, a few drops are transferred to a test-tube and acidulated with hydrochloric acid. An excess of iodine is indicated by a brown color of the solution, an insufficient amount of iodine by milkiness produced by thymol. An excess of iodine having been established, the entire alkaline solution is acidulated and diluted to 500 Cc. In 100 Cc. of the filtrate the excess of iodine is ascertained by titration with $\frac{N}{10}$ sodium thiosulphate solution.

The number of Cc. of sodium thiosulphate solution required are deducted from the

volume of iodine solution used, and the resultant multiplied by 5, this product indicating the total amount of iodine used by the thymol.

Each Cc. of $\frac{N}{10}$ iodine test-solution corresponds to 0.003741 Gm. of thymol. From the amount of thymol found in the alkaline solution the percentage of phenol in the original oil can readily be ascertained.

The reaction involved is expressed by the following equation: $C_{10}H_{14}O + 4I + 2NaOH = C_{10}H_{12}I_2O + 2NaI + 2H_2O$. The carvacrol assay should be slightly modified, because the carvacrol iodide separates in a milky state. In order to obtain a precipitate the mixture is thoroughly shaken after the addition of iodine, and then filtered. Then the solution is acidulated with hydrochloric acid, and the process continued as directed under thymol. The calculation is the same.

Action and Uses.—Garden thyme and wild thyme have long been used as condiments to promote digestion and to flavor insipid dishes. Externally it has been applied in fomentations, baths, fumigations, etc., to relieve muscular rheumatism and chronic gout, to cure scabies, indolent ulcers, etc.

In man, the daily dose of 5 or 6 drops acts as a general stimulant, and when the oil is continued in increasing doses it renders all the functions more active and energetic. The urine increases in quantity and acquires a violet odor. If the daily quantity be gradually augmented from 6 to 12 drops, the effects are apt to be intensified, and the odor of the medicine may be perceived on the breath and the skin. Sometimes the skin presents erythematous or papular eruptions and the fauces become dry.

Externally the oil is applied in baths and lotions (by mixing with water or alcohol a sufficient quantity of powdered sodium carbonate previously impregnated with the oil) to the treatment of scabies, muscular rheumatism, etc. Applied on cotton it mitigates the pain of toothache, earache, etc. The average dose is 2 minims (0.1 Cc.).

The essential oil is most conveniently given in capsules, owing to its acrid taste and the eructations it causes.

OLEUM TIGLII, *U. S.*—Croton Oil.

Oleum crotonis, Br., P. G.; *Huile de Croton Tiglium*, Fr. Cod.; *Krotonöl*, G.; *Aceite de grano tiglio*, Sp.

The fixed oil expressed from the seeds of *Croton Tiglium* L. (*T. officinale* Klotzsch —Fam. *Euphorbiaceæ*).

Origin.—Croton seeds or Molucca grains (*Semen vel Grana Tiglii; S. v. G. Crotonis.—Grains de Tilly, Grains de Moluques, Petits pignons d' Inde*, Fr.; *Granatill, Purgirkörner*, G.; *Grano Tiglio*, Sp.) are the product of a large shrub, native of the East Indies and cultivated in a number of tropical countries. The seeds are borne in a 3-celled capsule somewhat resembling that of the castor-oil plant, but with a single seed in a cell. The seeds have a form almost identical with that of the castor-oil seed, but average somewhat larger, have a less conspicuous caruncle, and a roughish not shining surface, of a brown color, or blackish where the outer layer has become abraded. The structure is identical with that of the castor-oil seed. There is little odor, and the oily taste soon becomes extremely acrid. The yield of oil is from 30 to 40 per cent. of the weight of the seeds, about one-third of the latter pertaining to the seed-coats. Several seeds have been used to substitute or adulterate Croton seeds, more in earlier times. All are larger, and either grayish black or dark grayish brown in color. The principal one is the East Indian *Kuli seed*, the product of *Croton oblongifolius* Roxb., of which the root-bark is an important drug in India. According to Lloyd (*Western Druggist*, 1898, p. 151), croton seeds figured as purgatives in European literature as early as 1578, under the name *pini nuclei moluccani*, and later as *grana teglia* or *grana Molucca*.

FIG. 295.

Croton seed: lateral and ventral view, and longitudinal section, showing embryo.

Preparation.—Croton oil is obtained in large quantities in India and in Great Britain by subjecting the seeds, freed from their integuments, to pressure, and also by extraction with volatile solvents.

Properties.—Croton oil from India is of a pale-yellow color; that made in England is of a more or less deep reddish-brown hue, the darker color being probably due to the greater age of the seed and to the higher temperature at which the oil is expressed. It is somewhat viscid and slightly fluorescent. It has a slight, peculiar, somewhat rancid

odor, and a taste which is at first mild, but afterward acrid and burning. Great caution is necessary in tasting the oil. When applied to the skin it produces rubefaction or a pustular eruption. Its reaction to test-paper is distinctly acid and its consistence rather viscid. It dissolves freely in ether, chloroform, carbon disulphide, petroleum ether, and fixed and volatile oils. When fresh it is soluble in from 55 to 60 parts of alcohol, the solubility increasing by age.—U. S. Alcohol dissolves from fresh croton oil about 20 per cent. of oil which carries the vesicating principle, the purgative principle remaining in the insoluble portion (H. Senier, 1883). The variations in the solubility in alcohol and other properties of croton oil are in part attributable to the age (Warrington, 1865) of the oil, and probably also to the different species of seeds used in its preparation. According to Dr. M. Burrough, much of the oil expressed in India is derived from Barbadoes nuts, *Jatropha Curcas*, or *Curcas purgans* (see below). Croton oil has the specific gravity at 25° C. (77° F.) of 0.935–0.950 (U. S.), congeals at —16° C. (3.2° F.), and is characterized by a high saponification value (212 to 218). Exposed to the air croton oil becomes more or less viscid, but is not a drying oil. It does not form elaidin.

Composition.—Croton oil is composed of the glycerides of stearic, palmitic, myristic, lauric, and oleic acid, and of the volatile acids, acetic, butyric, formic, valeric, and *tiglic* (Geuther and Frölich, 1870) *acid*, $C_5H_8O_2$. Tiglic acid is an isomeride of angelic acid, and identical with Frankland and Duppa's methyl-crotonic acid. It melts at 64.5° C. (148.1° F.) and boils at 198.5° C. (389.3° F.). The vesicant principle of croton oil was determined by Dunstan and Boole (*Proc. Roy. Soc.*, London, lxiii., 1895) to be *croton-resin*, $C_{13}H_{18}O_4$, a bright-yellow, hard, brittle substance, melting at 90° C. (194° F.), and which is insoluble in water and benzene, but readily soluble in alcohol, ether, and chloroform.

Tests.—Croton oil should be completely soluble in absolute alcohol, and the solution not redden litmus-paper (Br.). If to 2 Cc. of the oil 1 Cc. of fuming nitric acid and 1 Cc. of water be added, and the mixture be shaken vigorously, it should not solidify, either completely or partially, but only thicken slightly, after standing for 1 or 2 days (absence of other non-drying oils). If 0.3 Gm. of croton oil be dissolved in 10 Cc. of chloroform in a 250-Cc. bottle or flask, and 25 Cc. of a mixture of equal parts of alcoholic iodine test-solution and alcoholic mercuric chloride test-solution added, and if, after standing 4 hours, protected from the light, 20 Cc. of potassium iodide test-solution be added, and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate solution, an iodine figure of not less than 102 nor more than 105 should be obtained.—U. S. Croton oil may be identified in other oils by shaking the oil with a dilute alcoholic solution of potassium hydroxide, and after separation acidulating the alcoholic liquid with dilute hydrochloric acid and extracting with ether. The supernatant ether is removed, evaporated, and the residue applied upon the arm, when in a few hours redness and the peculiar pustular eruption will appear if the oil contained croton oil. When gently heated with twice its volume of absolute alcohol, it forms a clear solution, from which the oil should separate on cooling.—U. S.

In 1901 (fiscal year ending June 20) 461 pounds of croton oil, valued at $219, were imported into the United States, and in 1902, 1135 pounds, valued at $565.

Action and Uses.—In medicinal doses croton oil produces profuse watery evacuations in from 1 to 4 hours, accompanied by some tenesmus and a sense of heat in the anal region. In overdose it is a violent depressant poison, producing vomiting, profuse purging, severe griping, collapse, and death. The quantity necessary to cause a fatal result varies within wide limits. The minimum fatal dose is not known. Death has occurred in an infant of 12 months from 3 drops of the oil; on the other hand, there are reported cases in which recovery has resulted when as much as 1 drachm (4 Cc.) has been ingested. Applied to the skin, it may be absorbed and produce purgation, but, as a rule, its effects are local, and consist in a papular eruption which gradually becomes pustular, even in the absence of pyogenic bacteria. The minuteness of the dose of croton oil renders it useful when a more bulky purgative cannot be given, or when the patient struggles against the administration of a remedy. Such conditions are met with in the unconsciousness of apoplexy, in coma, in the cerebral congestion, and in the obstinate constipation sometimes met with in mania. Children do not bear the drug well. In obstinate constipation, complicating the various forms of paralysis, and in chronic lead-poisoning, croton oil is sometimes given with the happiest results when all other purgatives have failed.

As a counterirritant it is applied externally in sciatica and other nerve inflammations, chronic articular rheumatism, gout, and diseases of the lungs. When used externally it should usually be mixed with 2 or 3 parts of castor oil, olive oil, or soap liniment, and thoroughly rubbed into the skin with a piece of muslin or flannel. At times it is necessary to apply the oil undiluted.

The dose is from ½ to 2 minims (0.025–0.10 Cc.), in an emulsion, or diluted with a few drops of some bland oil. It may also be given in pill. It produces great irritation and inflammation. When poisoning occurs, oils, milk, mucilage, or gelatin solution should be given to allay the inflammation of the mucous membranes, and opium for the relief of the pain. If collapse supervenes, external heat should be applied and alcohol and strychnine administered as stimulants.

Allied Drugs.—CURCAS (*Semina ricini majoris, Semen Curcadis, Semen ficus infernalis, Nuces catharticæ Americanæ.—Purging-, Physic-,* or *Barbadoes nut,* E.; *Purgirnuss, Schwarze Brechnuss, Grosse Ricinuss,* G.; *Pignon des Barbades* or *d' Inde, Semence des médiciniare,* Fr.; *Piñon,* Sp.) is the seed of *Jatropha purgans* (Adans) (*Curcas p.* Adans.; *C. Adansonii* Endl.; *Jatropha Curcas* L.), a shrub or small tree of tropical America. The seeds, and the oil expressed from them, are largely used in their own home as a purgative, substituting Castor, or more particularly Croton Oil. They have also been rather largely introduced to Europe for the same purpose, especially in Spain and Portugal. The seed is 1.5 to 2 Cm. (⅗–⅘ In.) long, oval or a little broader near one end, moderately flattened dorsally, black or blackish gray, striate or somewhat ribbed, rough and not shiny, bearing a broad whitish hilum and caruncle at the smaller end. The kernel consists of an oily whitish albumin with a central embryo having the general structure of that of the Castor oil seed. The seeds are inodorous, of a sweetish and oily taste, later becoming acrid. They contain about 30 to 40 per cent. of a colorless or light-yellow fixed oil, of a specific gravity of 0.92, congealing to a butyraceous mass at —8° C. (17.6° F.); inodorous and nearly insoluble in alcohol. The acid present has been described as curcinoleic acid ($C_{15}H_{28}O_3$). That previously described as isocetic acid is now believed to be a mixture. With the oil exists a small amount of resin. As in Castor and Croton seeds, there also exists, probably chiefly in the embryo, a toxic albuminoid substance called curcin. This becomes inert at a temperature above 50° C. (122° F.) or when treated with precipitants (Siegel).

FIG. 296.

Curcas (Nat.).

The brown and somewhat smoother seeds of *Jatropha multifida* L. (*Curcas m.* Endl.) are similarly used, and their oil is believed to be identical. The seeds of *Joannesia princeps* Vell. (*Anda Brasiliensis* Raddi; *A. Gomesii* Juss.; *Andicus pentaphylla* Vell.), the *Anda Assu, Semen Andsu, Ararafrüchte,* or *Andanüsse,* of tropical America, act almost exactly the same, both as a medicine and as an emetico-cathartic poison. They are sub-reniform, and somewhat resemble chestnuts in color and general appearance, but possess a whitish aril.

The seeds of various species of *Euphorbia* (see EUPHORBIACEÆ) contain fixed oils which act more or less like Croton Oil. Two drops of that from the seeds of *E. calyculata* H. B. K., a Mexican species, are said to act as a drastic, and it has been proposed to use this under the name *Mexican Croton Oil.* It is yielded to the extent of 30 per cent., and is amber yellow, nearly odorless if fresh, bland at first, afterward acrid, soluble in ether and chloroform, partly in alcohol. The seeds of *E. Lathyris* L. (*Tithymalis L.* Scop.), the *Caper-spurge* or *-bush, Wild caper, Garden* or *Myrtle spurge, Gopher-* or *Mole-plant, Wolf's milk, Catapuce,* medicinally known as *Semina cataputiæ minoris, Semina lathyridis majoris, Grana regia majora, Kleine Springkörner, Kleine Purgirkörner,* of Europe, naturalized in the United States, yield about 40 per cent. of an oil much like Croton Oil; when fresh, colorless, odorless, and tasteless, but becoming acrid and correspondingly more violent in its action with age. Upon standing, it deposits a crystalline mass. If perfectly fresh, even so much as 10 drops act only mildly. This change in activity is in all probability due to the separation of the fatty acid. It is said to contain *æsculetin.* The seeds themselves are also purgative, but there is with this action a distinct tendency toward emesis. Five of these small seeds have purged.

OLIBANUM.—Frankincense.

Gummi resina olibanum, Thus.—Weihrauch, G.; *Oliban, Encens,* Fr.; *Incienso,* Sp.

A gum-resin obtained from *Boswellia Carterii* Birdw. and other species of *Boswellia* (Fam. *Burseraceæ*).

Origin.—The geographical source, methods of production and collection, and commerce of this drug are identical with those of Myrrh (see MYRRHA). The Olibanum plants are small trees or large shrubs with pinnate leaves. The Indian olibanum or Male incense is from *B. serrata* Roxb. (*B. thurifera* Colebr.), of India.

Description.—In separate, irregularly oblong or rounded, pebble-like tears, usually less than 1.25 Cm. (½ In.) in diameter, and rarely reaching double this size, varying from nearly white (when fresh) to more or less yellow or even reddish brown, rarely with a greenish-blue tinge, the surface more or less powdery; brittle, the fracture nearly flat, the surface waxy-lustrous; thin fragments somewhat translucent; odor balsamic and terebinthinate, softening between the teeth, and of an aromatic and resinous and somewhat bitter taste; odor, on burning, highly and pleasantly aromatic; forming a white emulsion with water and almost wholly soluble in alcohol.

The poorer grades of Olibanum may exhibit masses of softish, coherent tears, dark colored, opaque on fracture, or containing much impurity. "Seed-Olibanum" is in small, grain-like tears and usually with much sand or other earthy matter intermixed.

Constituents.—Olibanum consists of from 60 to 70 per cent., or occasionally more, of resin, 30 to 35 per cent. of gum, 3 to 8 per cent. of volatile oil, and a small amount of an unstudied bitter principle. The volatile oil is colorless to yellowish, has the odor of the drug with a slight lemon-like fragrance, and a specific gravity of 0.875–0.885. It consists chiefly of l-pinene ("olibene"), dipentene, and phellandrene (*Gildemeister and Hoffmann*). The resin is *Boswellic* or *Boswellinic acid* ($C_{32}H_{52}O_4$) and *Olibano resin*, $(C_{14}H_2O)_n$, in equal proportions, with a little ester of the former acid (*Halbey*). The gum is mostly arabin (see ACACIA), the remainder bassorin (see TRAGACANTHA).

Action and Uses.—This gum resin is rarely employed in internal medicine at the present time. Its principal use is in the preparation of extemporaneous plasters. Because of its stimulating properties it may be substituted for either BALSAM PERU or BALSAM TOLU (which see). It was formerly combined with soap as an excipient, and administered in pill form, in doses of from 15 to 30 grains (0.97–1.94 Cc.).

Allied Products.—The genus *Boswellia* is credited with some 10 species of northeastern Africa and India, but the species are difficult of definition and the number is probably very much greater. *B. Frereana* Birdw., of the same region with the Olibanum plant, is regarded as the source of the *African Elemi* or *Luban Mayeti*.

ONAGRACEÆ.—The Evening Primrose Family.

A family of 36 genera and nearly 500 species of highly ornamental flowering plants, including the Fuchsias, Epilobiums, Lopezias, and Œnotheras. From an economic standpoint the family is of little importance except for decorative purposes. Many of its herbs are rich in tannin, and have a considerable domestic and some professional use as astringents.

FIG. 297.

Evening Primrose (½ Nat.).

ŒNOTHERA (*Evening Primrose, Night willow-herb, Rampion, Scurvish*, E.; *Nachtkerze*, G.; *Onagre*, Fr.) is the root, and especially the leaves and flowering tops, of *Onagra biennis* (L.) Scop. (*Œnothera b.*—L.), a tall, stout herb growing throughout most of North America. The root is conical, 12 to 25 Mm. (½–1 In.) thick at the base, 10 to 15 Cm. (4–6 In.) long, with spreading branches, externally pale brown or sometimes reddish, with a thin bark, internally white, fleshy, inodorous, of a sweetish taste, and in the second year woody and tough. The *stem* is from 0.9 to 1.8 M. (3–6 Ft.) high, rough, hairy, often purplish. The *leaves* are alternate, ovate-oblong or oblong-lanceolate, 7 to 12 Cm. (3–5 In.) long, somewhat petiolate, acute, nearly entire, and short-hairy. The *flowers* are in terminal leafy spikes, have a sessile cylindrical ovary united with the long tubular calyx, 4 obcordate yellow petals, and 8 stamens, and produce a 4-valved capsule containing numerous seeds. The herb is inodorous and has a mucilaginous and mildly astringent taste. The constituents have received no careful investigation. Mucilage and tannin exist in considerable amount. Because of its antispasmodic properties this remedy has been employed internally in the treatment of whooping-cough, hiccough, and spasmodic asthma. In the form of a 25 per cent. ointment it may be locally used as a remedy for porrigo and other infantile cutaneous affections. The internal dose is from ½ to 1 fluidrachm (1.8–3.7 Cc.) of the fluidextract.

Onagra, with the very similar genera *Anogra* and *Œnothera*, together contain about two-score species, most of which apparently agree with the above in constituents and properties.

Jussieua, a genus of about 40 species of plants, of similar appearance to that of the Evening Primroses, mostly tropical American, agree closely in constituents and properties, as do most of the 160 species of *Epilobium*. *E. hirsutum* L. is the *St. Anthony's herb* of antiquity. *E. angustifolium* L., now separated from this genus as *Chamænerion a.*—(L.) Scop. (*E. spicatum* Lam.), is one of the American *Fire-weeds*, largely used in the household as an intestinal astringent. It is also known as the *Great* or *Spiked willow-herb*, *Bay-willow*, *Flowering-willow*, *Purple rocket*, *Wickup*, or *Wicopy*. It is a perennial herb, 4 to 8 feet high, the stem usually simple, densely clothed with alternate leaves which are narrowed into a petiole-like base, 3 to 6 inches long, lanceolate, acuminate, obscurely toothed, thin, and smooth. The flowers are in a long, terminal, often branched, raceme-like spike, handsome, of a light rose-purple, the ovary enclosed in the calyx-tube, calyx and corolla each 4-parted, stamens 8 and declined, like the style. The capsule is quadrangular, linear, and contains numerous cottony-tufted seeds.

Several species of *Ludwigia* are used as expectorants and diuretics. The seeds of *Trapa natans* L. are eaten in Oriental countries under the name *Water chestnut* or *Jesuit-nut*.

ONONIS.—Ononis.

Radix ononidis, P. G.; *Radix restis bovis.—Petty whin, Rest-harrow, Stay-plow*, E.; *Ochsenbrechkraut, Hanhechel*, G.; *Bougraue*, Fr.

The dried root of *Ononis spinosa* L. (Fam. *Leguminosæ*).

Origin and Description.—This is the root of a perennial herb growing in sandy soil throughout a large part of Europe. It is about 60 Cm. (2 Ft.) long, 1 to 2 Cm. ($\frac{2}{5}$—$\frac{4}{5}$ In.) thick, slightly branched, many headed, tough-woody, and mostly curved and of a flattened and twisted appearance. It has a deeply wrinkled, dark gray-brown thin bark and an irregular whitish, tough, fibrous meditullium with numerous medullary rays. It has a faint odor resembling that of liquorice-root, and a mucilaginous, sweetish, afterward bitterish and disagreeable taste.

Constituents.—Besides the peculiar body *ononid*, believed to be altered glycyrrhizin, it contains the glucoside *ononin* ($C_{30}H_{34}O_{13}$), which is finely crystalline, colorless, and tasteless, slightly soluble in boiling water and with difficulty in alcohol, and insoluble in ether. *Onocerin* ($C_{12}H_{20}O$) is very similar.

Action and Uses.—Ononis is occasionally prescribed in conjunction with juniper, squill, and potassium acetate in the treatment of dropsical conditions and chronic rheumatic affections. Formerly it was recommended as an external application to hemorrhoids, variocele, and cutaneous eruptions. The glucoside "ononin" may be given internally in doses of from 3 to 5 grains (0.19–0.32 Gm.).

OPII PULVIS, *U. S.*—Powdered Opium.

Poudre d'opium, Fr.; *Opiumpulver*, G.

Preparation.—The U. S. Pharmacopœia directs that opium shall be dried at a temperature not exceeding 85° C. (185° F.) and reduced to a very fine powder.

Powdered opium, for pharmaceutical and medicinal purposes, when assayed by the process given under Opium, should yield not less than 12 nor more than 12.5 per cent. of crystallized morphine. If of a higher percentage, it may be brought within these limits by admixture with powdered opium of a lower percentage, or powdered sugar of milk in proper proportions.—U. S.

Action and Uses.—For the action and uses of powdered opium, see Opium.

OPIUM, *U. S., Br., P. G.*—Opium.

Meconium, Succus thebaicus, Lachryma Papaveris.—Opium, E., Fr., G.; *Extractum Thebaicum*, Dan.; *Meconium, Laudanum*, Russ.; *Oppio*, It.; *Opio*, Sp.

The concrete milky exudation obtained by incising the unripe capsules of *Papaver somniferum* L. (*P. officinale* Gmel.; *P. album* Mill.—Fam. *Papaveraceæ*), and yielding, in its normal moist condition, not less than 9 per cent. of crystallized morphine, when assayed by the U. S. P. process.

Opium is official in all pharmacopœias, which differ considerably in their definitions. That of the B. P. merely requires that it be obtained by incision from the unripe cap-

sules of the species named and inspissated by spontaneous evaporation. This is followed by a provision that any suitable variety may be used for the tincture and extract (which are of standard alkaloidal strength), yielding when dry not less than 7.5 per cent. of anhydrous morphine; for other official purposes the morphine yield must be not less than 9.5 nor more than 10.5 per cent. That of a higher yield may be diluted with that of a lower, which, however, must contain between 7.5 and 10 per cent., or with milk-sugar. This exclusion of very low-grade opium, even for mixing purposes, is doubtless based upon the idea that such an article differs from the better not only in its smaller content of morphine but also in its greater content of other and undesirable alkaloids, which generally compensate to a certain extent for the absence of the morphine. The P. G., which mixes badly the definition and description, requires (as do most pharmacopœias) that opium be collected in Asia Minor, that it yield from 10 to 12 per cent. of morphine, and that it lose not more than 8 per cent. of moisture when completely dried at a temperature of 100° C.

Very interesting questions have arisen as to whether an article is to be regarded as conforming to the definition when, although it yield the required percentage of morphine, it contains some foreign substance, such as starch or chopped vegetable tissue, intentionally added as a diluent, but itself inert. It would seem as though a negative answer should be returned, so far as relates to those pharmacopœias which specify certain substances which may be used as diluents, as does the B. P. This the U. S. P. does not do under this title, though it does so under Opii Pulvis.

Origin and Production.—The production of Opium of the official grade was in the past confined almost exclusively to Asia Minor, and this article has been distinguished as "Turkish," "Constantinople," or "Smyrna," often as "Medicinal" opium. During recent years the quality of opium elsewhere produced has greatly improved, and it is said that much other than the Turkish now reaches the official standard. Notwithstanding these facts, Turkish opium is still far superior to other commercial varieties, and through custom, and because of superior qualities other than the morphine content, as well as because of technical conformity to the official description, it still supplies the great bulk of the article medicinally employed.

The successful production of opium requires a rich soil, heavily fertilized, thorough tillage, and painstaking care. In the seasons of sowing and time required for maturity, the opium crop is strikingly similar to wheat, as grown in America, there being a "winter" and a "spring" crop. The winter crop is sown in September, and is expected to be protected during the winter season by a covering of snow. Failure in such protection subjects it to a heavy loss by winter killing. It may then be sown again in February or March, but a successful crop is dependent upon exceptionally favorable conditions, especially as to an abundance of rain falling just at the right time. In any case, this crop is usually inferior to the former. During the entire period, including that of harvesting, the crop is subject to great climatic vicissitudes. Although there are varieties of opium dependent upon the color of the flowers, it is said that a field usually displays flowers of all colors from white to deep red, though the "black" variety, with red flowers and black (occasionally white) seeds, predominates. Each plant produces from 5 to 20 capsules. When these are just turned of a pale-yellow color, the time for incision has arrived, and this is performed in the late afternoon. The capsule (see Papaver) contains a dense network of laticiferous vessels underneath the epidermis, which at this time are distended with milk-juice, which escapes when an incision is made. In Asia Minor these incisions, 1 to 3 in number, are spirally transverse, entirely encircling the capsule, and made by a knife possessing the same number of blades. Great skill is required in performing this process, a too-shallow incision failing to secure all the milk, a too-deep one permitting the milk to enter the cavity, resulting in its loss as well as that of the seeds. The following morning the juice has thickened sufficiently for collection and is scraped off by a blunt knife and transferred to a poppy-leaf held in the left hand. Often a second scarification is made a day or two later. To decrease the adhesiveness of the opium the collector is said to apply his saliva from time to time to the edge of the knife. Owing to local differences in the performance of this scraping process the opium may (*Smyrna Opium*) or may not (*Constantinople Opium*) contain a certain amount of the epidermis of the capsule. This admixture naturally amounts to from 5 to 8 per cent., but advantage is taken of its presence to add considerable quantities of chopped vegetable tissues, so much as 33 per cent. having been extracted from

an opium which, however, yielded the standard percentage of morphine. The treatment of the opium at this stage is subject to considerable variation in different districts and by individual producers, chiefly for the purpose of adulteration or dilution (see *Adulterants*). In some places it is beaten up to a homogeneous mass, and the practice of diluting an excessively rich article with one of lower grade is very common. The grade of Turkish opium called "Adeth" (meaning *usual* or *ordinary*) yields almost uniformly 9.5 per cent. of morphine. Besides the differences in morphine content, there are other differences of color, consistency, and especially of aroma and flavor, which are regarded as important, especially for exportation to China for chewing or smoking purposes.

The masses thus collected are subjected to a drying process, conducted chiefly in the shade. Too long continued, this results in an undue loss of weight; too incomplete, it subjects the article to the great danger of mouldiness, a common defect in the commercial article. The poppy leaf is now wrapped about the mass and the latter is packed in the capsules of a species of Rumex.

Almost every country in the world, the climate of which has offered any possibility of success, has attempted the production of Opium. Although most of them have not yet succeeded in producing an article of equal quality with that of the Turkish, many have demonstrated the probability that this could be done by the exercise of sufficient care and after full experience. Several, while producing an article of inferior grade, produce amounts far larger than that of the Turkish. While the best of such Opium is utilized in morphine manufacture, the great bulk of it is employed in the vicious practices of chewing and smoking, in which vices China occupies the first place. Since the variations in Opium depend upon climate and methods of production, the names assigned to the varieties are almost wholly geographical. Although most of the unofficial opiums are rarely or never seen in the United States, brief reference is here made to all the more important sorts. Neither in America nor Europe is the article produced upon a commercial scale, although in both opium of a high quality (containing about 20 per cent. of morphine) has been produced, the cultivation in Europe extending as far north as Sweden. In both places it is the cost of production rather than natural difficulties which bars development of the industry. The same statement may be made regarding Australia.

Bulgarian Opium, though produced to only a trifling extent, is of interest because of its high quality. Four samples exhibited at the Antwerp Exhibition in 1896 were found to contain respectively 7.25, 11.90, 11.07, and 19.15 per cent. of morphine.

Egyptian Opium is prepared in a manner very similar to the Turkish, but it is somewhat harder and of a dark color. Its quality is extremely variable, the morphine percentage ranging from almost nothing up to near the official average.

In other parts of Africa, especially in the countries adjacent to the Mediterranean, trifling amounts are produced.

Persian Opium is produced in large quantity and is of considerable importance, much of it being exported to the United States and London for the manufacture of morphine, of which it frequently yields 12 per cent. or more. It is commonly wrapped in paper, the paper often marked with Chinese characters, in cylindrical sticks, often in cones or balls, and packed in chopped dry Poppy refuse. This opium has an oily appearance, both internally and externally, due to the collectors' custom of employing oil to prevent the adhesion of the opium to their tools. Persian Opium is far more subject than other sorts to change of appearance due to manipulation. For the Chinese market, such manipulation is accompanied by heavy adulteration, while for Europe and America it is done more to alter its appearance and cause it to resemble the Turkish article. Persian opium is notable for exhibiting more crystals than the Turkish, these being often visible to the naked eye.

Indian Opium, though second only to the Chinese in extent of production, is of little interest in Materia Medica proper, since very little of it is exported, except that known as *Provision Opium*, which is sent to China for vicious uses. The greater part of it falls far below the official standard, though the Patna product is said to frequently attain thereto. It yields upward of 70 per cent. of extract, against about 50 per cent. from the official. Its collection is very similar to that of the Turkish, though vertical incisions are made in the capsules. It contains much moisture, said to be owing to the heavy dews that fall upon it; and it is apparently subject also to more or less fermentation, which imparts to it a peculiar odor. It is either wrapped in oiled paper or enclosed in

small cases made by glueing together poppy leaves with an adhesive substance, made partly from a poppy plant extract, partly from a dark juice which exudes from the opium during its preparation. Like the Persian, it is distinguished by the conspicuousness of its crystals.

Chinese Opium, which is produced to the enormous extent of about 40,000,000 pounds annually, probably double the total production of all other kinds, is wholly consumed at home, together with great quantities imported from India, Persia, and elsewhere. Up to a comparatively recent period, Chinese opium was notable for its low morphine percentage and general poor quality, thus giving a high preference to the Indian importations. Of late, earnest attention has been given to the improvement of its quality, with a consequent heavy decline in the importations referred to.

Consumption and Commerce.—The world's average annual consumption of Opium for medicinal purposes is estimated at about 5500 cases. This amount is really trifling as compared with its use for vicious purposes, though such latter use relates chiefly to other varieties. In the United States the illicit use of Opium is less extensive than in other countries and its medicinal relations are of prime importance. The opium trade is influenced by very many and diverse conditions and is complicated and difficult to follow. Importations into the United States have been of the most irregular character, determined chiefly by the frequent changes in the tariff. Upon the one hand, anticipation of such changes has frequently induced heavy speculative buying or its cessation; upon the other, the high duty frequently charged has, while not decreasing the amount of importations, heavily increased smuggling.

Description.—In irregularly globular, usually more or less flattened masses, weighing from 250 to 1000 grams ($\frac{1}{2}$–2 lbs.), the surface marked with the impression of a poppy leaf used for wrapping, and frequently bearing fragments of this and some Rumex fruits, of a chestnut brown or reddish brown, changing to dark or blackish brown with long keeping; plastic and rather soft or gradually hardening from without inward, with age; fractured surface exhibiting more or less tissue-fragments, together with small tear-shaped particles of opium and, under the microscope, some acicular crystals, especially visible after moistening with benzene; of a heavy narcotic odor and taste, the latter disagreeable and bitter. The required morphine percentage has been stated under *Definition*. The ash residue is too irregular to be characteristic. The character of the tissue fragments, as pertaining to the epidermis of the capsules, is regarded as characteristic of Smyrna opium.

Various provisions are found in the different pharmacopœias regarding the percentage of moisture, and the ash, which, according to the Russian, shall not exceed 8 per cent. and shall not effervesce with hydrochloric acid. The Russian states that a drop of ferric chloride added to the filtrate of Opium shaken up with water should color it dark red. The Norwegian requires that 2 grams, shaken up with 25 Cc. of warm water, should not be ropy nor mucilaginous after cooling. The Dutch requires a yield of 50 per cent. of dry extract, the French the same amount of thick extract.

Adulterants.—The introduction to Opium of inert substances intended to reduce its morphine strength, has been discussed under *Production*. Very similar may be considered the addition of an extract of capsules, or a mass consisting of the latter finely beaten up with water, both of which contain some morphine, or of an extract of the herbage, which is practically destitute of that constituent. The latter method of adulteration is of great antiquity, but is now little practised. The practice, formerly very common, of introducing stones, bullets, nails, and other heavy objects, has also been largely eliminated as a result of improved commercial precaution. Some years ago a good deal of interest was excited in the manufacture in the United States of a "pudding" or so-called *Boston* opium, mixed up with the sole object of bringing the morphine percentage down to the official limit. Except for its reduced strength, this article was of good appearance and quality. It seems now to be rarely or never seen. In 1882 Stevenson reported upon a sample of spurious Opium, consisting chiefly of Aloes, which, by suitable mixing and interment in the earth for a month and a half, had largely lost the odor of aloes. Various kinds of resinous, saccharine, and mucilaginous substances, ashes, clay, gypsum, sand, and litharge have been employed, and in some cases merely added to an Opium from which the morphine had been mostly or wholly extracted. For reference to an undue amount of moisture, see *Constituents*.

Examination.—Hager suggested the following course for determining the presence of adulterants: The sample is dried and powdered, and 25 grains of the powder are

triturated with ½ ounce of boiling water; the formation of a stiff paste or mucilaginous liquid would indicate the presence of starch, flour, gum, or salep. 2 ounces of water are added, and the liquid filtered; the filtrate should be of a wine-yellow color, indicating the absence of liquorice or other aqueous extracts, which would impart to the filtrate a brown color; the liquid should likewise have an acid reaction, otherwise the admixture of chalk, litharge, or ashes may be inferred. On evaporating the filtrate to 1 ounce, potassium ferrocyanide or the addition of twice its bulk of alcohol should not cause any precipitate; the former test would indicate the presence of salts of heavy metals; the latter an adulteration with gum or certain salts. The insoluble residue of opium left on the filter after washing and drying should weigh between 10 and 11½ grains; should it weigh more, sand, clay, or other insoluble substances may be present, and in case it weighs less, sugar, gum, or other soluble impurities are indicated. On agitating powdered opium with chloroform the mineral impurities and starch settle to the bottom, and the latter acquires a blue color on the addition of a little iodine. Mineral impurities are likewise indicated by the amount of ash left, which for genuine powdered opium is about 6 per cent., varying, however, between 4 and 8 per cent.

Constituents.—Opium is entirely free from starch and tannin. Among the principles ordinarily found in plants, the following have been observed in opium: an odorous principle, soluble in ether, benzene, and petroleum-benzin; glucose, gum, pectin, a compound resembling caoutchouc, wax, fat, a small amount of resin, coloring-matter, and that indefinite substance usually designated as "extractive." The mineral constituents average about 6 per cent. The important constituents are the alkaloids. Their total number is uncertain, since some of those reported have been imperfectly described, and it is not certain that they are not mixtures. It is not likely, however, that the known alkaloids of opium are less than 20 in number, though apparently they do not all occur in all varieties of the drug. Of these, morphine is by far the most important, not only because its amount renders it the overwhelming physiological agent, but because its action and uses are far more numerous and important than those of all the other constituents combined. Codeine probably stands next in importance to morphine. Since both these alkaloids, together with their derivatives, Apomorphine and Apocodeine, are described under separate titles, they will not be here considered, except as to their occurrence. It is now pretty well established that they exist in opium partly as sulphates and partly as acid meconates. The percentage of morphine varies, in natural opium, from less than 1 to nearly 25 per cent. The official and legal requirements as to its percentage have been stated. The ordinary Turkish opium of the New York market almost always contains in the neighborhood of 10.5 or 11 per cent. The amount of codeine ordinarily is somewhat more than 1 per cent. Of the remaining alkaloids, the percentage is extremely variable. Of Thebaine, Narceine, Papaverine, and Pseudomorphine, the respective amounts vary from about 0.2 to about 1 per cent. That of narcotine is several times greater, more than 10 per cent. having been frequently reported. All the others exist only in minute amounts. The proportion in which the alkaloids are present is, without doubt, largely influenced by the climate, the nature of the soil, and the treatment to which the milk-juice is exposed in obtaining the opium.

Narcotine ($C_{22}H_{23}NO_7$ or $C_{19}H_{14}NO_4(OCH_3)_3$), discovered by Derosne in 1803, may be extracted with ether from the precipitate produced by ammonia in the aqueous infusion of opium, and from the insoluble residue of the latter by exhausting it with hot acetic or dilute hydrochloric acid. It crystallizes in tasteless, colorless, shining, rhombic prisms or white needles, melting at 176° C. (349° F.) and dissolving at about 15° C. (59° F.) in 100 parts of 85 per cent. alcohol, 33 parts of absolute ether, 2.7 parts of chloroform, 310 parts of amylic alcohol, or in 22 parts of benzene. It requires 7000 parts of boiling water for solution and is insoluble in cold dilute acetic acid. It is a weak base, probably existing free in the drug, and yields mostly uncrystallizable salts, which have a bitter taste and an acid reaction. Chloroform dissolves the alkaloid from the aqueous solutions of its salts. Solution in cold sulphuric acid is colorless, but turns slowly to yellow, orange, and red; it gives a blood-red color with a mixture of sulphuric and nitric acids. When boiled for a long time with water or heated with nitric acid, it is decomposed into *meconin*, $C_{10}H_{10}O_4$, and *cotarnine*, $C_{12}H_{13}NO_3$, which is a stronger base, soluble in ammonia, fusible in boiling water, and, on being boiled with very dilute nitric acid, is converted into *cotarnic* and *apophyllic acids*, the latter containing nitrogen. On heating narcotine with manganese dioxide and dilute sulphuric acid, cotarnine is obtained, and in

addition thereto *opianic acid*, $C_{10}H_{10}O_5$, which crystallizes in needles and fuses at 140° C. (284° F.). When heated with hydrochloric or hydriodic acid, it parts with 1, 2, or 3 methyl groups (CH_3) and yields new bases. Wright and Beckett have shown that it may be converted into *vanillin*. According to Wegscheider, opianic acid, heated above its melting-point, yields an anhydride, $C_{30}H_{28}O_{14}$, which by moderate fusion with potassium hydroxide is converted into meconin and *hemipinic acid* ($C_{10}H_{10}O_6$), and on treating the latter under pressure with HCl, isovanillic and protocatechuic acids are obtained.

Narceine ($C_{23}H_{29}NO_9 + 2H_2O$), discovered by Pelletier in 1832, occurs in long quadrangular prisms or white silky needles, which have a slightly bitter taste, melt, when anhydrous, at 145.2° C. (291.6° F.), are insoluble in ether, and are sparingly soluble in cold alcohol and water. Fröhde's reagent renders it brown green, afterward yellow and reddish. Erdmann's test produces a deep-yellow, brown-yellow, and, finally, a deep-orange color. Iodine, not used in excess, produces a blue, nitric acid a rapidly fading yellow color. Narceine is a weak base, and yields crystallizable salts which are mostly not freely soluble in water or are decomposed by water, the hydrochloride yielding a highly basic salt.

Thebaine, or paramorphine ($C_{19}H_{21}NO_3$), was discovered by Thiboumery in 1835. It forms silvery scales or hard prisms; is soluble in ether, more freely in alcohol, amylic alcohol, benzene, and chloroform, but nearly insoluble in water and alkalies. It is colored blood red, afterward yellow, by sulphuric acid, yellow by nitric, orange red by Erdmann's test, orange yellow, and finally colorless by Fröhde's reagent, and red brown by chlorine-water and ammonia. The salts of thebaine crystallize readily. Diluted acids readily alter the alkaloid, yielding two amorphous isomeric bases, *thebenine* and *thebaicine*, which are sparingly soluble in hot alcohol and insoluble in other simple solvents.

Papaverine ($C_{20}H_{21}NO_4$), discovered by Merck in 1848, forms colorless needles or prisms, which are slightly soluble in cold ether and alcohol, but readily soluble in hot alcohol, amylic alcohol, chloroform, and benzene. It melts at 147° C. (296.6° F.). Nearly all its salts are sparingly soluble in cold water and dilute acids, and its solutions part with the alkaloid on being agitated with chloroform. Warm sulphuric acid colors it deep purple or violet blue. Fröhde's reagent renders it bright violet blue, then blue, yellowish, and finally colorless.

Pseudomorphine, also known as *phormine*, *oxydimorphine*, and *dehydromorphine*, was discovered by Pelletiêr and Thiboumery (1835). It is a derivative of morphine, and probably does not pre-exist in opium, being readily formed by the action of oxidizing agents on alkaline solutions of that base. Its production is said to be due to the removal of an atom of hydrogen from each of two molecules of morphine and the subsequent union of the two residues, thus: $2C_{17}H_{19}NO_3 - H_2 = C_{34}H_{38}N_2O_6$. Pseudomorphine occurs as a fine crystalline powder, insoluble in water, alcohol, ether, and chloroform, but dissolves in acetic acid and in solutions of the alkali hydroxides, and is said to be also soluble in benzene. With mineral acids it forms salts sparingly soluble in water. Pseudomorphine is of special interest and forensic importance, as it is a non-poisonous base, and while its reactions with nitric acid and with ferric chloride are very similar to those of morphine, it may be distinguished from the latter by the green coloration developed upon mixing pseudomorphine with concentrated sulphuric acid and adding a drop of formaldehyde solution or a few grains of sugar.

Rhœadine, $C_{21}H_{21}NO_6$, discovered by O. Hesse in 1865, is in white tasteless prisms which are nearly insoluble in ether, alcohol, benzene, chloroform, water, and ammonia, and which yield with dilute acids tasteless and colorless solutions, acquiring an intense purple color on the addition of strong hydrochloric or sulphuric acid. Besides the coloring-matter, an isomeric, bitter, colorless base, *rhœagenine*, is formed in this reaction. The color produced by acids with Merck's *porphyroxin* (1837) depends on the presence of some rhœadine.

Cryptopine, $C_{21}H_{23}NO_5$, was discovered by T. and H. Smith in 1867. It crystallizes in minute prisms, is sparingly soluble in water, ether, benzene, and cold alcohol, dissolves in potassa and chloroform, and forms bitter salts, which have a pungently cooling taste, and when dissolved in hot water usually produce a jelly-like mass, which is gradually changed to crystals. Sulphuric acid colors it yellow, soon turning violet color, but in the presence of minute traces of ferric salt or of chlorine a dark violet-blue color is at once produced, which on warming turns dingy green.

Oxynarcotine, $C_{22}H_{23}NO_8$, was isolated from the mother-liquors of narceine by Wright and Beckett (1876). It dissolves in alkaline liquids, but is nearly insoluble in benzene, chloroform, and hot alcohol and water. Like narceine and narcotine, it yields *hemipinic acid.*

Gnoscopine, $C_{22}H_{23}NO_7$, was found by T. and H. Smith (1878) in the mother-liquors of narceine. It forms thin needles of a woolly appearance, melts with decomposition at 233° C., is soluble in chloroform and carbon disulphide, slightly soluble in benzene, and is insoluble in petroleum and in fusel oil. Sulphuric acid dissolves it with a yellowish color, becoming carmine red with a trace of nitric acid.

The following alkaloids were discovered by O. Hesse (1870 and 1871), and may be prepared from the mother-liquors left in the preparation of morphine by Gregory's method.

Lanthiopine, $C_{23}H_{25}NO_4$, is crystalline, tasteless, sparingly soluble in acetic acid, alcohol, ether, and benzene; is readily soluble in chloroform; is colored orange red by nitric and pale violet by sulphuric acid, the latter color changing to dark brown on heating.

Meconidine, $C_{21}H_{23}NO_4$, is amorphous, colorless or yellowish, tasteless, easily soluble in alcohol, ether, benzene, chloroform, and acetone. It yields very bitter unstable salts, and is dissolved by sulphuric acid with an olive-green, and by nitric acid with an orange-red color.

Laudanine, $C_{20}H_{25}NO_4$, crystallizes in hexagonal prisms, melts at 166° (331° F.), is sparingly soluble in ether and cold alcohol, soluble in benzene, chloroform, and alkalies; in ferric chloride with an emerald-green, in nitric acid with an orange-red, and in sulphuric acid containing iron with a rose-red color, the latter changing to violet on heating. The hydriodate is sparingly soluble in cold water; the hydrochlorate is nearly insoluble in solution of sodium chloride.

Codamine, $C_{20}H_{25}NO_4$, crystallizes from ether in large 6-sided colorless prisms; is easily soluble in chloroform, benzene, ether, alcohol, and boiling water; forms amorphous bitter salts, and dissolves in nitric acid with a dark-green, and in sulphuric acid containing iron with a blue color, changing to green and dark violet on warming.

Laudanosine, $C_{21}H_{27}NO_4$, is soluble in alcohol, chloroform, ether, and warm benzol; the crystals fuse at 89° C. (192.2° F.). It neutralizes acids, and yields with hydriodic acid a sparingly soluble salt. Pure sulphuric acid colors rose red, in presence of ferric salt brown red, on warming, green and deep violet.

Protopine, $C_{20}H_{19}NO_5$, resembles cryptopine, and is with difficulty soluble in ether, alcohol, and benzene, more readily soluble in chloroform. The solutions of its salts do not gelatinize and have a bitter taste. The solutions in sulphuric acid turn yellow, red, and purple; in presence of ferric salt they are deep violet.

Hydrocotarnine, $C_{12}H_{15}NO_3$, crystallizes in large colorless prisms, fuses at 55° C. (131° F.); volatilizes, partly unchanged, at 100° C. (212° F.); is easily soluble in benzene, ether, and alcohol, and forms readily soluble salts. It is formed from narcotine, besides meconin, by the action of nascent hydrogen.

Tritopine ($C_{42}H_{54}N_2O_7$), discovered by Kander in 1890, occurs in prismatic crystals, soluble in chloroform, slightly in ether.

Xanthaline ($C_{37}H_{36}N_2O_6$) was described by T. and H. Smith in 1881.

From many of the above alkaloids derivatives have been obtained which are highly interesting from a scientific point of view, and which prove that at least between some of them there exists a close relation. It is not unlikely that some of those enumerated above are the decomposition-products of others. This may most likely be affirmed to be true of Wittstein's *metamorphine* (1860), which was obtained in preparing morphine by Mohr's process, but has not been observed since. It liberated iodine from iodic acid, was colored red by nitric acid, but was not affected by ferric chloride. Hinterberger's opiane was proved by Hesse to be impure narcotine.

Meconic acid ($C_7H_4O_7$), long official in the B. P., discovered by Sertürner, is obtained by precipitating the concentrated infusion of opium with calcium chloride, and treating the calcium meconate repeatedly with warm diluted hydrochloric acid. It crystallizes in micaceous scales or rhombic prisms containing $3H_2O$, dissolves in 4 parts of boiling water, and is also soluble in alcohol. Opium yields 3 to 4 per cent. of it. It is a tribasic acid, and imparts to ferric salts a deep-red color, which does not disappear on the addition of dilute hydrochloric acid (difference from formic and acetic acids) or by

the chlorides of gold or of mercury (difference from sulphocyanates). When boiled with water, or more rapidly when boiled with dilute hydrochloric acid, meconic acid is decomposed into carbon dioxide and crystallizable *comenic acid*, $C_6H_4O_5$, which on being heated yields a sublimate of *pyrocomenic acid*, $C_5H_4O_3$. The two derivative acids likewise reddeu ferric salts, the last less deeply than the former. Lactic acid also occurs.

Meconin is obtained from narcotine (see above), exists also in opium, and forms colorless shining prisms, which are inodorous, bitter, soluble in alcohol, ether, and slightly soluble in water. It was discovered by Dublanc (1832), and is also known as *opianyl*. It melts in water at 77° C. (170.6° F.) and in the air at 110° C. (230° F.), and when evaporated with slightly diluted sulphuric acid gives a green color.

Meconoisin ($C_8H_{10}O_2$) was obtained by T. and H. Smith (1878) from the mother-liquors left on the isolation of meconin, from which it separates in an impure state as brown leaf-like crystalline masses. When pure it is colorless, is freely soluble in alcohol, ether, and hot water, fuses at 88° C. (190.4° F.), and on evaporation with dilute sulphuric acid yields a red color, changing to purple.

Assay of Opium.—The U. S. P. gives the following process for determining the morphine-content of opium: opium, in any condition to be valued, 10 Gm.; ammonia-water, 3.5 Cc.; alcohol, ether, distilled water,, lime-water of each, a sufficient quantity. Introduce the opium, which, if fresh, should be in very small pieces, and if dry, in very fine powder, into an Erlenmeyer flask having a capacity of about 300 Cc., add 100 Cc. of distilled water, cork it well, and agitate every 10 minutes, or in a mechanical shaker, during 3 hours. Then pour the whole as evenly as possible upon a wetted filter having a diameter of 12 Cm., and, when the liquid has drained off, wash the residue with distilled water, carefully dropped upon the edges of the filter and its contents, until 150 Cc. of filtrate are obtained. Then carefully transfer the moist opium back to the flask by means of a spatula, add 50 Cc. of distilled water, agitate thoroughly and repeatedly during 15 minutes, and return the whole to the filter. When the liquid has drained off wash the residue, as before, until the second filtrate measures 150 Cc., and finally collect about 20 Cc. more of a third filtrate. Evaporate in a tared capsule, first the second filtrate to a small volume, and then add the first filtrate, rinsing the vessel with the third filtrate, and continue the evaporation until the residue weighs 14 Gm.

Rotate the concentrated solution about in the capsule until the rings of extract are dissolved, pour the liquid into a tared Erlenmeyer flask having a capacity of about 100 Cc., and rinse the capsule with a few drops of water at a time until the entire solution weighs 20 Gm. Then add 10 Gm. of alcohol, shake well, add 25 Cc. of ether, and shake again. Now add the ammonia-water from a graduated pipette or burette, stopper the flask with a sound cork, shake it thoroughly during 10 minutes, and then set it aside, in a moderately cool place, for at least 6 hours or over night.

Remove the stopper carefully, and should any crystals adhere to it, brush them into the flask. Place in a small funnel 2 rapidly acting filters, of a diameter of 7 Cc., plainly folded, one within the other (the triple fold of the inner filter being laid against the single side of the outer filter), wet them well with ether, and decant the ethereal solution as completely as possible upon the inner filter. Add 10 Cc. of ether to the contents of the flask, rotate it, and again decant the ethereal layer upon the inner filter. Repeat this operation with another portion of 10 Cc. of ether. Then pour the liquid in the flask into the filter, in portions, in such a way as to transfer the greater portion of the crystals to the filter, and, when the liquid has passed through, transfer the remaining crystals to the filter by washing the flask with several portions of water, using not more than about 15 Cc. in all. Use a feather or rubber-tipped glass rod to remove the crystals that adhere to the flask. Allow the double filter to drain, then apply water to the crystals, drop by drop, until they are practically free from mother-liquor, and afterward wash them, drop by drop, from a pipette, with alcohol previously saturated with powdered morphine. When this has passed through, displace the remaining alcohol by ether, using about 10 Cc. or more if necessary. Allow the filter to dry in a moderately warm place, at a temperature not exceeding 60° C. (140° F.) until its weight remains constant, then carefully transfer the crystals to a tared watch-glass and weigh them.

Place the crystals (which are not quite pure) in an Erlenmeyer flask, add lime-water (10 Cc. for each 0.1 Gm. of morphine), and shake the flask at intervals during half an hour. Filter through two counterpoised rapidly acting filters, one within the other as directed above. Rinse the flask with more lime-water and wash the filters with the same fluid until the filtrate, after acidulating, yields no more precipitate with mercuric potassium iodide test-solution. Press the filters until nearly dry between bibulous paper and dry them to constant weight, and weigh. Deduct the weight of the insoluble matter remaining on the filter from the weight of the impure morphine previously found. The difference multiplied by 10 represents the percentage of crystallized morphine contained in the opium.—U. S.

As it is not always convenient to maintain a temperature at or not exceeding 60° C. (140° F.) during the drying of the crystals, this operation may be carried on on a boiling water-bath for 4 hours or in an air-bath at 110° C. (230° F.) for 2 hours, to constant weight. In this way the crystals of morphine will be rendered anhydrous, which will necessitate multiplication of the weight by 1.063, in order to get the result in terms of hydrated crystals, as demanded by the Pharmacopœia.

The assay process of the British Pharmacopœia differs materially from the above. It consists in treating powdered opium with milk of lime for half an hour, then filtering the mixture, adding alcohol and ether to an aliquot part of the filtrate, and finally liberating the morphine by addition of ammonium chloride. After washing the crystals of morphine with morphinated water they are dried to an anhydrous condition, weighed, and titrated with decinormal sulphuric acid. A correction factor is added to the final result to compensate for average loss of morphine during the process, 10 per cent. of anhydrous morphine being demanded as the official standard. This method of assaying opium, better known as the "lime method," is in favor with many operators, and has the advantage of greater purity of the morphine obtained, the latter being wholly soluble in 10 times its weight of lime-water; it also requires less time than the U. S. P. method. The weak point of the lime method lies in the fact that the increase of volume of the liquid may not always be uniform, and the solubility of morphine in the mother-liquor and wash-water may vary with different samples of opium, for which reasons an average has been decided upon in both cases. For details of this process see *Proc. Amer. Pharm. Assoc.*, 1902, p. 425.

Pharmaceutical Preparations.—Camphorated Tincture of Opium, Deodorized Opium, Extract of Opium, Pills of Opium, Powder of Ipecac and Opium, Tincture of Deodorized Opium, Tincture of Opium, Troches of Licorice and Opium, Vinegar of Opium, Wine of Opium, U. S. P.

Action and Uses.—When opium is taken internally in moderate medicinal dose, it produces a sense of mental and physical rest which differs in its degree. In some instances the patient describes the sensation as exceedingly agreeable; in other instances this period of well-being is very slight, and the second effect, that of drowsiness or sleep, is developed. The danger of this sleep depends largely upon the susceptibility of the patient and the size of the dose. Some persons are made wakeful by doses which would put ordinary persons to sleep, and rarely extreme susceptibility is present, so that deep sleep is caused by very small doses. The sleep is usually dreamless, or if dreams are present they are commonly of an agreeable type. On waking, the patient may feel greatly refreshed, or if susceptible to the after-effects of the drug he may be immediately or after several hours depressed, nauseated, and may even vomit. This effect is produced not by the opium itself, but by the oxydimorphine which is produced in the process of oxidizing the drug in the body. It is also in part due to narcotine, one of the alkaloids of opium. In some instances this secondary effect of opium is so severe as to prevent the use of the drug if it can be possibly avoided. When small doses are used, opium is entirely destroyed in the body by oxidation; but if the dose be very large, some of its alkaloidal contents escapes in the urine. If doses in excess of those which are medicinal in size are given, the sleep comes on more speedily and is more profound, but even in severe poisoning active measures will arouse the patient to some degree of consciousness as a rule. The effect of the drug in doses of this and of the smaller size is to make the pulse fuller and slower, the skin warm and dry, and the face slightly flushed. As the poisoning deepens the face becomes blue or cyanosed, from failure of respiration, and the breathing drops from the normal rate to 12 or 10 per minute. At first the respirations, though slowed, are deeper; then they become more and more shallow and more and more slow, till they cease in death. The pulse, at first somewhat slow, becomes more rapid as the poisoning advances, and the skin becomes cold and clammy when the patient is near dissolution. The pupils are tightly contracted till the moment of death, when they become widely dilated. When the patient is aroused the cyanosis disappears with the temporary increase in the respiratory activity, but as he sinks back into unconsciousness the blueness returns. The body temperature is not materially reduced till death is at hand. The treatment of opium-poisoning consists in the use of an emetic or stomach-pump, the giving of strychnine hypodermically, of strong black coffee by the mouth or rectum, to stimulate the heart, respiration, and the vital forces generally, and the giving of potassium permanganate to act as a chemical antidote on the drug while it is still in the stomach. The electric wire brush with a fairly strong current may also be used to keep the patient awake, so that he will breathe voluntarily instead of depending upon the depressed respi-

ratory centre in the medulla. If the electric brush is not obtainable, slapping with wet towels or small twigs may be used, care being taken not to bruise the patient or exhaust him by too constant walking to keep him awake. It is also important to wash out the stomach frequently, in order to remove the drug which is excreted into the viscus after it has been absorbed.

Medicinal doses of opium check secretion of all glands in the body except those of the skin and kidneys, the activity of which is sometimes increased, particularly that of the skin. Such amounts also diminish intestinal peristalsis and cause constipation by stimulating the inhibitory fibres of the splanchnic nerves and by checking the secretion of the intestinal juices. For these reasons it is a valuable remedy in watery or serous diarrhœa, but it is contraindicated in mucous diarrhœa, since it locks in the bowel discharges which should be expelled.

Opium relieves all forms of pain by directly benumbing the perceptive centres in the brain and by allaying irritation and spasm. Aside from the anæsthetic drugs it is the most powerful pain-relieving drug that we have.

Because of its pain-relieving and diaphoretic power it is used largely in the form of Dover's Powder to produce sweating in the early stages of acute diseases.

As opium checks excessive secretion, it also proves useful in diabetes mellitus and insipidus, in the former disease often in an unexplained manner diminishing the excretion of sugar.

Opium will always produce sleep if given in large enough dose, and is particularly useful in insomnia due to pain. It is not to be used in nervous insomnia, as it is apt to produce the opium-habit.

Because of its sedative effects it is often given to produce rest and to conserve energy in cases in which, because of active delirium and restlessness, the vital forces are impaired. So, too, in cases of advanced valvular disease of the heart it may be beneficial.

The opium-habit is an exceedingly common condition, arising from abuse of the drug. Its chief characteristics are the development of lack of moral sense in the patient, clever lying by him, and an insatiable desire for additional doses of the drug. It is best treated, as a rule, by isolation, and the proper use of hyoscine. The dose of gum opium is from ½ to 1 grain (0.03–0.06 Gm.), of powdered opium ¼ to 1 grain (0.015–0.06 Gm.).

OPIUM DEODORATUM, *U. S.*—Deodorized Opium.

Opium sans odeur, Fr.; *Desodorirtes Opium*, G.

Preparation.—Powdered opium, 500 Gm.; purified petroleum benzin, a sufficient quantity. Macerate the powdered opium for 24 hours in a wide-mouthed, well-closed bottle, with sufficient purified petroleum benzin to completely cover it, shaking occasionally. Decant the liquid as closely as possible, and repeat the treatment with purified petroleum benzin. Again decant the liquid and pour the contents of the bottle into a plain filter contained in a glass funnel, which should be well covered, drain, and then slowly percolate the residue with purified petroleum benzin until the latter passes without odor. Remove the filter containing the opium from the funnel and expose the powder to the open air, so that it may dry thoroughly.

Deodorized opium should be kept in well-stoppered bottles, and, when assayed by the process given under OPIUM, should be found to yield not less than 12 nor more than 12.5 per cent. of crystallized morphine.

Opium of any coarser degree of powder may be deodorized in the same manner as directed above.—U. S.

The above process, first suggested by A. E. Ebert, is decidedly preferable to the ether-process of former pharmacopœias, inasmuch as it fully deodorizes the opium without removing from it the narcotine. The odorous matter in opium, which is said to cause the nausea and discomfort in many patients, together with caoutchouc, wax, and oily substance, is effectually removed by the benzin, which latter should be of high grade, about 88° C. (190.2° F.), and thoroughly purified by the official process.

Action and Uses.—The action and uses of deodorized opium are the same as those of opium. It possesses the advantage over gum or powdered opium in that it does not so commonly produce the nausea and other unpleasant after-effects of these forms of the drug. The dose is from ¼ to 1 grain (0.015–0.06 Gm.).

OPIUM GRANULATUM, *U. S.*—Granulated Opium.

Opium grenelé, Fr.; *Granulirtes Opium*, G.

Preparation.—The U. S. Pharmacopœia directs that opium shall be dried at a temperature not exceeding 85° C. (185° F.) and reduced to a coarse (No. 20) powder.

Granulated opium, when assayed by the process given under OPIUM, should yield not less than 12 nor more than 12.5 per cent. of crystallized morphine. Granulated opium of a higher percentage may be brought within these limits by admixture with granulated opium of a lower percentage in proper proportions.—U. S.

Action and Uses.—For the action and uses of granulated opium, see OPIUM.

ORCHIDACEÆ.—The Orchid Family.

Few, if any, plants exceed the orchids in botanical and curious interest; yet the family is almost devoid of economic value, apart from VANILLA, except for its ornamental properties. More than 400 genera are recognized, and the species probably number not far from 10,000. Interest centres chiefly in the curious forms of the flowers, often simulating those of particular insects, as do the colors. In these ways, as well as by their peculiar odors, the flowers are highly adapted to insect pollination.

CYPRIPEDIUM and SALEP are the only important medicinal products, and these are elsewhere considered.

CORALLORHIZA (*Coral-root, Crawley, Turkey-claw, Chickens'-toes, Dragon's claw*) is the root and other underground portion of *Corallorhiza odontorhiza* (Willd.) Nutt. (*Cymbidium o.*—Nutt.), a peculiar, leafless, purplish-brown saprophyte, growing in deep forests, in leaf-mould, through the eastern and central United States. The stem is about 2.5 Cm. (10 In.) high, rather stout and succulent, and bears from 8 to 20 flowers of a somewhat paler color than the stem, their lips nearly entire. The drug consists of numerous small fleshy tubers, which are united by their broader sides and form many branches of different length, but of the same articulated appearance, resembling coral in arrangement. It is of a brown color externally, whitish within, and has, particularly in the fresh state, a peculiar odor and a bitterish and astringent taste. Its proximate constituents have not been ascertained, but it apparently contains a little volatile oil, tannin, and a bitter body.

C. multiflora Nutt. is similar but somewhat stouter. Its flowers are open, and the lip is deeply 3-lobed.

Angræcum fragrans Thou., of Madagascar, yields very fragrant herbage which, under the names *Faham* or *Faham tea* and *Isle of Bourbon tea*, is used as a substitute for ordinary tea. It is said to have a somewhat similar nervous effect and is employed as a stomachic and antispasmodic, much like *Cypripedium*.

Goodyera is the herbage of *Peramium ripens* (L.) Salisb. (*Satyrium r.*—L.; *Goodyera r.*—R. Br.), and to some extent of *P. pubescens* (Willd.) Mac M. These are known as *Rattlesnake* or *Net-leaved plantain*. The first named is also called *White plantain* or *Squirrel-ear*. They are peculiar little woodland herbs, their ovate leaves beautifully reticulated with white lines. They enjoy some domestic repute as alteratives.

Many plants of the family possess slight aromatic properties. The root of *Cremastra Wallichiana* Lindl., the *Nimak-kotuk* of the East Indies, is chewed for the relief of toothache.

OROBANCHACEÆ.—The Broom-rape Family.

This is a small and very curious family of saprophytes, of almost no economic value. A large part of its species have been more or less used in medicine. Some of them appear to possess some medicinal activity, but most of their use appears to depend upon fanciful ideas derived from their peculiar forms and habits. The family includes a dozen genera and 125 recognized species, according to Beck. The following are the best known in medicine:

CANCER-ROOT is a name which has been applied, evidently because of their tumid and misshapen saprophytic roots, to the 4 species next named, as well as to others, not of this family.

Leptamnium Virginianum (L.) Raf. (*Orobanche V.* L.; *Epiphagus V.* Bart.; *Epifagus Americana* Nutt.) is the *Beech-drops* or *Cancer-drops*, *Broom-rape* or *Fir-rape* (*Krebswurz*, G.; *Orobanche de Virginie*, Fr.), native of eastern North America, where it is parasitic upon the roots of beech trees. The subterranean portion consists of a subglobular scaly tuber, 12 Mm. (½ In.) or more in diameter. The stem is about 30 Cm. (12 In.) high, much branched, angular, with ovate scales at the base of the branches and flowers. The flowers are in long spicate racemes, the lower ones fertile and with a short corolla, the upper ones sterile, with a long tubular and 2-lipped corolla, about 8 Mm. (⅓ In.) long. The stamens are didynamous, and the superior capsule is 1-celled, 2-valved, and contains numerous minute seeds. All parts

of the plant have a pale purplish- or yellowish-brown color, and a disagreeable, bitter, and somewhat astringent taste. The constituents of the plant have not been investigated.

Thalesia uniflora (L.) Raf. (*Orobanche u.* L.; *Anoplanthus u.* Endl.; *Aphyllon u.* T. et G.) is the *Naked, One-flowered,* or *Pale broom-rape* or *Cancer-root,* and grows throughout most of North America, in woodlands and copses. The peduncles grow in fascicles from a very short, thick, fleshy and scaly, nearly subterranean stem, and are about 10 Cm. (4 In.) long, each terminating in a nodding flower, having a curved, tubular, somewhat 2-lipped corolla, the stamens included. The whole is pubescent and of a pale tawny-violet color.

T. fasciculatum (Nutt.) Britton, the clustered *Cancer-root,* etc., bears several erect flowers upon a peduncle.

Conofolis Americana (L. f.) Wallr. (*Orobanche A.* L. f.) is the *American broom-rape, Earth-club,* or *Squaw-drops,* and grows in oak-woods throughout the eastern and central United States. The stems are about 10 to 15 Cm. (4–6 In.) high, as thick as the finger, of a rust-brown color, scaly and fleshy, and bear singly in the axils of the scales slender, curved, 2-lipped, yellowish flowers which have 4 exserted stamens.

Various species of the Old World genus *Orobanche,* the true Broom-rapes, are used either as antispasmodics or mild astringents, as well as for fanciful reasons.

OXYGENIUM.—Oxygen.

Oxygène, Fr.; *Oxygen, Sauerstoff,* G.

Symbol, O. Atomicity bivalent. Atomic weight, 15.88.

Oxygen was discovered by Scheele (1773) and Priestley (1774). It constitutes about one-fifth of the volume of atmospheric air, the remainder being nitrogen with a small proportion of carbon dioxide. Eight-ninths of the weight of water and one-half the weight of many minerals consist of oxygen, and it is estimated that at least one-third the weight of the solid crust of the earth is made up of this element, which is the most abundant of all.

Preparation.—Oxygen may be obtained by exposing manganese dioxide, mercuric oxide, or some other metallic oxide, to a strong heat, but it is most conveniently prepared by heating a mixture of 4 or 5 parts of potassium chlorate with 1 part of manganese dioxide. At a low red heat the chlorate is completely decomposed into oxygen and potassium chloride, which remains mixed with the manganese dioxide; the latter, not being altered, may be recovered by dissolving the potassium chloride in water: $KClO_3$ yields $KCl + O_3$. Care should be taken that black antimony sulphide be not used in place of manganese dioxide, and that the mixture be free from organic compounds or charcoal, since a violent explosion would take place on the application of heat.

When manganese dioxide is mixed with potassium chlorate, oxygen is given off from the latter at a much lower temperature and more regularly than when the chlorate is heated alone. It is not definitely known what part the manganese dioxide plays in the change, as it apparently remains unaffected after the action is over. This and all similar cases are designated as action due to *catalysis.*

The oxygen should be purified before storing in receivers, by allowing it to pass through wash-bottles containing alkali. To render oxygen dry, it is passed through concentrated sulphuric acid.

Compressed oxygen is now in the market in strong steel cylinders. This is a convenient form for obtaining oxygen when large quantities are needed.

Properties.—Oxygen is a colorless inodorous gas having the density 1.1056 (air = 1). 1 liter at 0° C. (32° F.) and 760 Mm. barometric pressure weighs 1.4292 Gm. It can be liquefied (see under AER), and then it has a bluish color, boils at −181° C. under atmospheric pressure, and has the density 1.135 (water = 1). 100 volumes of water at 0° C. (32° F.) dissolve 4.1 volumes, at 15° C. (59° F.) 2.9 volumes of oxygen. 100 volumes of absolute alcohol dissolve 28 volumes of oxygen. It combines with almost all elements (argon, helium, fluorine, krypton are exceptions) either at ordinary temperature or when heat is applied. The products are called *oxides,* the act of combination is called *oxidation,* and when attended with great heat and light it is termed *combustion.*

Oxygen is essential to animal life, respiration being a process of slow combustion whereby some of the waste products of the body are oxidized to carbon dioxide, which is given off from the lungs. Carbon dioxide is food for plants, which appropriate the carbon and give off the excess of oxygen, and thus a constant proportion of oxygen and carbon dioxide is kept up in the atmosphere by the reciprocal action of plants and animals (see AER).

Ozone.—This is an allotropic modification of oxygen, formed when electric discharges take place through oxygen or air, by the slow oxidation of phosphorus in moist air, and under various other circumstances. Various electrical ozonizing machines exist, but those of Siemens and v. Babo are the best, by which air or oxygen containing 8 to 9 per cent. of ozone can be obtained. When such a mixture is cooled by liquid air or oxygen, the ozone condenses to a blue liquid containing as much as 80 per cent. of pure ozone, which is very dangerous, as it explodes very easily, forming oxygen. Ozone has the molecular formula O_3, and is a condensed form of oxygen, 3 volumes of the latter forming 2 volumes of the former. In the gaseous state it has a characteristic and penetrating odor, resembling sulphur dioxide. It gradually breaks down into oxygen, the more so as its temperature is raised, is less soluble in water than oxygen, and gradually forms hydrogen dioxide with it: $H_2O + O_3 = H_2O_2 + O_2$. As such water possesses oxidizing powers, it led to the very general but erroneous view that ozone was soluble in water, and that "ozone-water" was a very good medicinal and antiseptic agent. Ozone is soluble in some organic liquids, such as turpentine and cinnamon oils, which thus become strong oxidizers. It bleaches indigo solution, liberates iodine from potassium iodide, turns silver dark, gives a blue color with tincture of guaiac, and turns an acid (HCl) solution of meta-phenylene-diamine red much sooner than does hydrogen peroxide or nitrous acid.

The quantity of ozone in air or oxygen is determined by passing the mixture through potassium iodide solution, acidifying, and titrating the iodine set free by centinormal thiosulphate solution. 1 Cc. of the latter represents 0.00024 Gm. of ozone.

Minute quantities of ozone exist in the atmosphere, which are variable and dependent on the time of year, temperature, condition of the earth's surface, etc.

Action and Uses.—Oxygen gas is used by inhalation in medicine for the purpose of improving the condition of the blood in those diseases of the respiratory and circulatory systems which result in an imperfect supply of this gas to the tissues. It is also employed by inhalation in cases in which the use of drugs, such as the anæsthetics, for example, have impaired the respiratory function and produced cyanosis, and not infrequently it is employed by surgeons for the purpose of preventing disagreeable effects and after-effects produced by ether and chloroform; the gas being given by inhalation with the vapor of these anæsthetics.

The real value of oxygen in relieving respiratory distress in the course of pneumonia and other diseases of the respiratory system which are associated with a certain degree of cyanosis is problematical. An investigation as to the custom of physicians of large experience in the treatment of these disorders reveals the fact that they constantly resort to this gas for the relief of cyanosis and respiratory difficulty, and yet are unable to assert that it does the patient any considerable amount of good. Its use in the dyspnœa and coma due to Bright's disease and in that due to diabetes is popular, but its employment is not based upon any sound scientific reasoning; for in many of these cases the dyspnœa does not result in very great cyanosis, and is due more to toxæmia and depression than it is to any distinct interference with the absorption of oxygen by the blood.

While a number of forms of apparatus have been invented for the purpose of the inhalation of this gas, none of them are of practical value at the bedside, for the patient is so short of breath that though he needs oxygen he is usually too short of breath to be willing to submit to the use of a face mask through which he may inhale the gas. In the experience of the writer the gas is best given by permitting it to escape beneath the nostrils of the patient, so that he takes a considerable quantity of it into his lungs, with each inspiration of ordinary air.

In the use of oxygen it is important to remember that it can only be taken up by the blood in certain definite quantities, for oxygen forms a chemical compound with the hæmoglobin, and therefore it is not possible for each red blood-corpuscle to contain a greater quantity of oxygen than that which is necessarily present in oxyhæmoglobin.

Oxygen was originally introduced into medicine with the idea that it could be taken up by the blood in unlimited quantities if the opportunity was offered, and it has been employed in a host of diseases with asserted advantage with this idea in view. Thus pulmonary consumption, diabetes, albuminuria, dyspepsia, and even epilepsy have been treated by its inhalation. Needless to say, the results obtained have been *nil*, and if the patient has improved, the improvement has been due to coincidence or to the imagi-

nation of the patient. In cases of respiratory distress due to profound anæmia or hemorrhage it is evident that oxygen cannot be expected to relieve the patient materially, for the difficulty lies, not in lack of oxygen, but in the fact that the blood does not contain a sufficient number of red corpuscles to absorb the quantity of oxygen which is needful for a normal existence.

OXYMEL, *Br.*—Oxymel.

Oxymel simplex, Mel acetatum.—Oxymel simple, Mellite de vinaigre, Acètomel, Fr.; *Sauerhonig,* G.

Preparation.—The Br. P. directs 40 ounces (by weight) of liquefied clarified honey to be mixed with 5 fluidounces of acetic acid and sufficient distilled water to produce a mixture having the specific gravity 1.320. The French Codex orders 1 part of white wine vinegar to be mixed with 4 parts of virgin honey, and the mixture to be concentrated and clarified with paper pulp, and to have while boiling a specific gravity of 1.260.

Action and Uses.—This is an official form of the popular mixture of honey and vinegar, which is generally used as a gargle in sore throat. It may be prescribed as an excipient for various expectorant medicines, and particularly for squill and ipecacuanha in the form of syrup.

OXYMEL SCILLÆ, *Br., P. G., Fr. Cod.*—Oxymel of Squill.

Oxymel scilliticum.—Oxymel scillitique, Mellite de vinaigre scillitique, Fr.; *Meerzwiebelhonig,* G.

Preparation.—Squill, bruised, 2½ ounces; acetic acid, 2½ fluidounces; distilled water, 8 fluidounces; clarified honey, a sufficient quantity. Digest the squill for 7 days in a mixture of the acetic acid and distilled water. Press strongly; filter. Mix the product, which should measure about 10 fluidounces, with about 27 fluidounces of the clarified honey, or sufficient to produce oxymel of squill having the specific gravity 1.320.—Br.

The P. G. directs that 1 part of vinegar of squill and 2 parts of honey shall be mixed and evaporated to 2 parts.

The Fr. Cod. orders 1 part of vinegar of squill to be mixed with 4 parts of honey, the mixture to be clarified with paper pulp and evaporated until it has a specific gravity of 1.260.

Action and Uses.—Oxymel of squill may be substituted for syrup of squill, the properties of which it adequately represents. The dose is from 30 to 60 minims (2–4 Cc.) as an expectorant for adults, and 5 to 20 minims (0.30–1.30 Cc.) for infants and children.

P.

PALMÆ or PRINCIPES.—The Palm Family.

The Palms, comprising about 128 genera and more than 1000 species of shrubs and trees of tropical and subtropical regions, together with the Pine and Grass families, take first rank in economic importance. All three families, strangely enough, are among the very lowest of flowering plants. There are a number of Palms, any one of which, like the Coco-nut, is capable of supplying almost all human necessities. Some of the most important starch-yielders pertain to this family and are discussed under AMYLUM. Several important yielders of sugar are mentioned under SACCHARUM. The annual product of Palm oils is of great value (see OLEA PINGUIA). The young tissues of many species constitute an excellent substitute for cabbage. Many excellent and important edible seeds and fleshy fruits are produced, and great quantities of alcohol and alcoholic beverages are manufactured from Palm products. Palm wax has been considered under CERA, a balsam under RESINA DRACONIS. Least among the useful properties of the family are those pertaining to medicine. The only strongly pronounced medicinal property pertaining to the family is an anthelmintic one, illustrated by ARECA, and Coco-nut oil. The only other drug of this family worthy of special mention is SABAL, elsewhere considered.

PANAX.—Ginseng.

Kraftwurzel, G.; *Schin Seng, Jin-tian, Jin-shen*, Chin.

The roots of several species of *Panax* L.—Fam. *Araliaceæ*.

Although Ginseng is not official in any pharmacopœia and its medicinal value is almost *nil*, yet its great and growing commercial importance calls for a somewhat extended account.

Origin.—The original Ginseng is derived from *P. Ginseng* Nees (*Aralia G.* Dec. et Planch.), and is distinguished as Asiatic or Chinese Ginseng. It is a native of Manchuria and other parts of eastern Asia, and is largely cultivated there, as well as in Korea and Japan. The use of the root was so popular in China that the above-named sources of supply were found incapable of supplying the demand, and recourse was had to the American species *P. quinquefolius* L. (*Ginseng q.*, Wood; *Aralia q.*, Dec. et Planch.; *P. Ginseng* C. A. Meyer; *P. Ninsi* Thunb.), which yields the *American ginseng, Jinshang, Ninsin, Five-fingers, Garentoquen* (or *Grantogen*), or *Schinseng*. This is eagerly purchased by Chinese traders for export to China. The above-named are the two principal varieties; others are mentioned below.

The American species, in which we are chiefly interested, is a smooth perennial herb, from a very slow-growing root, described below. The stem is from 30 to 50 Cm. (1 to 2 Ft.) high, erect, and bearing at the summit a whorl of (usually 3) long-petioled, large, 5- to 7-digitately compound leaves, and an umbel of 5 to 20 small greenish-yellow flowers. The leaflets are from 5 to 15 Cm. (2 to 6 In.) long, ovate to obovate, abruptly short-acuminate, irregularly toothed and thin. The umbel is borne on a slender peduncle 1 to 2 inches in length, and the flowers on slender pedicels about half as long. The fruit is bright-red, about 1 Cm. ($\frac{2}{5}$ In.) broad, flattened and 2-carpelled. The plant grows in rich woods throughout eastern and central North America. It was used to a considerable extent by the North American Indians. Since its collection for exportation, it has been so eagerly sought as to have become exterminated in many districts where it was formerly abundant, and quite scarce elsewhere. A great deal is collected in eastern and central New York, the most of it, perhaps, in and about Minnesota. The tendency toward its extermination, and its high market value, have led to its cultivation, discussed below, and to various devices for preserving the natural supply. In Canada, a fine is imposed for collecting it between January and the first of September. Among the Indians, it is customary to collect the root only after the maturity of the fruit, and to bend down the stem so as to permit of covering the former with earth, before digging the root, thus providing for its propagation. We have been assured by Indian collectors that a large number of such seeds will germinate, and that they have been able to increase their area of collection by this method.

The root should be collected only in the fall, in which case it will retain its plump and handsome appearance after drying. Such roots are also characterized by a much more prominent dark cambium-zone on transverse section. The root is much more highly prized when of a fine light color, which it is far more apt to assume when grown in deep black forest mould. The best root is said to be that collected by the Sioux Indian women, who impart this white appearance by rotating it with water in a partly filled barrel, through which rods are run in a longitudinal direction. In no other way, it is said, can the surface be so thoroughly and safely cleansed.

Fig. 297.

Panax quinquefolius L.

Description.—Ginseng root ranges from 5 to 7 Cm.(2 to 3 In.—occasionally nearly twice this size) in length, and from 1 to 2 Cm. ($\frac{1}{2}$ to 1 In.—occasionally more) in thickness. Its main portion is fusiform and heavily annulated, with a roundish summit, often with a slight terminal projecting point. At the lower end of this straight portion there is a narrower continuation, turned obliquely outward. Very often a rather smaller branch turns outward in the opposite direction, and a very small branch is occasionally borne in the fork between these two. Some small rootlets exist upon the lower portion. The color ranges from a pale yellowish-white to brownish-yellow or, if badly cured, to a brownish color. The structure is fleshy and somewhat elastic or flexible, and it is of a firm, solid consistence, if collected at the proper time and properly cured. The bark is very thick, yellowish-white, radially striate in old roots, and contains brown-red resin-cells. A brown cambium-band separates the bark from the wood, which is strongly and coarsely radiate, with yellowish wood-wedges and whitish medullary rays. The root is of a somewhat aromatic odor and a slightly sweetish and aromatic and strongly mucilaginous taste.

Since the chief value of Ginseng depends upon its favor with the Chinese, and this in turn depends almost wholly upon fanciful considerations, its commercial value is determined in a high degree by its appearance. The roots are valued in accordance with their large size and light color, their plumpness and firm consistence, their unbroken and natural form, and, above all, by the presence in a perfectly developed condition of the three branches above described. A Chinese trader, examining a lot of Ginseng, will eagerly, and by the most cunning devices, seek an opportunity for abstracting from a bale one or more select roots which may represent, in the Chinese market, a money value several times greater than that of the entire remainder of the lot.

Adulteration.—So far as the American market is concerned, there is hardly any other article which can be successfully substituted for entire Ginseng, the only condition in which it is handled to any extent. Adulteration, however, is largely practised, chiefly by the Chinese, by introducing heavy bodies to increase its weight. They are frequently known to bore out the interior through a minute opening and to plug it with lead, afterward closing and concealing the orifice.

Constituents.—The constituents of Ginseng are quite unimportant. There is a large amount of starch and gum, some resin, a very small amount of volatile oil, and the peculiar sweetish body panaquilon ($C_{12}H_{25}O_9$). This occurs as a yellow powder, soluble in ether and alcohol, not in water, colored purple-red with sulphuric acid, and precipitating with water a white amorphous substance which has been called panacon ($C_{11}H_{19}O_4$).

Cultivation.—The cultivation of Ginseng offers a rich field to American agriculture. The most contradictory statements have been made, many of them, on both

sides, from self-interest. Confidence-men, engaged in vending the seeds or roots, have made fabulous statements as inducements for taking up its cultivation, while upon the other hand, those who were already profiting largely from its cultivation have presented discouraging reports, fearing a reduction of their profits through undue competition. The facts are, that the cultivation of Ginseng presents considerable difficulty, owing to the great care and special methods required; and that it is a very slow-growing crop, so that rapid returns can hardly be anticipated. Nevertheless, the percentage returns for the industrious, patient, and painstaking farmer are large, and the demands for a fine article for export are not at all likely to be exceeded by the supply. It is not likely that any cultivation within the present generation will reduce the wholesale price below 2 or 3 dollars per pound. Bulletins of instruction for its cultivation are issued by the U. S. Department of Agriculture. See also *Proc. Amer. Pharm. Assoc.*, 1901, p. 90.

Chinese Ginseng is a larger plant but presents practically the same appearance and habits of growth. Its culture in the United States has never been attempted, but it would appear to be a very promising field for experiment. The drug is also considerably larger than the American, but otherwise its characters are practically the same. The article known as *Red Chinese Ginseng* is made by subjecting the root to a prolonged steaming process by which its weight is reduced about one-half, and it is made to assume a somewhat translucent appearance. Either this, or an unknown species, or possibly both, yield an article known as *Mandarin Ginseng*, select roots of which frequently bring several hundred dollars an ounce.

Six species of Panax are recognized, and the roots of all appear to show a similar composition and properties.

Action and Uses.—This plant possesses little more than the properties of a stomachic. In the United States it is occasionally employed as a masticatory, but in China both varieties are used as a panacea, and particularly for dyspepsia, vomiting, nervous disorders, and sexual impotence.

PANCREATINUM, *U. S.*—Pancreatin.

Pancreatina, Fr. Cod.; *Pancréatine médicinale*, Fr.; *Pankreatin*, G.

A mixture of the enzymes naturally existing in the pancreas of warm-blooded animals, usually obtained from the fresh pancreas of the hog or the ox, and consisting principally of amylopsin, the starch-converting enzyme, myopsin and trypsin, the enzymes that digest albuminoids, and steapsin, the enzyme that digests fat, and capable of converting not less than 25 times its own weight of starch into water-soluble substances, principally sugar, when tested by the process given below.—U. S.

Origin.—The pancreas, or sweetbread, is a large compound racemose gland situated in the epigastric and right and left hypochondrial regions, beneath the stomach. Its right rounded extremity lies next to the duodenum; its left pointed extremity adjoins the spleen. The cells of the gland contain principally zymogens, from which the enzymes are derived. The juice secreted by the pancreas is a clear, colorless, odorless, viscid liquid, when fresh usually not containing more than 1–2 per cent. of matter in solution. While the pancreatic juice obtained from living animals is alkaline, the gland itself, examined soon after removal from recently killed animals, will be found to give an acid reaction. Hydroalcoholic, aqueous, or glycerin solutions prepared from such glands also show an acid reaction toward litmus. The ash from the gland is acid, and contains phosphoric acid.

Preparation.—The U. S. P. gives no process for preparation of pancreatin. The French Codex directs that the pancreas gland, freed as far as possible from foreign matter, is to be minced and placed in water containing a small quantity of chloroform to prevent decomposition. After some time of contact the insoluble residue is expressed, and the resulting liquid filtered and rapidly evaporated in a current of air at a temperature not exceeding 45° C. (113° F.).

Other methods are followed by different manufacturers, such as precipitation with alcohol of an infusion prepared from the pancreas gland with cold water, after removal of fat and connective tissue; or the pancreas, having been freed by mechanical means, as far as possible, from fatty and connective tissue, is minced and passed through a sieve, carefully dried and powdered, and then purified by treatment with solvents for the removal of fat, coloring-matters, etc.

Constituents.—Pancreatin consists of a mixture of at least 4 soluble unorganized ferments, more specifically termed enzymes, and differing from one another in their digestive functions. They are designated respectively as the proteolytic, the amylolytic, or diastasic, the fat-splitting, and the milk-curdling ferment. As yet none of the ferments has been isolated. These enzymes do not exist as such in the cells of the pancreas, but are derived from the zymogens during the digestive process.

Trypsin, the proteolytic ferment, resembles pepsin in its behavior toward albuminoids, and continues in the intestine the work of that ferment begun in the stomach. It differs, however, from pepsin in acting best in a slightly alkaline medium and in splitting the products of peptic digestion, the albumoses and peptones, into simpler bodies, better adapted for absorption as nutritive agents. It is particularly active toward fibrin and muscular tissue, but does not digest coagulated egg-albumin as rapidly as pepsin. It also rapidly digests the casein of milk, with the intermediate formation of metacasein, coagulable by boiling. The presence of a small amount of sodium or potassium bicarbonate in the milk prevents the coagulation of the metacasein. As in the case of pepsin, the action of trypsin is confined to the surface of the substance exposed, the more soluble bodies passing into solution as fast as formed.

While the presence of about 1 per cent. of sodium carbonate or bicarbonate, of the digesting mass, is favorable to increased tryptic activity, the latter also occurs in neutral or even very slightly acid media, showing that the presence of alkali is not absolutely essential. The presence of very small proportions of acid (about 0.03 per cent. of hydrochloric or 0.25 per cent. of acetic acid) is by no means hurtful to the action of trypsin, but an increase to even as little as 0.1 per cent. of hydrochloric acid completely destroys the ferment, and hence its activity ceases at once in a medium having the degree of acidity favorable to peptic action. Trypsin is most active at a temperature between 37° and 40° C. (98.6° and 104° F.). and continues up to 50° C. (122° F.), above which it rapidly diminishes, and ceases altogether at 75° C. (167° F.).

Amylopsin, or pancreatic diastase, closely resembles ptyalin and grain diastase, both in properties and products of conversion, but its action is much more energetic, rapidly liquefying starch-paste and converting starch into dextrin and maltose. Its greatest activity is manifested at a temperature between 30° and 45° C. (86° and 113° F.), and is destroyed at 65° C. (149° F.). The action of amylopsin is not increased by alkalies and is weakened by the presence of acids.

Steapsin, or lipase, has the special function of emulsifying fats and splitting them up into glycerin and free fatty acids. It is rapidly destroyed by strong alcohol and by all acids, except the fatty, being the most delicate of the pancreatin enzymes. Its action on fats can be readily demonstrated by adding a few drops of a neutral solution of pancreatin to a neutral ethereal solution of butter, when upon addition of a little litmus solution the characteristic color-change will take place.

Rennin, or the milk-curdling ferment, is probably identical with that found in the stomach, although according to F. Baden Benger (*J. S. C. I.*, 1887) an alkalinity of 3 to 4 grains of sodium bicarbonate per ounce of milk is favorable to the action of the rennin of the pancreatic juice, whereas the activity of the rennin of the stomach is destroyed by the alkalinity of 1 grain per ounce under similar conditions. The presence of the milk-curdling ferment often fails of detection, on account of the rapid digestion of the casein by the trypsin.

Properties.—The U. S. P. describes pancreatin as a cream-colored, amorphous powder, possessing at most only a faint peculiar odor and a somewhat meat-like taste; slowly soluble in water, and containing not more than 10 per cent. of matter insoluble in that solvent; insoluble in alcohol. It is hygroscopic, and when exposed to the air for some time loses its value; hence it should be preserved in well-stoppered bottles. Dilution with sugar of milk seems to retard deterioration, and saccharated pancreatin has been found to retain its peptonizing value far better than the pure article. Dissolved in water, pancreatin yields a clear, pale-yellowish liquid, which is precipitated by heat, mineral acids, metallic salts, absolute glycerin, strong alcohol, and tannic acid, but not by a saturated solution of sodium chloride; in this latter respect it differs markedly from pepsin. It is not possible to prepare a solution of pancreatin which will retain the activity of all the enzymes present: this is perhaps due to the destructive effect of the trypsin upon the other ferments. Pancreatin is incompatible with acid pepsin solutions, and hence they should not be combined. In dry form the ferments of pancreatin are

very stable, but in solution, neutral or alkaline, they undergo change even at ordinary temperature.

Valuation.—The chief value of pancreatin lies undoubtedly in its peptonizing and starch-converting power, and hence both should be determined. The French Codex demands that pancreatin shall dissolve and change into peptone 50 times its weight of fibrin and convert 40 times its weight of potato-starch into sugar, methods of assay being given for both determinations. The U. S. P. gives the following methods for valuation of the amylolytic and proteolytic powers of pancreatin.

Assay of Pancreatin.—Dry powdered starch, 7.5 Gm., distilled water 120 Cc., pancreatin, 0.3 Gm., iodine test-solution, consisting of 2 drops of one-tenth normal iodine solution dissolved in 60 Cc. of distilled water. Place the starch in a flask, add the 120 Cc. of distilled water, and boil until a transparent mixture results. Cool the resulting paste to 40.5° C. (105° F.), and add to it the pancreatin previously dissolved in about 10 Cc. of water at 40.5° C. (105° F.). Shake well and maintain the temperature at 40.5° C. (105° F.) for 5 minutes, when all the starch should be converted into water-soluble substances, resulting in a thin liquid. To 2 drops of this thin liquid, kept at 40.5° C. (105° F.), add the 60 Cc. of iodine test-solution, when no blue color should result, indicating conversion into sugar, or at most a wine-red color, indicating dextrin and maltose. The appearance of a blue, purple, or any shade of color containing a blue tint condemns the pancreatin as being below standard.—U. S.

If there be added to 100 Cc. of tepid water contained in a flask, 0.28 Gm. of pancreatin and 1.5 Gm of sodium bicarbonate and afterward 400 Cc. of fresh cows' milk previously heated to 38° C. (100.4° F.), and if this mixture be maintained at the same temperature for 30 minutes, the milk should be so completely peptonized that if a small portion of it be transferred to a test-tube and mixed with some nitric acid, no coagulation should occur.—U. S.

Peptonized milk, prepared in the manner just described, or even when the process is allowed to go on to the development of a very distinct bitter taste, should not have an odor of rancidity.

Action and Uses.—Pancreatin contains three digestive ferments, namely, trypsin, which converts proteids into peptones, amylopsin, which converts starches into sugar, and steapsin, a fat-splitting ferment, which aids in the emulsification of fats and decomposes them into glycerin and fatty acids. It is evident, therefore, that pancreatin is a powerful and useful digestive substance, more valuable than is pepsin, since it deals with practically all articles of food. For its activities to be exercised it is essential that the reaction present shall be alkaline. Because of the activities just described pancreatin is used in medicine for the purpose of aiding the digestive functions whenever they are unable, by reason of insufficient or abnormal secretion, to deal with the food which is ingested. In some cases it is given with the food, adding it in liquid or powdered form to the milk or other liquid nutriment if for a child or invalid, or prescribing it in capsule or tablet if the patient is an adult whose digestion is impaired. In whatever manner it is given it is customary to prescribe sodium bicarbonate at the same time.

A large part of the pancreatin at present employed is prepared by Parke, Davis & Co. or Fairchild Brothers and Foster, and is put up either as pure pancreatin in powder with or without sodium bicarbonate, or in the form of tablets, or as peptonizing powders, so prepared that each tablet or powder is of such a size that it will peptonize or digest a given quantity of milk.

The following specific instances in which pancreatin can be employed with advantage may be cited: In cases of gastro-intestinal indigestion in adults and children; in those instances in which bottle-fed babies are unable to digest and assimilate food, and as a consequence pass undigested curds and fat in the stools, for the preparation of nutritive enemata, in the hope that the patient may be nourished by the rectum, when, because of gastro-duodenal disorder, food cannot be taken by the mouth.

For the preparation of food for a bottle-fed child the pancreatin may be added just as the milk is given and the digestive process carried out solely in the stomach, or the milk may be exposed to warmth and the action of the pancreatin for some minutes before it is swallowed.

In cases of indigestion and diarrhœa milk may be prepared as follows: Pour into a clean porcelain-lined saucepan the powder contained in one of the peptonizing tubes, and a teacupful (gill) of cold water; stir well; then add a pint of cold, fresh milk. Heat, with constant stirring, to boiling point. The heat should be so applied that the mixture will boil in 10 minutes. When cool, pour into a clean bottle, cork well, and keep in a cold place. When needed, shake the bottle, and pour out the required portion.

Peptonized beef may be prepared by mincing a quarter of a pound of raw lean beef, and adding to it half a pint of cold water. The meat and water are mixed in a saucepan and cooked over a slow fire, stirring constantly until the mixture has been boiled a few minutes. Pour off the liquid and rub the meat into a paste. Then put it in a clean fruit jar with half a pint of cold water, and add the liquid which was poured off after cooking. Add to the contents of the jar 20 grains of pancreatin and 15 grains of bicarbonate of sodium. Shake thoroughly and put in a warm place, allowing it to stand for three hours with occasional stirring. At the end of this time the contents of the bottle should be brought to the boiling-point quickly, to destroy the pancreatin, and then placed upon ice for preservation. Or, if used immediately, it may be strained and seasoned to taste with salt and pepper, although if not strained it is more nourishing.

Oysters may be peptonized by mincing 6 to 12 large oysters, mixing the minced oysters in a moderate quantity of their own liquid, adding 5 grains of pancreatin and 20 grains of bicarbonate of sodium, and placing this mixture in a water-bath at 100° F. for a period of 20 minutes. After this time, bring the liquid to a boil quickly for the double purpose of cooking the oysters and stopping further digestion.

The digestibility of arrowroot, oatmeal, barley, wheat, or other farinaceous foods can also be increased by mixing with a portion of gruel suitable for one meal a peptonizing tablet or the contents of a peptonizing tube.

When pancreatin is used for the preparation of a nutritive enema the following plan may be employed: Beat up an egg, both the yolk and the white, in a pint of milk. Warm the mixture to the temperature of the body by immersing the bottle which contains it in warm water. Add to the contents of the bottle a peptonizing tablet or the contents of one peptonizing tube. Stir or shake thoroughly, and reimmerse the bottle in the warm water. The enema may be used at once, or if kept on ice it may be given at any time within 24 hours, but it must be warmed before it is used.

PAPAVERACEÆ.—The Poppy Family.

(Including the *Fumariaceæ* or *Fumitory Family.*)

This is a small family, of 28 genera and about 260 species, distributed through temperate and subtropical regions. Except for its ornamental properties, and the use of the fixed oil of poppy seeds as an edible substitute for olive oil, economic interest in the family relates wholly to medicine. So far as known, every member of the family produces alkaloids, and these are in general highly active. Most of these alkaloids will be found discussed under CHELIDONIUM, OPIUM, and SANGUINARIA. A number of minor drugs, considerably used, are described below.

PAPAVER.—This genus contains about 40 species, mostly natives of Europe and adjacent Asia. Besides OPIUM, it yields the 3 following important products:

PAPAVERIS CAPSULÆ, or *Poppy capsules* (Br.), *Fructus Papaveris immaturi* or *Unreife Mohnköpfe* (P. G.), *Papaver* (U. S. 1870), *Mohnkapseln* (G.), *Pavot blanc, Tetes de pavot* (Fr.), *Adormidera* (Sp.), are the nearly ripe capsules of *P. somniferum* L. This, the *Opium poppy*, is elsewhere fully described. The white-flowered and white-seeded form (*P. officinale* Gmel.) alone yields the official capsules (Figs. 294 and 295), but the broad capsules (Fig. 293) are also more or less employed. The former are usually about 6.2 to 7.5 Cm. (2½ to 3 In.) long, exclusive of the stout peduncle, and a little more than half as broad, oval, more or less elongated and narrowed at the base, capped with the 8- to 20-rayed, broad, peltate stigma, from each of the rays of which a line descends upon the smooth, light-brown surface of the capsule, and marks the location of the placentæ, which project inward, forming incomplete partitions. Underneath the margin of the stigma, and between its rays, pores open for the discharge of the very numerous seeds. Occasionally they have a much more elongated form, and occasionally the depressed form shown in Fig. 295. The crushed dried capsules have a very slight narcotic odor, strong in the fresh state, and a bitter taste. Examined microscopically, they exhibit the laticiferous ducts which, when incised, exude opium. Testimony regarding the constituents of Poppy capsules is highly contradictory, and it is probable that these differ with the degree of maturity and other conditions of the capsule. The only constituent of practical importance is about 0.2 per cent. of morphine. Narcotine, narceine, papaverine, rhœadine, probably codeine, and meconic acid have also been reported, and in the waxy coating cerylcerotate ($C_{27}H_{55}.C_{27}H_{53}O_2$), melting at 82.5° C. (180.5° F.), crystallizing in silky scales, and cerylpalmitate ($C_{27}H_{55}.C_{16}H_{31}O_2$), melting at 76° C. (168.8° F.).

Because of the small amount of morphine present in these capsules they may be employed either in syrup or infusion for the purpose of arresting pain and promoting sleep. Their nar-

Fig. 300.

Poppy capsules and seeds: *a*, natural size; *b*, magnified.

White. Black. Depressed.

cotic effect is analogous to that of Opium. A decoction of the capsules may be employed as an anodyne embrocation.

Semen Papaveris, or *Mohnsamen* (P. G.), *Poppy-seed* or *Maw-seed* (E.), *Magsamen* (G.), *Semences* or *Grains de pavot* (Fr.), are the seeds of *P. somniferum* L. Both the White and the Black or Blue poppy-seeds are used, but the White are preferred. The seeds are figured above. They contain an oily albumen, which encloses a curved embryo. They are odorless and possess a bland, oily, sweetish, and very slightly bitterish taste. They contain 55 per cent. of fixed oil (Oleum Papaveris), 23 per cent. of pectin, and about 12 per cent. of protein. Poppy seeds are employed for their oil, which is largely used by artists because of its drying properties. Neither the oil nor the seeds are employed in medicine.

Rhœados Petala, *Red poppy petals* (Br.), or *Flores rhœados*, *Corn poppy* or *Corn rose* (E.), *Klatschrose* or *Klappenrose* (G.), *Coquellicot* or *Pavot rouge* (Fr.), *Amapola* (Sp.), is the petals of *P. Rhœas* L., native of Europe and largely cultivated for ornament. The petals are roundish, obovate, 5 Cm. (2 In.) or more broad, clawed, deep scarlet-red when fresh, dull-purple when dried, bearing a large black spot near the base, very thin, narcotic when fresh, without characteristic odor when dried, mucilaginous and slightly bitter. Although said to contain rhœadine, the constituents are of no medicinal importance, the drug being valued only for its coloring properties, due to 2 deliquescent coloring principles—*rhœadic acid*, which is dark-red, soluble in alcohol and water, but insoluble in ether, and yields brown compounds with alkalies; and *papaveric acid*, which is bright-red, soluble in water and dilute alcohol, and forms violet compounds with alkalies. Red poppy leaves possess little medicinal activity, but are occasionally employed in the form of a syrup for their mild anodyne properties.

Stylophorum (*Yellow* or *Celandine Poppy*) is the plant *Stylophorum diphyllum* (Mx.) Nutt. (*Chelidonium d.*—Mx.), used either fresh or in the dried state. It is a glaucous, yellow-juiced and yellow-flowered perennial of the central United States, very similar to Chelidonium. The stem bears only from 2 to 4 leaves, the 2 upper ones opposite. They are 10 to 25 Cm. (4 to 8 In.) long, petioled, pubescent underneath, at least when young, once or twice pinnatifid, the segments obovate and somewhat crenate or crenately lobed. The yellow flowers are about an inch broad and 2 to 4 together at the summit of the stem. In constituents, properties, and uses, Stylophorum is almost identical with Chelidonium. Schlotterbeck and Watkins have isolated no less than 6 alkaloids from the root (see *Proc. Amer. Pharm. Assoc.*, 1901, 251, and 1902, 404).

Glaucium Glaucium (L.) Karsten (*Chelidonium G.*—L.; *G. flavum* Crantz.; *G. luteum* Scop.), the *Yellow sea* or *Horned poppy*, *Horn poppy*, *Sea celandine*, *Bruise-root*, *Squamatore* (E.), *Hornmohn* (G.), *Pavot cornu* (Fr.), is a peculiar smooth, pale, glaucous-green, succulent biennial of Europe and naturalized in the United States. It grows mostly on sea-beaches and has large, clasping, pinnatifid or sinuate-toothed leaves, yellow, poppy-like flowers, and linear, muricate capsules. It exudes a yellow milk-juice, less acrid than that of celandine. Richard Fischer has carefully examined the root and herbaceous portion of the plant and found them to contain the alkaloids glaucine, fumarine, and chelerythrine (*Arch. d. Pharm.*, 1901, 426–437). *Glaucine* ($C_{21}H_{25}NO_4$) occurs in pale-yellow, well-developed, strongly refractive prisms and tabular crystals, of sharp and bitter taste, soluble in hot water and in alcohol,

ether, and petroleum ether. *Glaucopicrin*, soluble in water and alcohol, but with difficulty in ether, is also said to be present. The drug is used to some extent like *Chelidonium*.

ARGEMONE, the *Mexican*, *Prickly*, *Thorn*, or *Thistle poppy*, *Poppy* or *Flowering thistle*, is a small genus of plants much resembling the last, though the principal veins of the leaves usually terminate in slender prickles. They are plants of the southwestern United States and southward, and have become extensively naturalized in many tropical and subtropical countries. There is much confusion as to the species referred to in the published accounts of the constituents and properties, but it is probable that all are very similar. The plants exude a milky juice, and are bitter and acrid, like Glaucium. The chemical constituents of the plant have been carefully studied by J. O. Schlotterbeck (*Proc. Amer. Pharm. Assoc.*, 1901, p. 247), and it has been shown that Charbonnier's claim, that a trace of morphine is present, is false. The alkaloids found in *Argemone Mexicana* are berberine and fumarine. The important constituent is the fixed oil of the seeds, which exists to the extent of about one-third of their weight. It is light-yellow, of a specific gravity of about 0.919, almost odorless and of bland taste, remaining clear at 6° C. (21.2° F.), and drying slowly and incompletely. It is used as a mild cathartic, very similar to castor oil. Statements regarding the character of the purgative action, and also as to the dose, show great discrepancies. Argemone, in addition to its purgative action, is thought to possess soporific and anodyne properties. It has been recommended in the treatment of flatulent colic. The milky juice obtained from the fresh plant has been employed internally in the treatment of chronic cutaneous eruptions, and locally for the removal of warts and chancroids. The dose of the seeds as a purgative is from 1 to 2 drachms (4–8 Gm.) infused in water.

FIG. 301.

Argemone Mexicana: branchlet (¾ Nat.) and seed (× 5).

ESCHSCHOLTZIA is a small genus of Californian herbs, several of which are known as *California poppy*. Just which species have constituted the basis of experiment and report is uncertain, since the entire group long went under the name *E. Californica* Esch., which species is, in fact, considerably less common and abundant than some of the others. The plants are low, slender, glaucous herbs, with dissected foliage and large yellow flowers, and exuding colored juices, natives of the Pacific coast and far western regions. Fischer (*Proc. Amer. Pharm. Assoc.*, 1901, p. 438), has examined a species supposed to be *E. Californica*, reviewing the work of previous analysts, and reports that it contains fumarine, β and γ homochelidonine, sanguinarine, chelerythrine, and 2 other alkaloids. Morphine, previously said to be present, was not found. Its constituents are thus much like those of Chelidonium.

BOCCONIA is a name which has been employed for two distinct, though closely related, drugs, and these should be distinguished as *Bocconia root* and *Bocconia bark*.

Bocconia root is the root of *Macleya cordata* (Willd.) R. Br. (*Bocconia cordata* Willd.), more generally known by the latter but incorrect name. It is a stout perennial herb, native of Japan, but extensively cultivated for ornament under the name *Tree celandine*. It grows in clumps, to the height of 4 to 6 feet, bears large, petioled, cordate, lobed, glaucous leaves, and the branches terminate in panicles of small white flowers. The juice is yellow or orange. The root is large, irregularly branched, the branches long, of a deep orange-brown, soft and light, of a sternutatory odor, and acrid and bitter taste. Murrill and Schlotterbeck (*Proc. Amer. Pharm. Assoc.*, 1900, p. 128) have determined the presence in it of fumarine, chelerythrine, and β-homochelidonine. Sanguinarine, previously reported, was not found. In smaller amount, alkaloids were found in other parts of the plant.

Bocconia bark, *Llagua-llagua*, or *Hamakari* of the Bolivian natives, is the bark of several species of *Bocconia*, shrubs or small trees of tropical America. Although none are commercially important, all are powerfully active and poisonous. The living plants exude milk-juices, varying from orange to blood-red in color, and excessively acrid. The dried bark varies from 2 to 6 Mm. ($\frac{1}{12}$ to ¼ In.), rarely more, in thickness, when young is smooth and silvery, with black specks, on the outer surface, becoming with age grayish-red-brown and roughly fissured. The inner surface is of a deep brownish-red. It cuts like cheese, and the cut surface is waxy-lustrous and of a deep-red color. The texture is laminated and somewhat shreddy, and the bark is light and soft, and it contains numerous laticiferous ducts, resin-cells, and oil-globules. It has a narcotic, pungent, and very sternutatory odor, and a

bitter and very acrid taste. Several alkaloids have been found. They have not been carefully identified and are probably mostly those of Bocconia root. The action of the drug is much like that of Sanguinaria.

Fumariaceæ.

The drugs which remain to be considered belong to the Fumariaceæ division of the Papaveraceæ.

Fumaria (*Fumitory, Beggary, Wax-dolls*, E.; *Feldraute, Erdrauch*, G.; *Fumeterre*, Fr.; *Hiel de tierra, Pajarilla*, Sp.) is the herbage of *Fumaria officinalis* L., a low, pale-green, smooth, and glaucous annual, native of Europe and somewhat naturalized in North America. The leaves are finely dissected, the ultimate segments obovate-oblong to spatulate and acutish. The pale-red flowers, varying to purple or crimson, are in racemes, and bear a basal spur on one side. The odor is narcotic, the taste bitter and somewhat acrid. Besides ordinary herbal constituents, fumitory yields the alkaloid *fumarine* ($C_{21}H_{19}NO_4$, subsequently called "protopine," when discovered in opium) and *fumaric acid* [$C_2H_2(COOH)_2$]. Fumarine occurs in colorless monoclinic bitter crystals, soluble in alcohol and chloroform, slightly so in water, and insoluble in ether. It is closely allied to corydaline. Fumaric acid forms colorless prisms or stellate scales, and is soluble in alcohol and ether, somewhat soluble in cold water, and more so in hot water. Its salts are mostly soluble in water, and insoluble in absolute ether.

There are about 40 species of *Fumaria*, 8 or 10 of which are medicinally employed. The name Fumaria, as a drug, might almost be extended to include the very similar and closely related plant *Adlumia fungosa* (Ait.) Greene, *Fumaria f.*—Ait., *Adlumia cirrhosa* Raf., the *Climbing Fumitory, Mountain-, Allegheny-*, or *Wood-fringe, Canary-vine* or *Fairy-creeper*, native of eastern and central North America. It is a very slender and weak herb, climbing by its slender petioles. The foliage is very similar to that of Fumaria, but the segments are mostly ovate. The flowers are in axillary, drooping cymes, and are purplish and 2-spurred at the base. The constituents are apparently very much like those of *Fumaria*. Fumitory was formerly recommended in the treatment of chronic cutaneous affections, in hepatic obstructions, and scorbutic diseases. The expressed juice may be given in doses of from 1 to 2 fluidounces (30–59 Cc.) during the day.

Corydalis is a genus of nearly 100 species, distributed through the north-temperate zone, several of which have been employed in medicine. As commonly understood in medicine, the name Corydalis applies to the tubers of *Bicuculla Canadensis* (Goldie) Millsp. (*Corydalis C.*—Goldie; *Diclytra C.*—DC.; *Dicentra C.*—Walp., also one of the plants often called "*Corydalis formosa*"), the *Turkey* or *Squirrel corn* or *Turkey pea, Wild hyacinth* or *Stagger weed*, a plant of eastern and central North America. It is a low, delicate, pale, smooth, and glaucous perennial herb, with dissected leaves, the segments linear-oblong, and produces several scapes, each bearing about 4 greenish-white, purple-tinged flowers, its 2 short and rounded spurs giving it a heart-shaped appearance. The thin subterranean shoots bear small tubers, which are collected. They are depressed-globose, 6 to 10 Mm. ($\frac{1}{4}$ to $\frac{3}{8}$ In.) thick, of a tawny-yellow color, nearly smooth, with a scar on each of the depressed sides, internally yellow or yellowish-white. The tuber breaks with a somewhat horny or slightly mealy fracture, is nearly inodorous, and has a bitterish and rather persistent taste.

Corydalis contains corydaline, fumaric acid, yellow bitter extractive, acrid resin, and starch. *Corydaline* ($C_{18}H_{19}NO_4$) crystallizes in bitter prisms or needles, which become yellow on exposure. It is soluble in alcohol, ether, chloroform, and fixed and volatile oils, and insoluble in water. Besides this, *Capnoides tuberosum* (DC.) Lyons (*Corydalis t.*—DC.; *C. cava* Schweig.; *C. bulbosa* Pers.), yields *corycavine* ($C_{23}H_{23}NO_5$) in small matted needles, and insoluble in ordinary solvents, crystalline *bulbocapnine* ($C_{34}H_{36}N_2O_7$), the most abundant alkaloid in the plant, and *corydine*, an alkaloid insoluble in water and readily soluble in alcohol and ether. *C. nobilis* Pers. yields *corydalnobiline* ($C_{22}H_{25}NO_5$).

Fischer has examined *B. cucullaria* (L.) Miller (*Dicentra C.* Torrey, etc.), the *Dutchman's, Little boy's*, or *Kitten's breeches, Breeches flower, Soldier's cap, White ear-drops*, a very similar plant, and finds it to contain fumarine and 2 other alkaloids. The same author was in 1902 engaged in reviewing the literature of the constituents of the preceding species.

The genus contains about 15 species, and several others, besides those named above, are employed, and have been found to contain similar alkaloids. This plant is said to be tonic and antisyphilitic. It is occasionally employed in the treatment of chronic cutaneous affections, syphilis, and scrofula. The dose is from 15 to 30 grains (0.97–1.94 Gm.).

PAPAYA. PAPAW. CARICA.

The juice of the fruit of *Carica Papaya* L. (*Papaya Carica* Gærtn.; *P. vulgaris* DC.—Fam. *Papayaceæ*).

Origin.—The *Papaw, Melon-tree, Mamœiro, Melonenbaum* or *Papaybaum*, is a dicœcious or polygamous tree, of very peculiar appearance and habit, native of tropical

America, where it is everywhere cultivated for its edible fruit. It is also cultivated, and has escaped, in other tropical countries. Its large, fusiform root, as well as its trunk, is rather soft and fleshy. It sometimes attains a height of 30 or 40 feet, although under cultivation usually less than half as tall. In the wild state it is occasionally much taller. It is surmounted by an umbrella-shaped crown of alternate, very large and very long-stemmed, palmately-lobed leaves, among the bases of which appear the flowers. As the lower leaves fall away, the fruits form, mostly hanging close against the trunk, which continues to elongate, leaf and flower above. All stages of inflorescence and fructification are thus represented at the same time, the lowermost and ripe fruit being often some distance below the leaves, with which it is connected by successively younger fruits. The tree continues to bear fruit for a very few years and then dies. Its cultivation is usually restricted to a few scattered trees in the vicinity of dwellings. Most attempts to cultivate it in large plantations have been unsuccessful, destructive diseases having made their appearance. There is little doubt that these difficulties will eventually be overcome.

The fruit is used in the green state for pickling, and when ripe as a dessert or hand-fruit and for preserving. The ripe fruits vary greatly in size and form, but may be generally described as melon-like in appearance and structure. The entire surface of the cavity is lined with brown-black globular seeds, resembling large bird-shot. All parts of the plant contain a milky juice, this being particularly abundant in the fruit near the time of ripening. In the herbage and green fruit this juice is bitter and more watery. This watery juice is considerably used as a detergent. The juice is always more or less acrid, or even vesicant, and this property is greatest in that of the young fruit. Processes for destroying its acridity weaken the digestive properties of the juice. Although the acrid and digestant principles are probably distinct, it appears not unlikely that the former prepares the substance to be acted upon, as acid prepares albumen for the action of pepsin.

The juice is collected from incisions made in the fruit when nearly full-grown. It flows rather freely for an instant, but the exuding vessels are promptly clogged by coagulation. Fermentation begins almost as soon as the milk is extravasated. For medicinal use, the milk is prepared in various ways. The activity of its enzyme, though checked in the presence of alcohol, is less susceptible to destruction by such antizymotics as glycerin, salicylic acid, etc., than is pepsin, and these have been used as preservatives. The simplest method of preparation is the mere drying of the juice, which should be performed quickly, avoiding a high temperature. This product is apt to possess a disagreeable odor, evidently due to some degree of decomposition. The dried juice of *Carica Papaya* has been marketed under the name of *papoid*. A large amount of the inert substance of Papaya can be removed by extraction with water and precipitation of the filtered extract by alcohol, the precipitate containing most of the digestive ferment. Such a preparation is called *caricin*, *papain*, or *papayotin*. Watt recommends preparing it by adding to the freshly drawn milk twice its bulk of alcohol and draining and drying the insoluble portion, which forms crude papain. By a repetition of the solution and precipitation, its bulk can be somewhat decreased and its color lightened, with a corresponding increase in its proportional activity. The proteolytic activity of papain or papayotin is similar to that of pepsin in producing albumoses and peptones from coagulated albumin or fibrin. Its activity in solution is destroyed at about 82° C. (179.6° F.), but when dried it may be heated to 100° C. (212° F.) for several hours without impairment. Statements differ as to the relative activity of a given quantity of papain and of the amount of Papaya which yielded it, but it appears that the latter possesses rather more activity. It also possesses a higher degree of acridity than papain.

Constituents.—The digestive constituent or constituents of Papaya being enzymic, are, of course, not extractible in the pure state by any method known at present, though they are mostly contained in the papain, papayotin, or caricin referred to above. Of this, the yield from the fresh leaves is about 4 per cent., from the milk-juice upward of 5 per cent. It is amorphous, white or yellowish-white, odorless when pure, and has a faint pepsin-like taste. A great deal of the papain of the market is said to be nearly or quite inert. Other lots are said to be fictitious, consisting of mixtures of one or more other digestants. Single fruits yielded an average of 33 Gm. of milk-juice, which contains, besides papain, 4.5 per cent. of a caoutchouc-like substance, 2 resins, fat, leucin, tyrosin, and malic acid. The very bitter crystalline alkaloid, *carpaine*,

($C_{14}H_{25}NO_2$), has been found to the extent of 0.25 per cent. in dried young leaves, but only 0.07 per cent. in old leaves. The seeds yield a yellow acid resin, which is generally stated as being a substance which gives to the seeds their pungency. There is, however, evidence going to show that this pungency is due to the freeing of a volatile principle from a glucoside similar to sinigrin, through the action of myrosin, similar to what takes place in black mustard. The seeds are used as an anthelmintic, especially against lumbrices.

Action and Uses.—Under the name of "Papayotin," "Papoid," "Caroid," and other trade names, this drug is quite largely employed by some physicians in the treatment of indigestion, since it is capable of transforming proteids into peptones and albumoses by the proteolytic activity already mentioned. This power is slightly active in an acid mixture, as is pepsin, but is greatest in an alkaline mixture, and therefore it is claimed that it is of value both in gastric and intestinal indigestion. It may be said that papaya is slightly inferior to pepsin and greatly inferior to pancreatin in digestive value. Different preparations vary greatly in digestive powers.

The dose is from 1 to 10 grains (0.06–0.60 Gm.), given in solution, tablet, pill, or capsule.

PARAFFINUM, *U. S.*—Paraffin.

Paraffinum durum, Br.; *Paraffinum solidum*, P. G.; *Hard Paraffin*, E.; *Paraffine*, Fr.; *Festes Paraffin, Ceresin, Gereinigtes Erdwachs*, G.

A mixture of solid hydrocarbons, chiefly of the methane series; usually obtained by chilling and pressing the distillates from petroleum having high boiling-points, and purifying the solid press cake so obtained.—U. S.

The Br. P. defines the official article to be a mixture of several of the harder members of the paraffin series of hydrocarbons. Hard paraffin of the P. G. is obtained by purification of the natural deposit known as crude earth-wax.

Origin.—The paraffins are formed under various circumstances from fats and other organic compounds, but are chiefly obtained among the products resulting from the destructive distillation of bituminous shale and other substances. They are a natural constituent in varying proportions of the different kinds of petroleum, and solid paraffins are found native in Austria, Great Britain, the United States (Utah), and some other countries, constituting the minerals known as mineral wax, earth-wax, and ozokerite.

Composition and Characters.—The general formula of the paraffins is the same as that of the lighter coal oils, C_nH_{2n+2}, but in their physical properties they differ from the latter in being at the ordinary temperature either solid, and frequently crystalline, or of a butyraceous consistence or liquid. Those which are liquid at the ordinary temperature are known in commerce as *paraffin oils*, while the name *paraffin* is retained for the solid products. They can be separated from one another only with great difficulty, but it is known that the different members of this homologous series increase in density, viscidity, and in boiling-point, and the solid paraffins also in melting-point and hardness, as the molecular weight increases.

Preparation.—The first step in obtaining hard paraffin is to distil the tarry oil from shale, whereby a residue of coke and asphalt is left. The distillate is treated with sulphuric acid and subsequently with sodium hydroxide for the purpose of removing olefins and phenolic bodies. After washing the product, it is redistilled, and after recovery of lighter hydrocarbons and lubricating oils, yields a thick oil from which paraffin separates on cooling. The crude paraffin is removed, dissolved in petroleum or naphtha, and again allowed to separate by refrigeration and pressure. Finally the resulting wax-like paraffin is melted and decolorized by filtration through animal charcoal.

Properties.—Paraffin occurs as a colorless, more or less translucent mass, crystalline when separating from solution; without odor or taste, and slightly greasy to the touch. Its specific gravity ranges from 0.890 to 0.905 at 25° C. (77° F.), (from 0.820 to 0.940 at 15.5° C. (60° F.), Br.). It is insoluble in water and alcohol; slightly soluble in absolute alcohol; readily soluble in ether, petroleum benzin, benzene, carbon disulphide, volatile oils, and in warm fixed oils. When heated, it melts at from 51.6° to 57.2° C. (125°–135° F.) (54.4° to 57.2° C. (130°–135° F.), Br., 74° to 80° C. (239.2°–250° F.), P. G.), and on stronger heating ignites, burning with a luminous flame and depositing carbon, but leaving no permanent residue. If 0.5 Gm. of paraffin be heated in a dry test-tube with an equal weight of sulphur, the mixture will become black from

the separated carbon, with the evolution of hydrogen sulphide gas. Paraffin is not acted upon or colored by concentrated sulphuric acid or nitric acid in the cold.—U. S. By continued boiling with nitric acid, the higher paraffins yield nitro-compounds and various acids. Chlorine and bromines do not act on paraffins in the dark, but on exposure to sunlight or on application of heat from substitution-products. In distilling paraffin, the heat to which the vapors are exposed influences the melting-point, and consequently the composition; at a red heat naphthalene is produced, and when paraffin is heated for some time in a sealed tube it is split into an olefin and a paraffin of a lower boiling-point. Obtained from the residuum of petroleum distillation, it is about 43° C. (109.4° F.) or somewhat higher; from peat, about 47° C. (116.6° F.); from ozokerite, about 60° C. (140° F.); from Rangoon tar of Burmah, about 62° C. (143.6° F.). The mineral wax of Moldavia, known as *zietrisikite*, melts between 85° and 90° C. (185°–194° F.), and is insoluble in ether.

Tests.—An alcoholic solution of paraffin should not redden blue litmus-paper (U. S., Br., P. G.). If 0.5 Gm. of paraffin be heated and 0.1 Gm. of powdered fuchsin added to the fused mass, the latter should not assume a pink or red color (absence of stearic acid) (U. S.). If 3 Gm. of solid paraffin be added to 3 Cc. of sulphuric acid in a test-tube previously rinsed with warm sulphuric acid, and then heated for 10 minutes in a boiling water-bath, the paraffin should not suffer any change and the acid be at most but slightly colored (P. G.).

Action and Uses.—Hard paraffin is very little used in medicine. Its most common employment is for the sealing of bottles, jars, or boxes containing drugs which it is desirable to protect from the effect of the air. In 1891, Corning, of New York, suggested its employment for the purpose of overcoming minor deformities by injecting it into the subcutaneous tissues. It has been largely used by many surgeons to correct the deformity of saddle-nose and by gynecologists in the treatment of incontinence of urine when the urethra or neck of the bladder needs support. Surgeons have used it to prevent the reunion of nerves after they have been divided, to take the place of a testicle which has been removed, and to diminish the size of a hernial ring. It has even been employed for the purpose of increasing the shapeliness of the female breast. When injected into the subcutaneous tissues it produces no marked effects beyond some swelling and redness, which rapidly disappear under the application of cold. Within a very few minutes after its injection, by means of a syringe attached to a hollow needle, the paraffin becomes hard. It is therefore necessary to rapidly mold it to the desired shape after the injection is made. Its full degree of firmness, however, is not attained until after two or three months have passed, when it often becomes as hard as cartilage and encapsulated. According to some, it remains unchanged in the tissues indefinitely, but others believe that it is gradually absorbed and its place taken by granulation tissue. If the nutrition of the part is not good, or if the paraffin is impure, or, again, if strict antiseptic precautions are not taken, sloughing may take place. J. Chalmers DaCosta quotes Gersuny as employing a solid paraffin mixed with liquid paraffin. The melting-point of the mixture should be about 104° F.—that is to say, the proportions of these two ingredients should be such that the mixture melts at this temperature. It is to be sterilized by boiling, and the syringe is to be warmed in order to prevent the paraffin from solidifying in its barrel. It is also wise to warm the parts to be injected by means of hot compresses. Mixtures which melt at somewhat higher temperatures than 104° F. are dangerous, in that they may produce thrombosis in surrounding blood-vessels, and mixtures which melt below this point may fail to accomplish their purpose by reason of the fact that should the patient be attacked by fever or exposed to heat, the paraffin would melt and lose its shape.

PARAFFINUM MOLLE, *Br.*—Soft Paraffin.

Petrolatum molle, U. S. 1890; *Pétroléine*, Fr. Cod.; *Paraffinum unguinosum; Adeps petrolei.*—*Soft petrolatum, Cosmoline, Vaseline, Paraffin jelly, Soft petroleum ointment*, E.; *Graisse minérale, Pétréoline, Piméléine, Vaseline*, Fr.; *Weiches Paraffin, Paraffinsalbe*, G.

A semisolid mixture containing soft members of the paraffin series of hydrocarbons, usually obtained by purifying the less volatile portions of petroleum.—Br.

Preparation.—Soft paraffin is usually obtained as an intermediate product in the distillation of crude American or Russian petroleum. After removal of the lighter

fractions, benzin, ligroin, and kerosene, all distilling below 330° C. (626° F.), liquid paraffin is collected below 390° C. (734° F.), and the residue then repeatedly treated with sulphuric acid, sodium hydroxide, and animal charcoal, as stated under PARAFFINUM (see above).

Properties and Tests.—Soft paraffin occurs in translucent masses, both white and of yellow color, greasy to the touch, and without unpleasant odor or flavor, even when warmed to 50° C. (122° F.). Its specific gravity at the melting-point, 35.5° to 38.9° C. (96° to 102° F.), or even a little higher, ranges between 0.840 and 0.870. It is insoluble in water, slightly soluble in absolute alcohol, and freely soluble in ether, benzene, and chloroform. Soft paraffin should volatilize without giving off acrid vapors and burn without leaving a residue. The absence of fixed oils, fats, and resins is indicated by the absence of a precipitate upon addition of an excess of acid to the filtrate obtained after boiling soft paraffin with sodium hydroxide solution.

Action and Uses.—Soft paraffin is used as an ointment for the dressing of burns and excoriations, and as an ointment base in the application of drugs to the skin in the treatment of eczema, psoriasis, and scabies. Indeed, it may be employed as an ointment base for almost any purpose, provided that it be borne in mind that in rare cases it will irritate the skin, and more rarely still produce boils or eczematous eruptions. In some instances, these results are probably due to the employment of an impure paraffin. The well-known French ophthalmologist, Galezowski, considers that it is the best excipient for the yellow oxide of mercury and the nitrate of silver, and other mineral substances which are used in the treatment of such eye disorders as keratitis and conjunctivitis. Soft paraffin may also be used as a lubricant in vaginal and rectal examinations.

In its liquid form, which is now placed upon the market under a variety of names, it is employed for the purpose of acting as a vehicle for various drugs, volatile oils, and camphoraceous bodies. Thus, it can be employed as a vehicle for ether, chloroform, benzene, sulphide of carbon, iodine, bromine, phosphorus, eucalyptol, thymol, menthol, myrtol, terpinol, iodoform, and paraldehyde. When holding these substances in solution, it may be used for local applications, or given internally, as it is without any physiological effect in the alimentary canal. When vegetable alkaloids are dissolved in it, such as morphine and cocaine, their rapidity of action is very materially diminished, particularly the latter drug. The hydrochloride of cocaine cannot be used in this way. Rhinologists and laryngologists employ liquid paraffin in its purest forms as a protective after making applications to the mucous membrane of the upper respiratory passages. Under these circumstances its influence is usually negative or at most sedative. But occasionally cases are met with in which when it is applied to the pharynx it produces a sense of dryness or irritation.

PARALDEHYDUM, *U. S., Br., P. G.*—Paraldehyde.

Paraldéhyde, Elaldéhyde, Fr.; *Paraldehyd,* G.

Formula, $C_6H_{12}O_3$. Molecular weight, 131.10.

A polymer of acetaldehyde, CH_3COH. It should be kept in well-stoppered, dark amber-colored bottles, in a cool place.—U. S.

Preparation.—If ordinary (ethyl) aldehyde be treated at normal temperature with small quantities of hydrochloric acid, sulphur dioxide, sodium acetate, or zinc chloride, the temperature of the liquid rises and almost complete conversion into paraldehyde takes place. For the trade it is usually manufactured by conducting gaseous hydrochloric acid into aldehyde at ordinary temperature; the conversion into paraldehyde is known to be complete when the liquor is no longer soluble in an equal volume of water. The crude product is cooled to below 0° C. (32° F.), and the crystalline mass thus obtained is carefully distilled, the process of freezing and distilling being repeated until the whole product finally volatilizes at 124° C. (255.2° F.).

Properties and Tests.—A colorless, transparent liquid, having a strong, characteristic, but not unpleasant or pungent odor, and a burning and cooling taste. It has a specific gravity of 0.990 at 25° C. (77° F.): soluble in 8 volumes of water at 25° C. (77° F.), the solution becoming turbid on being boiled, and in 16.5 parts of boiling water; miscible in all proportions with alcohol, ether, and fixed or volatile oils. When cooled to near 0° C. (32° F.), paraldehyde solidifies to a crystalline mass, which becomes liquid again at 10.5° C. (51° F.). It boils at 123° to 125° C. (253.4°–257° F.), giving off

inflammable vapors. Paraldehyde is neutral, or has a slightly acid reaction. When distilled with a small portion of sulphuric acid, paraldehyde is converted into ordinary aldehyde, boiling at about 21° C. (70° F.). On warming some silver ammonium nitrate test-solution saturated with paraldehyde in a test-tube, a silver mirror will form on standing. On heating some paraldehyde on a water-bath, it should completely volatilize, without leaving any disagreeable odor (absence of impurities derived from fusel oil). 1 Cc. of paraldehyde should form with 10 Cc. of water a clear solution, free from oily drops (absence of amyl alcohol, etc.), and this solution, when acidulated with nitric acid, should not be affected by silver nitrate test-solution (absence of hydrochloric acid) or barium chloride test-solution (absence of sulphuric acid). A mixture of 8 Cc. of paraldehyde and 8 Cc. of alcohol with 1 drop of phenolphthalein test-solution should acquire a pink color upon the addition of 0.5 Cc. of normal potassium hydroxide test-solution (limit of free acid).—U. S.

The P. G. and Br. give the specific gravity at 0.998; the latter requires that no coloration shall take place within 2 hours if paraldehyde be mixed with a solution of potassium or sodium hydroxide (intended to detect the presence of aldehyde). "A mixture of 1 Cc. each of paraldehyde and alcohol should not, after addition of 1 drop of normal alkali solution, show any acid reaction (limit of acid)."—P. G.

Action and Uses.—Paraldehyde is a safe and pure hypnotic, resembling chloral in its effect upon the brain. The sleep produced by moderate doses is natural, comes on speedily, and lasts usually from 5 to 7 hours. The awakening is not attended by headache or weariness. Toxic doses cause coma, muscular relaxation, lowered arterial pressure, and death from paralysis of respiration. The circulatory depression is not so marked as that produced by chloral. In poisonous doses it reduces the hæmoglobin of the blood to methæmoglobin. Eliminated in the urine and breath it imparts its odor to both. It has no influence over pain, and is valueless as a hypnotic when this symptom is the cause of insomnia. In the insomnia accompanying mental or physical strain, delirium tremens, mania, and other forms of insanity of the acute type it has proved useful, and doubtless would be more generally employed were it not for its nauseous taste, the disagreeable odor it imparts to the breath, and its tendency to irritate the stomach. Used for a long time, it may impair digestion and produce irritation of the skin and mucous membranes, particularly those of the thorax and rectum. The dose is from ½ to 2 fluidrachms (2–8 Cc.) well diluted. Brandy, whiskey, or some aromatic may be added to it to mask its taste.

Allied Compounds.—METALDEHYDE, $C_{12}H_{24}O_6$, is obtained by the action of polymerizing agents on common aldehyde at a temperature of 0° C. (32° F.). It is a white crystalline body, insoluble in water, but freely soluble in alcohol and ether. When heated to 112°–115° C. (233.6°–239° F.) it sublimes without melting, but is partially decomposed. It is claimed to possess hypnotic properties (Helbing). *Sulphaldehyde* is formed by the action of hydrogen sulphide on aldehyde. It is said to be an oily liquid of a repulsive odor, solidifying at —8° C. (17.6° F.), and melting again at —2° C. (28.4° F.). Little attention has been bestowed upon it.

ALDEHYDE, *Acetic or ethyl aldehyde, Acetaldehyde* ($CH_3CHO = C_2H_4O$).—This body was noticed, but not isolated, by Scheele (1774), who supposed it to be ether. Liebig (1835) isolated it and determined its relation to alcohol. Aldehyde is formed by the oxidation of alcohol and many of its derivatives; it is found among the products of the dry distillation of wood and sugar and on distilling various protein compounds with manganese dioxide and sulphuric acid. The formation of polymeric modifications of aldehyde was first observed by Liebig. Pure aldehyde is prepared by distilling either of the two following mixtures: 4 parts each of 80 per cent. alcohol and water and 6 parts each of manganese dioxide and sulphuric acid (Liebig), or 3 parts of alcohol, 4 parts of sulphuric acid, mixed and slowly added to 3 parts of potassium dichromate and 12 parts of water contained in a glass retort (Rogers). In both cases the impure distillate is rectified at a temperature of 50° C. (122° F.), and the vapors conducted into anhydrous ether, which is afterward charged with gaseous ammonia, when *aldehydeammonia*, $C_2H_4ONH_3$, crystallizes. The crystals are washed with ether, decomposed by dilute sulphuric acid, and the distillate rectified over calcium chloride. As thus obtained it is a colorless, very mobile liquid, of neutral reaction, and very inflammable; it has a peculiar, rather suffocating odor, and boils at 21° C. (69.8° F.). It is miscible in all proportions with water, alcohol, and ether, and yields with alcoholic potassium hydroxide solution a yellow resin (aldehyde resin), and exposed to the air is converted into acetic acid. Aldehyde separates from ammoniacal silver nitrate solution a metallic mirror, the reaction becoming more delicate in the presence of caustic soda.

PAREIRA, *U. S.*—Pareira.

Pareiræ Radix, Br.; *Pareira brava*, E., G., Fr., Sp.; *Grieswurzul*, G.; *Butua*, Fr., Sp., Port.; *Abutua*, Port.

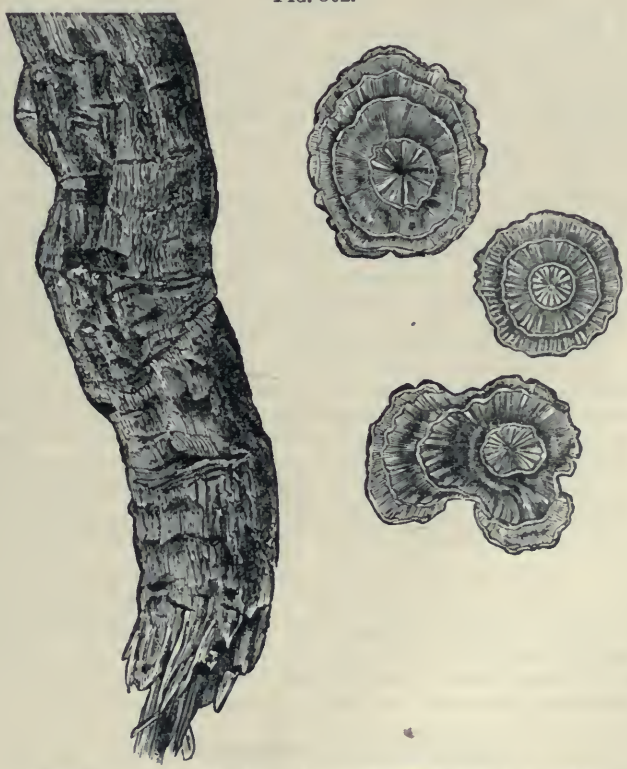
The dried root of *Chondrodendron tomentosum* Ruiz et Pavon (*Cocculus Chondrodendron* DC.—Fam. *Menispermaceæ*).

Pareira is official in but few pharmacopœias. The Portuguese names the roots of *C. platyphyllum* Miers and *Cissampelos Pareira* L.

Origin.—From a tall woody twiner of tropical South America, especially of the upper valley of the Amazon. In its own home it is much confused with the related and similarly growing *Cissampelos Pareira* (see *Substitutes*) and with several species of the related genus *Abuta*, Aubl., which grow as vines, shrubs, or small trees. Pareira is collected by natives, without system, and the market supply is highly irregular and uncertain.

Description.—In subcylindrical, knotty and somewhat tortuous, hard, heavy, and tough pieces of irregular length and 1 to 6 Cm. (about ½ to 2½ In.) thick; externally dark-brown

Fig. 302.



Pareira brava: portion of a root, and transverse sections of the same.

or blackish, longitudinally wrinkled, and bearing transversely elongated protuberances or incompletely annular ridges, as well as constrictions, or occasionally fine fissures; the transverse surfaces drying with several equilaterally concentric circles of interrupted, porous wood-wedges, projecting beyond the markedly retracted intervening tissue of the rather large medullary rays; internally pale brown or yellowish brown, cutting with a waxy luster; inodorous and bitter.

Substitutes and Adulterants.—The pharmacist is quite as likely to receive spurious as genuine Pareira. Although there is much similarity, the differences are ample for distinction. Externally, the rough and nearly black surface of the genuine is closely resembled by only one of the spurious varieties. The originally cut ends show the wood-bundles distinctly, though slightly projecting, while the drug appears soft when cut with a knife and the cut surface has a waxy luster. The commonest substitute is an

unknown related root (or probably a stem) which is gray-brown and smoothish, much lighter in weight, tougher, more fibrous, the rings showing a disposition to separate from one another, the wood-bundles not projecting at the ends, and the drug not cutting with a waxy luster. It contains a very little alkaloid, and yields only about 0.25 per cent. to petroleum ether. The stem of the Pareira vine is somewhat similar to the drug just described. Its pith is distinct. Other substitutes lack the concentric structure. A black substitute, closely resembling the genuine, does not leave a waxy lustrous surface when cut transversely.

Constituents.—Owing to the uncertain identity of the drugs which have been examined under the name of Pareira, most of what has been written regarding its constituents is unreliable. Ringer and Brooke (1892) appear to have had the genuine root when they found 0.819 per cent. of an alkaloid soluble in alcohol and ether, which may or may not have been pelosine (see *Cissampelos*, under *Allied Drugs*). These authors distinguish the genuine by its yield of 8.67 per cent. of fatty products to petroleum ether. Starch, gum, tannin, and phlobaphene were also found. Statements regarding the ash percentage vary from about 11 to 6 per cent., due doubtless to the incineration of different articles.

Pharmaceutical Preparation.—Fluidextract of Pareira, U. S. P.

Action and Uses.—Pareira is useful as a diuretic. In subacute or chronic pyelitis, cystitis, urethritis it does good by exerting a stimulant influence upon the mucous membrane of the entire genito-urinary tract; its action being similar to that of buchu. It is administered in the form of the official fluid extract or of the unofficial infusion [1 ounce to the pint (30–500 Cc.)]; of the former the dose is 1 drachm (4 Cc.), of the latter, 1 ounce (30 Cc.) three times a day.

Allied Drugs.—*Cissampelos* root, because originally, and in many places still, known as Pareira, is often substituted. It is the root of *C. Pareira* L., a woody climber which is credited to tropical regions of both hemispheres, though it is by no means certain that the East Indian root so-called, which is much smaller than the American, is of the same species. This root is 6 to 12 Mm. ($\frac{1}{4}$ to $\frac{1}{2}$ In.) thick, if from India, frequently more than twice as large when from South America or the West Indies, somewhat flattened-cylindraceous, bears a number of broad, shallow grooves and many short transverse fissures, and is of a dark-brown color. The thin bark separates readily. The cross-section shows no concentric structure and is of a yellow-brown color. The fracture is fibrous and tough, the taste bitter, much as in Pareira. It contains 0.5 per cent. of the alkaloid *pelosine*, nearly if not quite identical with beberine and buxine. Pelosine is amorphous, nearly insoluble in water, somewhat soluble in ether and carbon disulphide, but freely soluble in chloroform and acetone, also in alcohol and benzene; its nitrate is sparingly soluble, and its acetate is precipitated by sodium phosphate, by the group reagents for alkaloids, and by potassium iodide, ferrocyanide, ferricyanide, and chromate; the precipitate with phosphomolybdic acid dissolves in ammonia with a blue color.

Yellow Pareira is believed to be the root of *Abuta amara* Aubl., of Brazil, where it is esteemed quite as highly as the official. It is flattened-cylindraceous, very excentric in structure, bright yellow internally and very bitter. It contains beberine or a similar alkaloid, and probably berberine also.

White Pareira (*Butua*, Brazil) is from a related species, *A. rufescens* Aubl. It is whitish or pale yellow internally, with dark medullary rays, and is very starchy.

PASSIFLORA.—Passion-flower.

Passionsblume, G.; *Grandille*, Fr.; *Granadita*, Sp.

The rhizome of *Passiflora incarnata* L. or of *P. lutea* L.

Origin.—These plants are slender, tendril-bearing, climbing, perennial herbs of the southern United States, bearing broad, 3-lobed leaves and usually 5-merous flowers, and having in the throat of the calyx a peculiar fringed crown. The first-named has whitish to flesh-colored or purplish flowers, 3 to 5 Cm. (1 to 2 In.) broad; the second has pale-yellow flowers, only about half as large.

The herbage is sometimes employed as a substitute.

Description.—The rhizome ("root" of commerce) is of irregular length, 3 to 6 Mm. ($\frac{1}{8}$ to $\frac{1}{4}$ In.) thick, cylindrical, finely striate, light-yellowish-brown or slightly greenish, the internodes from 2.5 to 7.5 Cm. (1 to 3 In.) long, the nodes indistinct; hollow, the wood-zone yellowish-green and finely radiate on transverse section, the bark-section purplish; odor slight; taste slight but rather unpleasant and fatty.

Constituents.—Beyond the fact that an alkaloid has been reported, nothing is known of the constituents.

Action and Uses.—Passiflora is little used in medicine. An extract of the rhizome was at one time considered of value as an application to hæmorrhoids, erysipelas, and burns. Internally, the inspissated juice of the leaves has been employed in neuralgic affections in the dose of 1 to 4 drachms (4–16 Gm.).

Allied Products.—The genus contains more than 250 species, mostly of tropical America. Several species are endowed with active properties. *P. quadrangularis* L. yields a delicious fruit, but its root is narcotic, producing spasms, convulsions, a cataleptic condition, and sometimes vomiting. *P. hispida* DC. (*P. marigouja* Per.) and *P. rubra* L., of the West Indies, are also narcotic. *P. fœtida* L. is antispasmodic. *P. laurifolia* L. (*P. tinifolia* Juss.) is anthelmintic. *P. lyrifolia* Tussac is used as a diuretic. Quite a number of species, besides *P. quadrangularis*, as well as those of related genera, yield edible fruits. More than 25 species, besides those named above, are used medicinally or are known to be poisonous.

PELLETIERINÆ TANNAS, *U. S.*—Pelletierine Tannate.

Pelletierinum tannicum; Punicinum tannicum. Punicine tannate, E.; *Tannate de pelletierine*, Fr. Cod.; *Gerbsaures Pelletierin, Gerbsaures Punicin*, G.

Under the official title above given, the Pharmacopœia recognizes a mixture in varying proportions of the tannates of 4 alkaloids obtained from the bark of *Punica Granatum* L.—Fam. *Punicaceæ*. The 4 alkaloids found in pomegranate bark are known both as *pelletierine, isopelletierine, methylpelletierine, pseudopelletierine*, and *punicine, isopunicine, methylpunicine, pseudopunicine*, the former names being preferred, and given in honor of the French chemist, Pelletier.

Preparation.—To obtain the mixture of alkaloids designated as pelletierine tannate, the ground bark is mixed with milk of lime, transferred to a percolator, and exhausted with water, The resulting infusion is shaken out with chloroform, and the chloroformic solution of free alkaloids then shaken out with very dilute sulphuric acid. If to a neutral solution of the mixed sulphates a solution of tannic acid be added, the sparingly soluble tannates will be precipitated and are subsequently dried.

Properties.—Pelletierine tannate (commercial) occurs as a light-yellow, odorless, amorphous powder, possessing an astringent taste and a weak acid reaction. It contains about 7 per cent. of moisture, which may or may not be water of crystallization, and corresponds to 2 molecules of water. Soluble, at 25° C. (77° F.), in 235 parts of water, and in 12.6 parts of alcohol; very soluble in water at 80° C. (176° F.), and in alcohol at 60° C. (140° F.); soluble also at 25° C. (77° F.) in 300 parts of ether, but insoluble in chloroform. Soluble in warm diluted acids. The salt, when dried over sulphuric acid and heated, turns brown at 150° C. (302° F.), softens at about 165° C. (329° F.), and when heated higher decomposes and chars without melting. It leaves no residue on ignition. An aqueous solution of the salt is colored blue-black by ferric chloride test-solution; addition of lead, mercury, or zinc salts causes a white precipitate, as does also ammonia water or caustic alkalies, the precipitate in the latter cases being soluble in excess of the precipitant and forming a yellowish-red solution. Platinic chloride test-solution does not cause precipitation. Aqueous solutions of the salt immediately reduce silver nitrate or gold chloride test-solutions to metallic silver or gold respectively, the former as a black precipitate, and the latter as a thin, purplish mirror on the test-tube. Sulphuric acid when added to pelletierine tannate gives a yellow color, which upon heating turns slowly green and finally purple. Nitric acid produces no color. Sulphuric acid containing a trace of selenous acid produces a light bluish-green color, gradually becoming dark green and developing a pink border.—U. S.

Pelletierine tannate should be kept in well-stoppered, small, dark, amber-colored vials.

The four alkaloids above named may be separated after extraction from the bark and conversion into sulphates, by the following method: Addition of sodium bicarbonate in excess to a solution of the sulphates precipitates methylpelletierine and pseudopelletierine, which are removed by filtration and washing the filtrate with chloroform; after this pelletierine and isopelletierine are precipitated by addition of potassium hydroxide solution and extracted with chloroform. From the latter chloroformic solution the two alkaloids are removed by shaking out with dilute sulphuric acid, and the sulphate solution evaporated to dryness, placed on tissue paper, and exposed to the atmosphere. The isopelletierine sulphate liquefies through absorption of moisture, and is absorbed by the paper, leaving the pelletierine

sulphate as a dry crystalline mass, which is removed, dissolved in water, and made alkaline with potassium hydroxide solution. After extraction of the mixture with chloroform or ether and evaporation of the volatile solvent, the residue from the latter is dried and distilled in a current of hydrogen. Pure pelletierine is a colorless, volatile, oily liquid having a peculiar odor, a specific gravity of 0.988 at 0° C. (32° F.), and boiling at 195° C. (383° F.). It is soluble in 23 parts of cold water, and miscible in all proportions with alcohol, ether, and chloroform. When exposed to the air it undergoes oxidation and gradually assumes a dark color. Pelletierine is a strong base, forming crystallizable salts with acids. The solutions of its salts are precipitated by most alkaloidal reagents, but not by platinic chloride. Pelletierine sulphate, $(C_8H_{15}NO)_2H_2SO_4$, occurs in the form of minute white acicular crystals, which are non-hygroscopic, but readily soluble in water.

The mixture of methylpelletierine and pseudopelletierine mentioned above is dissolved in chloroform and shaken out with dilute sulphuric acid. The resulting solution of sulphates is partially neutralized with alkali and shaken out with chloroform, whereby the methylpelletierine is removed, the pseudopelletierine remaining in solution. Upon evaporation of the chloroformic solution methylpelletierine is obtained, and can be purified by repeated conversions into sulphate and precipitation, until its optical rotation becomes constant. The pseudopelletierine may be recovered from the original still somewhat acid solution by adding alkali in excess and shaking the liberated base out with ether. Upon evaporation of the ethereal solution, the alkaloid is obtained in crystalline form.

Action and Uses.—The employment of this alkaloidal salt in medicine is almost solely as a tæniacide, for which purpose it is probably the most efficient drug known. In large doses it produces symptoms of muscular paralysis, being similar in its action to curare; in other words, it paralyzes peripheral motor nerve plates. Even in full medicinal doses it may bring about a sensation of general muscular relaxation, to which are frequently added giddiness, confusion, and uncertain vision, and occasionally nausea and vomiting. These unpleasant effects may to a certain extent be obviated if the patient remains quiet after taking the drug. While pelletierine is useful as a tæniacide in adults, it is not the remedy of choice in very young children. As usual, before the administration of an anthelmintic, the patient should be starved for at least 12 hours, and in from ½ to 2 hours after the drug is administered an active purge should be given. The dose is from 3 to 8 grains (0.20–0.50 Gm.), commonly given in syrup or capsule.

PEPO, *U. S.*—Pumpkin Seed.

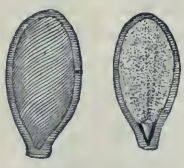
Semen peponis.—*Kuerbissamen* or *Kuerbisskoerner*, *Graumontsamen*, G.; *Semences de potirons* or *de Courge*, Fr.; *Semillas de calabaza*, Sp.; *Pevides de cucurbita*, Port.

The dried ripe seed of *Cucurbita Pepo* L. (Fam. *Cucurbitaceæ*).

Pumpkin seeds are official in a number of pharmacopœias, though the latter do not agree in the botanical names employed.

Origin.—The well-known pumpkin of cultivation, the sole source of the seeds, is of unknown nativity, though it is believed to have originated in North America. The specific identity, or other relations, of several varieties of Pumpkin and Squash are unsettled, although, so far as our definition is concerned, the Squash is supposed to be distinct.

Fig. 303.



Pumpkin seed: entire and longitudinally divided.

Description.—About 2 Cm. (⅘ In.) long, strongly flattened, oval-ovate, somewhat oblique at the bluntly pointed end, rounded at the base, slightly convex on the broad surfaces, with a very slight groove near the little, or not at all, thickened margin, the white or pale-yellow surface nearly smooth or finely granular, frequently covered with fragments of a white membranous tissue; kernel consisting of 2 flat cotyledons and a short conical radicle, devoid of endosperm; nearly inodorous and of a bland, sweet and pleasant, oily taste.

Constituents.—Pumpkin seeds contain 30 per cent. or more of a reddish-yellow fixed oil and a greenish-brown, soft, acrid, and somewhat bitter resin, together with starch, sugar, and other ordinary plant-principles, and an albumin which is easily obtained in well-developed octahedral crystals. The oil has scarcely any odor and is of a mild, sweetish pleasant taste, commencing to congeal at —17° C. (—1.4° F.). Its specific gravity is between 0.91 and 0.915. It consists of glycerides of palmitic, myristic, and oleic acids, which also exist free in the seeds (Kopylow). The resin is generally regarded as the active constituent. Although it has been said that the oil, in doses of

about ½ ounce, possesses the medicinal effect of the seeds, the statement has been denied. If correct, the action is probably due to the presence of some resin in the oil.

Action and Uses.—A very efficient and harmless tæniacide. 1 to 2 ounces (30–60 Gm.) of the seed, thoroughly ground, and made into an electuary with sugar or into an emulsion with water, should be taken on a fasting stomach and followed in from 1 to 2 hours by an active purge. The resin has been given in doses of 15 grains (1 Gm.).

Pumpkin seeds are also distinctly diuretic.

Allied Drugs.—It appears that most of the *Cucurbitaceous* seeds possess the properties of pumpkin seeds. Squash seeds are ordinarily somewhat lighter colored and more spongy, relatively broader and more blunt, and with a more thickened margin. Muskmelon and cucumber seeds are much smaller, relatively narrower and thicker, and with almost no marginal groove. Watermelon seeds, which are sometimes white or whitish, are smaller, flatter, harder, and have a more abrupt and angular edge, usually with minute undulations upon their surfaces.

PEPSINUM, *U. S., Br., P. G.*—Pepsin.

Pepsine, Fr. Cod.; *Pepsine*, Fr.; *Pepsin*, G.

A proteolytic ferment or enzyme obtained from the glandular layer of fresh stomachs of healthy pigs, and capable of digesting not less than 3000 times its own weight of freshly coagulated and disintegrated egg-albumin, when tested by the process given below. If it be desired to use a diluent for reducing pepsin of a higher digestive power to that required by the Pharmacopœia, sugar of milk should be employed for that purpose.—U. S.

An enzyme obtained from the mucous lining of the fresh and healthy stomach of the pig, sheep, or calf. Tested as prescribed it should dissolve 2500 times its weight of hard-boiled white of eggs.—Br.

The French Codex recognizes two varieties of pepsin, designated respectively as Pepsine extractive and Pepsine médicinale. The former is obtained from the stomach of the hog and the rennets of sheep and calves, while the latter is a mixture of the former with starch. No process of preparation is given.

History.—Pepsin was discovered in 1836 by Schwann, and he named it pepsin, from πέψις (digestion). Pepsin is a secretory product of certain glands imbedded in the tissue of the inner coating of the stomach, but has also been found in muscular tissue, urine, brain, and the mucous membrane of the intestine. True or active pepsin probably does not exist at all times in the gastric juice, but is formed by the action of hydrochloric acid and chlorides from a mother substance known as "pepsinogen" as the digestive functions of the stomach may require; in support of this theory we find that glycerin will abstract increased quantities of pepsin from the mucous membrane of the stomach after this has been treated with 0.2 per cent. hydrochloric acid or 1 per cent. sodium chloride solution. The use of pepsin in medicine is mainly due to the efforts of Dr. Corvisart, court physician to the Emperor Napoleon III., but the quality of the commercial article has been vastly improved since that time: to the perseverance and energy of American pharmacists are due the improvements in the mode of manufacturing pepsin and the wonderful increase in digestive power of the commercial article.

Preparation.—A crude pepsin, consisting of the carefully dried mucous membrane of the stomach, is obtained by the following process of Dr. Lionel Beal: The stomach of one of these animals recently killed having been cut open and laid on a board with the inner surface upward, any adhering portions of food, dirt, or other impurity are to be removed and the exposed surface slightly washed with cold water; the cleansed mucous membrane is then to be scraped with a blunt knife or other suitable instrument, and the viscid pulp thus obtained is to be immediately spread over the surface of glass or glazed earthenware and quickly dried at a temperature not exceeding 100° F. The dried residue is to be reduced to powder and preserved in a stoppered bottle. Lamatch's German pepsin is obtained by triturating the mucous membrane of the stomach with clean dry sand, filtering the liquid obtained, and drying this in thin layers at a temperature of 50° C. (104° F.). In the United States two kinds of pepsin are manufactured, known respectively as precipitated pepsin and soluble or scale pepsin; the former is made by the method recommended by E. Scheffer in 1872, and consists in precipitating an acid infusion of clean mucous membrane of hog stomach (prepared cold) by a saturated solution of sodium chloride, redissolving the precipitate in acid water, reprecipitating with salt in order to purify the pepsin, and finally drying at or below 40° C.

(104° F.). (See *Amer. Jour. Pharm.*, 1872.) The process for the manufacture of the so-called scale or peptone pepsins insures an increased yield of product and higher digestive power, but not always the same degree of purity: it consists in subjecting the well-cleaned mucous membranes of animal stomachs, after being thoroughly minced by machinery, to a process of self-digestion in water acidified by hydrochloric acid at a temperature of 38° to 45° C. (100.4°–113° F.), until the whole mass is converted into a uniform transparent glairy fluid. This is allowed to cool and deposit over night after an addition of chloroform or sulphurous acid solution, which prevents putrefaction and in nowise interferes with the activity of the pepsin; the liquid is carefully strained, concentrated in a vacuum apparatus to a syrupy consistence of 8° to 10° B., and spread upon plates of glass, where it is allowed to scale in suitable dust-free rooms. Pepsin thus prepared always contains mucus, peptones, and syntonin, while that prepared by the Scheffer method is contaminated with salt and some inert albuminous matter. In 1891 a process was patented in the United States and in England combining the advantages of the two preceding processes. The essential features are as follows: the well-cleansed and minced mucous membranes are brought to solution by digesting with acidulated water, the solution being clarified after addition of sulphurous acid; the clear liquid is separated from the deposit, and then precipitated by saturating at a higher temperature with sodium sulphate, whereby the pepsin is deposited, while the peptone remains in solution. The precipitated pepsin is dissolved in weak hydrochloric acid and subjected to dialysis, which removes the sodium sulphate and remaining peptones, after which the residual solution is concentrated at a low temperature and dried on plates of glass. The sodium sulphate is not lost in the process, but obtained from the peptone solution by recrystillization. The commercial processes are evolved by slight modifications of the above (see *Pharm. Jour. and Trans.*, 1893, pp. 588–592). A relatively pure pepsin may be obtained by digesting the mucous membranes of the stomach with water acidulated with 5 per cent. of phosphoric acid, filtering, and precipitating the clear filtrate with lime-water, whereby the pepsin is removed mechanically by the phosphate. The precipitate is collected, dissolved in diluted hydrochloric acid, and the pepsin precipitated by means of an ether-alcohol solution of cholesterin. From the latter precipitate the cholesterin is removed by washing it with ether. The residuum, consisting of pepsin, is dried and bottled. Selldén (1873) observed that the mucous membrane is not deprived of pepsin by maceration in acidulated water, but that by digestion at 37° C. (98.6° F.) about double the amount of pepsin is obtained; the mother-liquor from the precipitated pepsin, after having been deprived of salt by dialysis, possesses only very slight digestive properties. That pepsin exists partly in the stomach in an insoluble form has also been demonstrated by Béchamp and by Gautier (1882); the insoluble granules, termed *microzymes*, gradually dissolve in water on digestion.

Properties.—The U. S., British, and German pharmacopœias respectively ascribe the following properties to pepsin: "Lustrous white, pale-yellow or yellowish transparent or translucent scales, or a fine white or cream-colored amorphous powder, free from offensive odor, and having a slightly acid or saline taste. It should not be appreciably hygroscopic. Soluble, or for the most part soluble, in about 50 parts of water with more or less opalescence; more soluble in water acidulated with hydrochloric acid; insoluble in alcohol, ether, and chloroform. Pepsin when in solution is incompatible with alkalies, alkaline earths, or alkaline carbonates, as well as with more than traces of mineral acids. Hydrochloric acid of greater strength than 0.5 per cent. inhibits and rapidly destroys its physiological action. Its solution is precipitated by the salts of many heavy metals, and by tannic or gallic acid. Pepsin and pancreatin in solution are incompatible with one another; if neutral or alkaline, the pancreatin gradually destroys the pepsin, and if acid, the pepsin destroys the pancreatin. On heating a solution of pepsin in acidulated water to 100° C. (212° F.) it becomes milky or yields a light flocculent precipitate, and loses all proteolytic power. In a dry state it can bear this temperature without injury. Pepsin usually has a slightly acid reaction. It may be neutral, but should never be alkaline. The activity of pepsin in solution is destroyed by temperatures exceeding 70° C. (158° F.)."—U. S.

"A light yellowish-brown or white powder, or pale-yellow translucent grains or scales, having a faint odor and a slightly saline taste free from any trace of putrescence, and liable to absorb moisture from the air. Moderately soluble in water, and soluble in about 100 parts of 90 per cent. alcohol."—Br.

"A fine, almost white, slightly hygroscopic powder, having a peculiar bread-like odor

and a sweetish, afterward bitter taste. 1 part forms with 100 parts of water a faintly opalescent solution of very slightly acid reaction."—P. G.

The greater the proportion of peptone present in pepsin the more rapidly does it absorb moisture from the air, and the greater the absence of mucus the less unpleasant will be the odor and the more perfectly clear will be the solution of pepsin in water, especially if the water be acidulated with acetic acid. Except in minute quantities sodium chloride impairs the activity of pepsin; the same is true of alcohol. An aqueous solution of pepsin will decompose in a short time; after addition of hydrochloric acid it remains clear, but gradually loses its effects on albumin. Glycerin, on the other hand, preserves its virtues.

In its proteolytic action pepsin not only dissolves coagulated albumin, but converts it into peptone, which latter should be the true measure of the valuation of pepsin. Its activity was determined (by E. Schütz, *J. C. S.*, 1885; A. Samojloff, *Pflüger's Archiv*, 1901, 85, pp. 86–89) to be proportional to the square root of the amount of the pepsin present (see, also, Bardick and Sayre, *Proc. Am. Pharm. Assoc.*, 1899, p. 310). Pepsin is without action on papain, but the latter destroys pepsin in a neutral or slightly acid medium (V. Harlay, *Jour. Pharm.*, 1900, vi., 11, 466–469).

Tests.—Pepsin exposed on a watch-glass to the air, even in damp weather, should not become sticky in the course of a few hours, showing the absence of an undue amount of peptone. It should form with distilled water an almost clear solution, which is not rendered turbid by the addition of acetic acid, showing the absence of mucus. (Pepsin made by Scheffer's process never yields a clear solution with water, owing to the presence of syntonin or acid albumin.) It should be free from any disagreeable or ammoniacal odor, due to the presence of putrescible matter. A drop of tincture of iodine added to a solution of pepsin should not develop a blue or purplish-red color, showing the absence of starch and dextrin.

Valuation of Pepsin.—The valuation of pepsin by the different pharmacopœias is based upon the proteolytic power or the amount of hard-boiled egg-albumin which the pepsin will dissolve under fixed conditions. The conditions and directions of the various processes must be strictly adhered to to get comparable results for the respective methods.

The following are the official methods of assay of the U. S., British, and German pharmacopœias:

"Mix 9 Cc. of diluted hydrochloric acid with 291 Cc. of distilled water. Dissolve 0.1 Gm. of pepsin in 150 Cc. of the acidulated water. Immerse and keep a fresh egg during 15 minutes in boiling water; remove the pellicle and all of the yolk; rub the white albumin through a clean sieve having 40 meshes to the linear inch. Reject the first portion that passes through the sieve, and place 10 Gm. of the succeeding portion in a wide-mouthed bottle of 100 Cc. capacity. Add 20 Cc. of the acidulated water, and tap the albumin with a glass rod tipped with cork or black rubber tubing until the albumin is completely disintegrated; then rinse the rod with 15 Cc. more of the acidulated water and add 5 Cc. of the pepsin solution. Cork well, invert the vial 3 times, and place in a bath that has previously been regulated to 52° C. (125° F.). Keep it at this temperature for 2½ hours, agitating every 10 minutes by inverting the vial once. After removing from the bath, add 50 Cc. of cold distilled water and pour into a 100 Cc. graduated measuring cylinder. After standing in this for ½ hour, not more than 1 Cc. of undissolved albumin flakes should remain.

"The relative proteolytic power of pepsin stronger or weaker than that just described may be determined by ascertaining by repeated trials the quantity of the above pepsin solution required to digest, under the prescribed conditions, 10 Gm. of boiled and disintegrated egg-albumin. Divide 15,000 by this quantity expressed in Cc. to ascertain how many parts of egg-albumin 1 part of the pepsin will digest."—U. S.

"If 12.5 Gm. of coagulated and firm white of fresh eggs, 125 Cc. of acidulated water, containing about 0.2 per cent. of hydrogen chloride (HCl), and 0.005 Gm. of pepsin be digested together at 40.5° C. (105° F.) for 6 hours, and shaken frequently, the coagulated white of eggs dissolves, leaving only a few small flakes, in an almost clear solution. The white of eggs should be prepared by boiling quite fresh eggs in water for 15 minutes, then immersing them in cold water, and, as soon as sufficiently cool for handling, separating the whites, washing off any fragments of yolk or membrane with water, removing the water with a clean towel, then at once rubbing the whites through a sieve having 12 meshes to a centimeter, and using the product before it has lost moisture. For the acidulated water mix the official hydrochloric acid with water in the proportion of 1 Gm. to 156 Cc.; this will give a solution containing about 0.2 per cent. of hydrogen chloride."—Br.

10 Gm. of fresh hard-boiled (10 min.) egg-albumin, passed through a No. 4 sieve (10 meshes per centimeter), are added to 100 Cc. of water at 50° C. (122° F.), and 0.5 Cc. of hydrochloric acid and 0.1 Gm. of pepsin added thereto. The mixture is kept at 45° C. (113° F.) and agitated frequently during 1 hour, at the end of which time not more than a few whitish-yellow flakes should remain undissolved.—P. G.

The French Codex determines the value of pepsin by allowing it to act on fibrin in acidulated water during 6 hours at a temperature of 50° C. (122° F.), after which the mixture is filtered, and if 20 or 30 drops of nitric acid be then added to the cooled filtrate, no disturbance should occur; the addition of alcohol, on the contrary, causes abundant precipitation. 0.50 Gm. of the medicinal pepsin, or 0.20 Gm. of the extractive pepsin, should digest 10 Gm. of fibrin under the prescribed conditions.

A. H. Allen, in his well-known *Commercial Organic Analysis*, suggests the following method for the valuation of pepsin, which permits of the determination of the peptone and other products of proteolytic action: About 1 Gm. of egg-albumin in scales is powdered and treated in a 100 Cc. flask with 20 Cc. of warm water. When the substance has dissolved, the liquid should be heated in a bath of boiling water to coagulate the albumin, and cooled to a temperature not exceeding 40° C. (104° F.), 0.100 Gm. of the sample of pepsin to be tested should next be added, followed by 25 Cc. of decinormal hydrochloric acid. The liquid is then warmed to 40° C. (104° F.), and kept at that temperature for 3 hours. A volume of $\frac{n}{10}$ sodium carbonate exactly equivalent to the acid previously used is then added, and the liquid heated on the water-bath to 90° C. (194° F.) for 10 minutes. It is then cooled, diluted with water to 100 Cc., and passed through a dry filter. The precipitate will consist of syntonin and any unaltered albumin, while the filtrate contains any albumoses and peptones formed. 50 Cc. measure of the filtered liquid is now saturated in the cold with powdered zinc sulphate (of which about 60 Gm. will be required), allowed to stand with occasional agitation for half an hour, and then filtered. The precipitate is washed with a cold saturated solution of zinc sulphate, the filtrate diluted with water to 250 Cc., acidulated with hydrochloric acid, and treated with excess of bromine water. The nitrogen in the precipitate is determined by the Kjeldahl method and calculated to peptone by multiplying by 6.3. The albumoses may be deduced from the nitrogen found in the precipitate caused by zinc sulphate, after having washed the precipitate with a saturated solution of zinc sulphate.

For application of the method to commercial pepsins, see article of Bardick and Sayre, *Proc. Amer. Pharm. Assoc.*, vol. xlvii., p. 307.

Although the U. S. Pharmacopœia requires of pepsin a digestive power of only 1 to 3000, higher grades are in daily use by physicians, such as 1 to 4000, 1 to 5000, and 1 to 6000. In addition, manufacturers of pepsin are prepared to furnish still purer products, capable of dissolving eight, ten, fifteen, and even twenty thousand times their weight of hard-boiled egg-albumin.

Composition.—Absolutely pure pepsin is unknown; it probably contains the same elements present in other protein compounds. Syntonin has a similar composition, but is insoluble in water and neutral saline solutions; its presence in pepsin made by Scheffer's process was shown by Selldén (1873).

Saccharated Pepsin (*Pepsinum Saccharatum*, U. S., 1890), at one time in favor with physicians, is no longer officially recognized and but rarely used. It was prepared by mixing 1 part of official pepsin with 9 parts of recently dried sugar of milk, the mixture being triturated to a uniform fine powder and preserved in well-stoppered bottles. Containing only 10 per cent. of official pepsin, its digestive power is rather low, although still much higher than the undiluted pepsin of the French and German pharmacopœias.

Pharmaceutical Preparations.—Aromatic Pepsin; Aromatic Solution of Pepsin; Compound Powder of Pepsin; Elixir of Pepsin; Elixir of Pepsin and Bismuth; Elixir of Pepsin, Bismuth, and Strychnine; Glycerite of Pepsin; Solution of Pepsin; Wine of Pepsin.—N. F.

Action and Uses.—Pepsin was introduced into medicine with the idea that it would be of value in those conditions in which the quantity of this ferment of the gastric juice was markedly diminished or absent, but as this rarely occurs, it is doubtful if the administration of pepsin is often needed. The hydrochloric acid that is usually prescribed with it is likely the ingredient of the combination that produces results, for the gastric juice is almost always capable of digesting proteids if it has an acid reaction. This has been proven by acidulating the gastric juice removed from individuals suffering from dyspepsia. The drug has been found of some value in the acute and chronic gastric disorders of infants and young children, and it affords some measure of relief in infantile chronic indigestion with diarrhœa. In the adult it may be used with success in combination with hydrochloric acid, where there is a loss of digestive power either primary or secondary to some other disease. It should never be prescribed in alcoholic menstrua or in combination with alkalies or alkaline salts, as both impair its activity. The acidulated glycerin and water solution is the most stable. It should be administered in moderately large doses, 5 to 30 grains (0.30–2 Gm.).

Saccharated pepsin possesses the same properties and is used for the same purposes as pepsin. Being a weaker preparation, its dose is proportionately larger, and is from 10 to 30 grains (0.6–2 Gm.).

Allied Substances and Products.—Gastric Juice.—As taken from the stomach and filtered from the undigested food, this forms a clear, transparent, limpid liquid of a pale-yellow or brownish color, of a slight peculiar odor, and of a somewhat saline and acidulous taste. It is but slightly heavier than water, and has a strongly acid reaction, which has been attributed to free lactic and hydrochloric acids, to acid phosphates, and to acid hippurates. The gastric juice retains its digestive power for a long time, even after it has become mouldy. Lehmann obtained from it between 0.1 and 0.132 per cent. of free hydrochloric, and between 0.32 and 0.585 per cent. of lactic acid. The latter was observed by Richet (1878) to be identical with *sarcolactic acid* of horseflesh. The total percentage of all solids contained in gastric juice is between 1 and 1.5 per cent., but varies in different animals, and is invariably increased by admixture with saliva. The chlorides amount to nearly 0.5 per cent., among them small quantities of ammonium and calcium chlorides. Phosphates of calcium, magnesium, and iron amount to $\frac{1}{2}$ or $\frac{1}{4}$ per cent., but alkali sulphates and phosphates cannot ordinarily be detected. The gastric juice of the dog and hog have been used in dyspepsia.

Peptones.—Peptones are a product of the digestion of albuminoid substances. In a dry condition they are white amorphous substances and extremely hygroscopic. They are soluble in water. The solution is not coagulated by boiling, nor is a precipitate caused by the addition of acids or potassium ferrocyanide in presence of acetic acid (distinction from albumin), neither is a precipitate caused by solutions of ferric chloride or cupric sulphate, nor by saturating the solution with ammonium sulphate or zinc sulphate (distinction from albumoses). The aqueous solutions of peptone are lævorotatory. Peptones are diffusible through animal membranes and parchment, but much less readily than salts. Neutral solutions of peptone are precipitated by alcohol, tannin, and by various salts of mercury. Acid solutions yield precipitates with potassio-iodide of bismuth, potassio-mercuric iodide, bromine-water, and other group reagents for alkaloids, but these precipitates are soluble in excess of peptone (Tanret, 1881). Brieger (1883) extracted from some peptones by boiling alcohol an amorphous poisonous alkaloid resembling the ptomaïnes in behavior. Peptone is colored yellow by nitric acid, and gives with Millon's reagent, on warming, a red precipitate, and with Fehling's solution a violet-red color.

Peptone is readily assimilated by the intestinal mucous membrane. Poehl (1882) states that peptones may be again converted into albuminoids by the influence of alcohol, various alkali salts, and other agents having much affinity for water. *Peptonized meat* has been recommended as a nutritive medicine. The liquid resulting from the artificial digestion of lean meat is strained, neutralized with sodium bicarbonate, and the filtrate evaporated until it has the density 1.208, when it is stated to contain 50 per cent. of peptone (Petit, 1881), and may be preserved by the addition of glycerin and combined with ferric chloride, mercuric chloride, and other salts. By desiccating its concentrated solution upon oiled plates peptone may be obtained in scales resembling gelatin, which are hygroscopic, but not deliquescent on exposure.

PETROLATUM, *U. S.*—Petrolatum.

Petrolatum spissum, U. S., 1890.

Manufacture.—As already stated under Soft Paraffin, which differs from petrolatum only in its somewhat softer consistence and lower melting-point, petrolatum is obtained as a residue in the fractional distillation of petroleum, which is purified and decolorized as explained under Hard Paraffin. It is a mixture of neutral hydrocarbons, chiefly of the marsh-gas or paraffin series.

Properties and Tests.—Petrolatum, as recognized in the U. S. P., is an unctuous mass, of about the consistence of an ointment, varying in color from yellowish to light amber, slightly fluorescent when yellowish, especially after being melted, transparent in thin layers, completely amorphous, and without odor or taste, or giving off, when heated, a faint petroleum-like odor. When melted and brought to a temperature of 60° C. (142° F.) it has a specific gravity of from 0.820 to 0.850. It melts between 45° and 48° (113° and 118.4° F.). Petrolatum is insoluble in water; scarcely soluble in cold or hot alcohol or cold absolute alcohol; but soluble in boiling absolute alcohol, and readily soluble in ether, carbon disulphide, chloroform, benzin, benzene, oil of turpentine, and fixed oils. When heated on platinum foil to a temperature above its melting-point, it should be completely volatilized without emitting any acrid vapor. Moistened blue litmus-paper should not be reddened in contact with water previously shaken with melted petrolatum. If 2 volumes of concentrated sulphuric acid be added to 1 volume of melted petrolatum in a test-tube placed in hot water, and the contents occasionally agitated during 15 minutes, the acid should not acquire a deeper tint than brown nor lose its transparency (limit of readily carbonizable organic impurities). If 10 Gm. of petrolatum be digested for half an hour with 10 Gm. of sodium hydroxide and 50 Cc. of water, the aqueous layer separated and supersaturated with sulphuric acid, no oily substance should separate (absence of fixed oils or fats of animal or vegetable origin or of resin).—U. S.

A white variety of petrolatum, free from yellow tint, is recognized in the U. S. Pharmacopœia, under the name of PETROLATUM ALBUM. It has the characteristics of petrolatum, with the exception of color, and should respond to all the tests given above.

Action and Uses.—This substance is used as an ointment base instead of lard, etc. It has the advantage over the animal and vegetable fats in remaining free from rancidity, but because it is less readily absorbed than they are it is not a good vehicle for drugs intended to act by absorption through the skin. As a bland, protective application to inflammation of the skin it is of value. Taken into the stomach and intestines it is not absorbed and can, therefore, not be used as a foodstuff; it does, however, produce softening of the stools.

PETROLATUM LIQUIDUM, *U. S.*—Liquid Petrolatum.

Paraffinum liquidum, Br.; P. G.; *Liquid paraffin*, E.; *Paraffine liquide, Huile de paraffine*, Fr.; *Flüssiges Paraffin, Paraffinöl*, G.

A mixture of hydrocarbons, chiefly of the methane series, obtained by distilling off most of the lighter and more volatile portions from petroleum, and purifying the liquid residue.—U. S.

Manufacture.—Liquid petrolatum may be obtained from petroleum after removal of the lighter hydrocarbons, by subjecting the residuary liquid to distillation between 330° and 390° C. (626° and 734° F.), treating the distillate with sulphuric acid and afterward with caustic alkali, and then filtering while hot through animal charcoal. The liquid is cooled to remove solid paraffins, which will crystallize out, and is then again distilled, the fraction distilling above 360° C. (626° F.) being collected.

Properties and Tests.—Liquid petrolatum is a colorless (or very slightly yellowish, U. S.), oily, transparent liquid, without odor or taste. Its specific gravity varies between 0.870 and 0.940 at 25° C. (77° F.), U. S.; from 0.885 to 0.890, Br.; not less than 0.880, P. G. The Br. and P. G. demand that its boiling-point shall not be below 360° C. (680° F.). A mixture of 4 Cc. of liquid petrolatum with 2 Cc. of absolute alcohol, and 2 drops of a clear saturated solution of lead oxide in solution of sodium hydroxide, should remain colorless when kept at 70° C. (158° F.) for 10 minutes (Br.). This latter test depends upon the possible presence of sulphur, which would form sodium sulphide, and as such react with the lead, causing a black coloration due to lead sulphide. In all other respects as regards properties and tests, liquid petrolatum corresponds to those given above under PETROLATUM.

Action and Uses.—This liquid is used as a protective coating, applied by an atomizer, to the respiratory mucous membranes, and as a vehicle for drugs which are to be so applied.

PETROLEUM.—Petroleum.

Oleum petræ.—Rock oil, Coal oil, E.; *Pétrole, Huile minéral*, Fr.; *Steinöl, Bergöl*, G.; *Petroleo*, Sp.

Origin.—Crude petroleum is a liquid mixture of hydrocarbons occurring naturally in the earth and found in immense deposits in certain parts of North America, notably Pennsylvania, Ohio, West Virginia, Texas, California, and Canada, in the Baku district on the west coast of the Caspian Sea, and to a limited extent in most European countries. Occasionally it is found oozing from the ground, frequently mixed with water, but is obtained in largest quantities from wells sunk in the ground to varying depths according to the geological formations from 300 to 2000 feet, whence it is forced up by the natural-gas pressure, or by pumping. Various theories have been advanced to account for its formation both from an inorganic and an organic origin. Thus under the former Byasson (1876) refers it to salt water charged with lime salts coming in contact with metals or their sulphurets; Mendelejeff (1887), to water and metallic carbides; and Ross (1891), to limestone ($CaCO_3$), hydrogen sulphide, and hydrogen peroxide, the gases being of volcanic origin. Its organic origin, however, is more likely as the result of the decomposition and distillation under high pressure of fossil carbonized animal matter. The researches of Höfer, Engler, and Sadtler (*Proc. Amer. Philos. Soc.* 36, 154, pp. 93–102; see also *Zeitschr. angew. Chem.*, 1894, pp. 122–126) give added force to the animal origin of the oil. While primarily produced from animal remains *in situ* in some places, it is likely that in other localities it is the result of distillation from older geological strata.

Properties.—As naturally obtained, petroleum varies in consistence from thin limpidity to the thickness of molassas or tar, and in color from pale yellow to blackish brown, usually of a reddish color by transmitted light, and generally showing a strong greenish fluorescence. Its specific gravity is generally between 0.8 and 0.95, but some varieties slightly exceed water in density. The heavier and dark-colored kinds yield, on rectification, light and limpid oils, and leave a residue consisting of *paraffin* and solid *bitumen*, a variety of which is found native as *asphaltum*. The latter is black, glossy, and brittle, while the bituminous residues from coal-oil distillation are less glossy and scarcely brittle at the ordinary temperature. The solid as well as the liquid fractions of petroleum are inflammable and burn with a bright sooty flame; the vapors of the more volatile kinds, mixed with atmospheric air, are highly explosive.

Barbadoes petroleum and *Seneca oil* were formerly employed for medical purposes. The former is characterized as a dark-colored, almost black, viscid liquid, specific gravity 0.73–0.878, and having a bituminous taste and odor. *Seneca oil*, obtained from the shores of Seneca Lake, was a lighter colored, thinner, and less disagreeable smelling oil.

Constituents.—Petroleum consists of a large number of hydrocarbons, belonging to two homologous series—namely, that of *marsh-gas*, of the general formula C_nH_{2n-2}, and of *olefiant gas* (olefin or ethylene series), having the formula, C_nH_{2n}. On treating petroleum with strong sulphuric acid the olefins, coloring-matter, and some other constituents are removed, and the hydrocarbons of the paraffin series left. The hydrocarbons of both series exist also in isomeric modifications which differ from the normal compounds in volatility and some other properties. Those containing C_4 and less are gases at the ordinary temperatures; the relation of the others is shown by the following table:

	Normal.	Iso.		Normal.	Iso.
Pentane, C_5H_{12}, boils at	38° C.	30° C.	Pentene, C_5H_{10}, boils at	37° C.	35° C.
Hexane, C_6H_{14}, "	70° C.	62° C.	Hexene, C_6H_{12}, "	70° C.	65° C.
Heptane, C_7H_{16}, "	98° C.	90° C.	Heptene, C_7H_{14} "	100° C.	——
Octane, C_8H_{18}, "	124° C.	118° C.	Octene, C_8H_{16}, "	125° C.	——

These compounds are to some extent separated by fractional distillation. The portion boiling below 50° C. (122° F.), being collected by itself, constitutes *naphtha* or *gasolene*, and consists almost exclusively of pentane and pentene; but if the vapors are well refrigerated the product contains also *butane*, C_4H_{10}, boiling at 1° C. (33.8° F.), and constitutes *rhigolene*, which requires to be kept in strong and well-corked bottles and in a cool place, since it evaporates rapidly at the common temperature. The naphtha freed from the low-boiling hydrocarbons is commonly known as *benzin* or *petroleum benzin* (see page 290); its specific gravity is about 0.67. The portion boiling at a higher temperature is separately collected and furnishes *kerosene*, *photogene*, or *coal oil*, which is largely employed for illuminating purposes; its safety for that use depends upon the absence of the low-boiling hydrocarbons. At a still higher temperature paraffin oils, paraffin jelly, and paraffin wax pass over, and the residue left in the still at a temperature of about 400° C. (752° F.) constitutes the ordinary *asphaltum* or *bitumen*. Heptane was ascertained by Thorpe (1879) to be a constituent of the volatile oil of *Pinus Sabiana*. Sulphur to the amount of 1 or 2 per cent. is a constituent of the Beaumont, Texas, petroleum, and is also found to the extent of 0.5 to 0.6 per cent. in the Lima, Ohio, crude oil.

OLEUM PETRÆ ITALICUM, S. PETROLEUM CRUDUM.—Yellowish or reddish, limpid, iridescent, of a peculiar bituminous odor, soluble in fixed and volatile oils, in ether and absolute alcohol, with difficulty soluble in alcohol; specific gravity 0.75 to 0.85.

Crude petroleum varies considerably in composition according to the locality from which it is derived. The Canadian, Ohio (Lima district), and Texas (Beaumont) oils are characterized by variable percentages of sulphur, about 0.4 to 0.5 per cent. in the two former and 1 to 2.5 per cent. in the Beaumont oils. In the Lima oils Mabery (*Amer. Chem. Jour.*, 1891) has identified methyl, ethyl, normal propyl, iso- and normal butyl, pentyl, and hexyl sulphides. For the composition of California, Ohio, and Texas petroleum see articles by C. F. Mabery (*Amer. Chem. Jour.*, *25* [4], pp. 253–284; *ibid.*, *13*, pp. 232–243; *Jour. Amer. Chem. Soc.*, *23*, pp. 264–367).

The total yield of crude petroleum in the U. S. for the year 1901 amounted to 69,389,194 barrels, and for 1902 was estimated at not less than 83,000,000 barrels.

Uses.—In the dose of 15 to 30 minims (1–2 Cc.) it has been used internally as an intestinal antiseptic.

PHENACETINUM, *Br., P. G.*—Phenacetin.

Acetphenetidinum, U. S.; *Acet-Phénétidine*, Fr. Cod.
For full description, see ACETPHENETIDINUM, page 11.

PHENOL, *U. S.*—Phenol.

Acidum carbolicum, Br., P. G. (U. S. 1890); *Phénol, Acide carbolique, Acide phénique*, Fr. Cod.; *Acidum phenicum s. phenylicum.—Carbolic acid, Phenic acid, Phenic alcohol, Benzophenol*, E.; *Karbolsäure, Phenylsäure*, G.; *Fenolo cristallizzato*, F. It.; *Acido fenico (carbolico)*, It., Sp.

Formula, C_6H_5OH. Molecular weight, 93.34.

Hydroxybenzene, obtained either from coal-tar by fractional distillation and subsequent purification, or made synthetically, containing, when assayed by the process given below, not less than 96 per cent. of absolute phenol. It should be kept in dark amber-colored, well-stoppered bottles.—U. S.

Although the name *carbolic acid*, by which this compound was officially recognized for many years, has been dropped from the Pharmacopœia, it will no doubt continue to be used commercially for some time to come.

Origin.—Phenol occurs in castoreum, in the urine of man and of herbivorous animals, and in the products of the dry distillation of various organic substances, such as resins, bones, wood, and more especially coal. It is from the latter source that it is obtained in the arts. It was obtained first by Runge (1834), and in a purer condition by Laurent (1840), who ascertained its composition and chemical behavior.

Preparation.—That portion of coal-tar collected by distillation between 100° and 250° C. (212° and 482° F.) is known as *light oil*. It has a specific gravity of 0.94–0.99, and contains from 4 to 10 per cent. of acid. This fraction is agitated with a 10 per cent. sodium hydroxide solution (a stronger solution is not desirable, since it would dissolve naphthalene and other impurities contained in the oil), and upon standing separates into two layers, the lower being a solution of sodium-phenol, while the upper consists of the extracted oil. The lower layer is carefully drawn off and treated with hydrochloric or sulphuric acid in such quantity as has been ascertained (by a previous test) to be sufficient for exact decomposition. In some cases the sodium-phenol solution for the purpose of purification is treated first with about one-eighth of the necessary quantity of acid, whereby homologous phenols are separated, and after the removal of these the solution is decomposed completely by acid. The impure phenol thus liberated rises as an oily layer to the surface, which, after removal, is washed by agitation with concentrated solution of common salt, freed from water by means of calcium chloride, and then distilled between 180° and 190° C. (356° and 374° F.). Upon exposure in cool places the distilled phenol congeals to a crystalline mass, which, after being freed from adhering liquid, is again distilled, that portion coming over below 185° C. (365° F.) being carefully collected and crystallized. Sometimes the phenol before final distillation is treated with potassium dichromate and sulphuric acid. In order to obtain phenol in colorless loose crystals, it may be recrystallized from boiling petroleum benzin.

While the above method is the one now generally followed, some manufacturers in Europe extract phenol from a smaller fraction of the coal-tar distillate, known as *heavy oil*, and collected between 160° and 220° C. (320° and 428° F.), the treatment being practically identical with that given above.

The bulk of phenol is manufactured in Europe, particularly in England, little of the crystallized acid being made in this country.

Absolutely pure phenol was obtained by Church (1871) from the nearly pure commercial product by treating it with a quantity of water (about 20 parts) insufficient to dissolve it completely, removing the undissolved portion, and saturating the clear aqueous solution with pure table-salt, when the phenol separated as an oily layer, requiring distillation over quicklime to obtain it crystallized. The portion passing over up to 185° C. (365° F.) has, at ordinary temperatures, merely a very faint aromatic odor.

SYNTHETIC PHENOL.—Since 1888 considerable quantities of synthetic phenol have been placed upon the market. This is prepared directly from benzene (benzol) by first treating it with fuming sulphuric acid and moderately warming the mixture, whereby benzene-sulphonic acid is produced: $C_6H_6 + H_2SO_4 = C_6H_5SO_2OH + H_2O$. The acid thus formed is neutralized with potassium carbonate, yielding potassium benzene-

sulphonate, and this compound then fused with a large excess of potassium hydroxide, whereby potassium sulphite and potassium-phenol are formed: $2(C_6H_5SO_2OK) + 4KOH = 2H_2O + 2K_2SO_3 + 2C_6H_5OK$. The potassium-phenol finally is treated in solution with hydrochloric acid, in order to liberate the phenol or carbolic acid, which is purified further by distillation: $C_6H_5OK + HCl = C_6H_5OH + KCl$. The advantages of the synthetic method are chiefly the absence of homologous products (cresol, xyleue, etc.), as the benzene can be procured of great purity by means of crystallization.

Properties.—Pure phenol has a faint aromatic odor, is colorless, crystallizes in needles, and does not absorb moisture from the atmosphere (Moss, 1875). Usually, however, it retains a minute quantity of water, by which it becomes deliquescent; with a little more water it forms an oily liquid, which crystallizes at a lower temperature; and if traces of the tar-products are present, it acquires a reddish color on exposure, and deliquesces to a brown-colored oil. This peculiar red color has been investigated by E. Fabini, and, according to that author, it is due to the formation of an organic coloring-matter, named by him *phenerythen*, caused by the presence of minute quantities of metal (probably copper) in the phenol. Hydrogen peroxide, metal, and ammonia must be present to produce the color; ammonium-phenol, being formed by absorption of ammonia from the air, reacts with the metal present, forming a metal carbolate, and this in turn is acted on by hydrogen peroxide, yielding the characteristic red color. The odor is modified by the presence of a little cresol. Phenol is insoluble in petroleum benzin, but freely soluble in alcohol, ether, glycerin, the volatile and fatty oils, in glacial acetic acid, caustic alkalies, carbon disulphide, and chloroform, the solutions in the last two liquids separating all the water present, the amount of which may thus be determined. Phenol dissolves at 15° C. (59° F.) in about 15 parts of water. It is soluble in 19.6 parts of water at 25° C. (77° F.), the solubility varying according to the degree of hydration of the phenol (U. S.). The solution is perfectly transparent, and has only a faint action upon blue litmus-paper. Phenol is less soluble in many saline solutions than in water; it yields, with a limited amount of concentrated solutions of the fixed alkalies, a crystalline mass, which, after being pressed, consists merely of phenol, and is almost free from potassa (Calvert, 1865). The fusing-point of crystallized phenol is influenced by the amount of water with which it is combined; the U. S. P. does not specify the melting-point, but demands that the congealing- or crystallizing-point shall not be below 40° C. (104° F.), while the melting-point is placed not lower than 38.8° C. (102° F.) (Br.). Phenol melting at about 40° C. (104° F.) (F. It., P. A.), between 40° and 42° C. (104° and 107° F.) (P. G.), represents almost absolute acid. The boiling-point of phenol is given at not higher than 188° C. (370.4° F.) (U. S.), not higher than 182° C. (359° F.) (Br.), about 180° C. (356° F.) (F. It., P. A.), between 178° and 182° C. (352.4° and 359° F.) (P. G.). It should be borne in mind that cresols which may be present have a higher boiling-point, that phenol contains variable proportions of water, and that a lower boiling-point or a higher melting-point indicates a purer and less hydrated phenol. Phenol volatilizes slowly at ordinary temperatures, rapidly at the temperature of boiling water, without residue. "When gently heated, phenol melts, forming a highly refractive liquid. It is also liquefied by the addition of about 8 per cent. of water. If the phenol be liquefied by a gentle heat, and then slowly cooled with constant stirring until it is partly recrystallized, the semi-liquid mass should have a temperature (remaining stationary for a short time) not lower than 40° C. (104° F.). On adding to 10 Cc. of an aqueous 1 per cent. solution of phenol 1 drop of ferric chloride test-solution, the liquid acquires a violet-blue color, which is permanent."—U. S. It has the specific gravity 1.060–1.066 at the melting-point, separates nitrocellulose in a gelatinous form from collodion, coagulates albumin, and has a caustic, acrid taste, but when largely diluted with water tastes sweetish and smoky. The vapor of phenol is inflammable.

A piece of pine wood dipped into an alkaline solution of phenol, and afterward into hydrochloric acid, assumes in the course of half an hour a deep-blue color. According to Tiemann and Haarmann, this color is a characteristic reaction of coniferin. The solution of phenol has no effect on polarized light. The concentrated alcoholic solution yields with ferric chloride a brown liquid, which on the addition of much water remains transparent and assumes a beautiful and permanent violet-blue color (Flückiger, 1872). When heated in sealed tubes with ammonia it yields but small quantities of phenylamine (aniline, $C_6H_5NH_2$). Fused with excess of potassium hydroxide, oxybenzoic and salicylic

acids are found among the products of decomposition. It is oxidized by potassium permanganate, yielding carbon dioxide and oxalic acid. Concentrated sulphuric acid converts it into phenolsulphonic (sulphocarbolic) acid, $C_6H_5OHSO_3$. Under the influence of nitric acid several substitution-products are formed, the most important of which is picric acid. Substitution-compounds are formed likewise with chlorine, iodine, and bromine. The last-named element, acting either in the form of vapor or as bromine-water upon an aqueous solution of phenol, produces a flocculent white precipitate of tribromophenol, $C_6H_2Br_3OH$, which crystallizes from alcohol in silky needles, melting at 98° C. (208.4° F.). This reaction is so delicate that a solution of phenol in 50,000 parts of water is still rendered turbid; it should, however, be remembered that alkaloids, cresols, and various other compounds are precipitated likewise by bromine-water.

Tests.—The purity of phenol is recognized by the properties described above, by the absence of all reaction upon red litmus-paper, and by the non-production of a dark color or precipitate in the aqueous solution by hydrogen sulphide, proving the absence of metallic compounds. The absence of cresol (cresylic acid) may be determined by mixing 1 volume of glycerin with 1 volume of cold liquefied phenol (rendered liquid by the addition of 8 (10, Br.) per cent. of water); a clear liquid should result, which is not rendered turbid by the addition of 3 volumes of water (U. S.).

The valuation of phenol is prescribed by the U. S. P. to be made with tenth-normal bromine solution (Koppeschaar's Solution), each Cc. of which corresponds to 0.001556 Gm. of absolute phenol. The solution is not, strictly speaking, a tenth-normal bromine solution, which would be very unstable, but is a solution of sodium bromate and bromide of such strength that upon addition of hydrochloric acid the quantity of bromine liberated shall correspond to that required for a tenth-normal solution, namely, 0.007936 Gm. per Cc. The test depends upon the formation of tribromophenol, and is made by adding to an aqueous solution of phenol a slight excess of the bromine solution, adding hydrochloric acid and potassium iodide, and, finally, titrating the iodine liberated by the excess of bromine by means of tenth-normal sodium thiosulphate solution. The reactions involved in this test are as follows: 1. The liberation of bromine by means of hydrochloric acid; thus, $NaBrO_3 + 5NaBr + 6HCl = Br_6 + 6NaCl + 3H_2O$. 2. The precipitation of tribromophenol; thus, $C_6H_5OH + Br_6 = C_6H_2Br_3OH + 3HBr$. 3. The liberation of iodine from the potassium iodide added; thus, $2KI + Br_2 = I_2 + 2KBr$. 4. The decoloration of the iodine solution formed; thus, $2Na_2S_2O_3 + I_2 = 2NaI + Na_2S_4O_6$. The second equation shows that 93.34 parts of absolute phenol require 476.16 parts of bromine for complete precipitation. Having found the excess of bromine solution, the calculation for percentage of absolute acid in the sample is easily made; for instance, if 0.05 Gm. of carbolic acid should require exactly 30 Cc. of tenth-normal bromine solution for precipitation, the sample would be said to contain 93.36 per cent. of absolute phenol. The U. S. P. demands at least 96 per cent. as ascertained by the following method: Dissolve 1.556 Gm. of the phenol to be valued in a sufficient quantity of water to make 1000 Cc. Transfer 25 Cc. of this solution (containing 0.0389 Gm. of the phenol) to a glass-stoppered bottle having the capacity of about 200 Cc., and add 30 Cc. of tenth-normal bromine solution (which is 5 Cc. more than would be required if the phenol in the solution were absolutely pure, the excess being added to promote the formation and separation of tribromophenol), then 5 Cc. of hydrochloric acid, and immediately insert the stopper. Shake the bottle repeatedly in the course of half an hour, then remove the stopper just sufficiently to introduce quickly 5 Cc. of a 20 per cent. aqueous solution of potassium iodide, being careful that no bromine vapor escapes, and immediately stopper the bottle. Shake the latter thoroughly, remove the stopper, and rinse it and the neck of the bottle with a little water, so that the washings may flow into the bottle, and then add 1 Cc. of chloroform and shake well. Add from a burette tenth-normal sodium thiosulphate solution until the iodine tint is exactly discharged and does not reappear after thorough agitation. Note the number of Cc. of tenth-normal sodium thiosulphate solution consumed. Deduct this from 30 (the number of Cc. of bromine solution originally added), and multiply the remainder by 4. The product will, approximately, represent the percentage of absolute phenol in the sample tested.

To estimate the quality of commercial phenol, Shoedler (1872) recommended its conversion into phenolsulphonic acid by heating it with an equal weight of sulphuric acid to 50° or 60° C. (122° or 140° F.), treating with barium carbonate, precipitating

the filtrate by sulphuric acid, and weighing the ignited barium sulphate, 100 parts of which correspond to 80.69 parts of anhydrous phenol.

The presence of phenol in watery solution may be detected, according to E. Hoffmann (1879), by pouring into a test-tube 1 or 2 Cc. of pure sulphuric acid, adding but not mixing an equal volume of aqueous liquid, and dropping in small particles of potassium nitrate, each of which will produce a deep-violet streak; on agitation the liquid becomes violet, and on the addition of water assumes a red-orange color; 0.1 per cent. of phenol may thus be detected. Salkowski's (1872) process consists in adding to the suspected liquid one-fourth its volume of ammonia, and then a few drops of solution of chlorinated lime (1 part in 20 parts of water). On the application of moderate heat, a blue or greenish color will be produced, either immediately or in the course of 15 minutes, the color changing to red upon acidulating with sulphuric or hydrochloric acid; 1 part of phenol in 4000 may thus be detected. Bromine may be used in place of the chlorinated solution; the blue compound is insoluble in ether and chloroform, dissolves in alcohol with a green color, and changes with acids to red, but becomes blue again by ammonia. Of still greater delicacy (1 in 200,000) is the test suggested by Plugge (1872): when a liquid containing phenol is boiled with a little solution of mercurous nitrate containing a trace of nitrous acid, reduction of the mercurous salt occurs, and the liquid assumes, sooner or later, an intense red color.

Under the name of *Crude carbolic acid, Acide phénique cru*, Fr., *Rohe Karbolsäure*, G., the Pharmacopœia of 1890 recognized a liquid consisting of various constituents of coal-tar, chiefly cresol and phenol, obtained by fractional distillation, and described it as colorless or of a reddish or brownish-red color and of a strongly empyreumatic taste and creosote-like odor. The commercial crude carbolic acid does not conform to this description, being usually of very dark color, almost black, and very disagreeable odor; in all probability it represents the residuary tarry liquor from which the phenol and cresol have almost wholly been abstracted. The former official crude acid corresponded to the commercial varieties known as Calvert's No. 4 and No. 5 carbolic acid. Crude carbolic acid as formerly sold, and still offered in the English market, is composed of varying proportions of crude phenol, cresol, rosolic acid, naphthalene, etc., besides water, and certain portions of it will crystallize at from 10° to 22° C. (50°–71.6° F.). It should not be soluble in less than 15 parts of cold water, and the aqueous solution should not show an alkaline reaction. If 50 volumes of the crude acid be agitated with 950 volumes of water and the mixture allowed to separate, not more than 5 volumes (10 per cent. of the acid used) should remain undissolved.

Aqua Carbolisata, P. G.; *Carbolized water, Phenol water*, E.; *Eau phéniquée*, Fr.; *Carbolwasser, Phenolwasser*, G.—Mix 22 parts of liquefied carbolic acid with 978 parts of distilled water. It contains 2 per cent. of pure carbolic acid by weight, or practically 146 grains in a pint. The preparation of the French Codex contains only 0.1 per cent. of phenol for internal use, and 1 per cent. if for external use.

Pharmaceutical Preparations.—Carbolized Gauze, Carbolized Oil, Iodized Phenol, N. F.; Carbolized Water, P. G.; Glycerite of Phenol, Ointment of Phenol, U. S.; Troches of Phenol, Br.

Lister's Catgut, for ligatures, is prepared by immersing for 2 days 200 parts of catgut in a freshly prepared mixture of 200 parts of phenol with 400 parts of water containing 1 part of chromic acid in solution; the gut is then dried without untwisting it, and preserved in a solution of 1 part of phenol in 5 parts of olive oil.

(See, also, Preparations of the National Formulary in Appendix.)

Action and Uses.—When locally applied to the skin, phenol produces burning pain, which is followed shortly by loss of tactile sensibility. The tissue at first is reddened, but later becomes blanched and anæsthetic. Burns from this drug are superficial, because it coagulates the albumin in the part it touches.

Phenol was at one time exclusively used as the antiseptic in surgical operations, but at present its use is limited chiefly to the cleansing of instruments and utensils. Because of its irritant action upon living tissues and its ready absorption from wounds, thereby causing symptoms of poisoning, and especially anuria, its use has been largely abandoned in surgical antisepsis.

Locally phenol is a caustic and anæsthetic. Its superficial action, however, renders it unfit for many of the conditions in which caustics are employed. 1 per cent. solutions

in water or olive oil are frequently employed in pruritus ani and vulvæ. 2 per cent. solutions often relieve the itching of jaundice and of many skin eruptions. It has many advocates in the treatment of parasitic skin diseases, and ointments containing from 5 to 10 per cent. of phenol form an excellent dressing in chronic, sluggish ulcers. 1 per cent. solutions may be employed in stomatitis and in the various acute inflammatory conditions of the throat as a mouth-wash or gargle. Care should be exercised in using phenol not to allow it to remain in contact with the skin of the fingers or toes, even in weak solutions, as it may cause gangrene or sloughing. In the form of Dobell's Solution it has been largely used in chronic nasal catarrh. A solution containing 8 grains (0.5 Gm.) of phenol to 1 fluidounce (30 Cc.) of water may be employed hypodermically in the abortive treatment of inguinal buboes. Injections of the pure phenol have been recommended in the treatment of hemorrhoids and hydrocele, but they often fail, and are always attended with a certain amount of danger. Phenol enters into the composition of Schleich's Fluid, a solution now largely employed in infiltration anæsthesia. 5 per cent. solutions may be used in the sick-room to disinfect the urine, stools, and soiled linen, but more potent preparations, such as solutions of formaldehyde, have largely supplanted it.

Internally, in the dose of from 1 to 2 grains (0.06–0.12 Gm.), it does good in obstinate vomiting, especially when it is due to gastric irritability; and combined with 15 to 20 grains (1.0–1.3 Gm.) of bismuth it is of service in fermentative diarrhœa.

Phenol depresses the peripheral sensory nerves when locally applied, and given internally in overdoses causes mental stupor which may be accompanied by clonic convulsions. Respiration and circulation are accelerated at first, but eventually the breathing becomes shallow and irregular, and the pulse running, rapid, and thready, death being due to respiratory failure. In fever it increases heat radiation and lessens its production in ordinary doses, but in poisonous amounts the great reduction in temperature which occurs is probably due in part to the collapse induced by the drug. It is eliminated by the kidneys as glycouronic acid, hydroquinone, and the sulphocarbolates of sodium and potassium. Large amounts irritate the kidneys, producing albuminuria and smoky colored urine. The urine sometimes causes reduction of Fehling's Solution.

Large lethal doses of phenol may produce immediate death, which is due to paralysis of the respiratory centre, or the individual may live for a number of hours, during which time he suffers from violent gastro-enteritis and burning pain throughout the gastro-intestinal tract. The mucous membrane of the mouth shows a wide eschar if the phenol be pure, a black or brown one if the phenol be impure, surrounded by a reddened zone of inflammation. In many cases vomiting and purging occur, but in some persons these symptoms are absent. Collapse usually appears early; the temperature falls; the skin is cold, clammy, and pallid; the face has an anxious expression; the respirations become rapid and shallow, and the pulse running, rapid, and thready, or even imperceptible. This condition is treated by the application of external heat, the administration of demulcents and opium to relieve pain, of stimulants to prevent or overcome shock, and of large quantities of any soluble sulphate, especially magnesium or sodium sulphate, which is the chemical antidote. The effects of phenol upon the skin may be neutralized completely by bathing the part in pure alcohol. Glycerin may also be employed, and is almost equally efficient.

Derivatives. — PHENOLSULPHONIC ACID.—*Sulphocarbolic acid, Sulphophenol, Sulphocarbol.* $C_6H_4(SO_3H)OH$. Molecular weight, 173.64.—Three different substitution-compounds of carbolic acid and sulphuric acid are known, distinguished by the prefixes ortho-, meta-, and para-. Orthophenolsulphonic acid is formed in the cold when equal parts of carbolic and sulphuric acids are left together for a week, whereas if the mixture be heated for 6 hours on a boiling water-bath, only the para- variety is produced; in either case the excess of sulphuric acid is removed by barium carbonate. The resulting sulphate is filtered out and the filtrate decomposed by addition of an exact amount of sulphuric acid, ascertained by a previous test, whereby the phenolsulphonic acid is liberated. It is a reddish- or amber-colored viscous liquid, of carbolic-acid-like odor and a caustic taste. It is readily soluble in water, alcohol, and glycerin. The ortho- acid in aqueous solution is gradually changed into the para- acid. The names *aseptol* and *sozolic acid* have been given to a 33⅓ per cent. solution of orthophenolsulphonic acid. It is a colorless or yellowish liquid of slight acid reaction and faint odor, which darkens upon exposure to light.

PHENOLPHTHALEIN. $C_{20}H_{14}O_4$.—Although not used in medicine, phenolphthalein is of considerable interest on account of its extensive use as an indicator in volumetric analysis. It is prepared by heating 10 parts of phenol with 5 parts of phthalic anhydride and 4 parts of

strong sulphuric acid to 120° C. (248° F.) for about 10 hours, exhausting the resulting product with boiling water, dissolving the residue in dilute sodium hydroxide solution, and precipitating with acetic acid. It may be purified by boiling its alcoholic solution with animal charcoal, and precipitating the filtrate with water, when it separates as a white or yellowish-white amorphous (or crystalline, if heated) powder. Phenolphthalein is almost insoluble in water, but readily soluble in alcohol, forming colorless solution. With alkalies it yields a red color, which is discharged by the slightest excess of acid, even carbon dioxide, but is not suited for determination of ammonia. The color is caused by formation of an alkali salt of phenolphthalein, which undergoes ionization in the presence of water. Phenolphthalein may be used in boiling as well as in cold liquids, and is employed in form of a solution in strong or diluted alcohol by dissolving 1 Gm. in 100 Cc. of the liquid. It is used as a delicate test for acids and alkalies.

TETRAIODOPHENOLPHTHALEIN.—*Nosophen; Iodophen.* $C_{20}H_{10}O_4I_4$.—A brownish-yellow, odorless, tasteless powder, obtained by adding a solution of 20 Gm. each of iodine and potassium iodide in 100 Cc. of water to a solution of 6 Gm. of phenolphthalein in 100 Cc. of water containing 8 Gm. of sodium hydroxide. The color of the latter solution changes from red to blue, and finally to yellow. Upon addition of hydrochloric acid the newly formed compound is precipitated, and may be further purified by resolution in sodium hydroxide solution and precipitation by acid. Nosophen is insoluble in water and acids, difficultly soluble in alcohol, but readily in ether, chloroform, and glacial acetic acid. It has been used both externally and internally as a non-toxic antiseptic agent. Compounds of tetraiodophenolphthalein with metals have been introduced under the following fanciful trade-names: Antinosin, sodium nosophenate or nosophen-sodium; Eudoxin, bismuth nosophenate or nosophen-bismuth; Apallagin, mercury nosophenate or nosophen-mercury; Asklepin, lithium nosophenate or nosophen-lithium. Eudoxin is used as an intestinal antiseptic in fermentative diarrhœa.

PHENACETOLIN or *Phenacetein*, $C_{16}H_{12}O_2$, is of interest in volumetric analysis as an indicator, since it permits the determination of caustic alkalies in the presence of alkali carbonates. It is obtained by boiling a mixture of 10 parts of phenol and 20 parts each of zinc chloride and acetic anhydride for 20 or 30 minutes, washing the resulting mass with water, and then digesting it with 5 per cent. nitric acid. After the solution has become clear, it is neutralized with ammonia, which causes the separation of phenacetolin in the form of red flocculi, which are insoluble in water, but soluble in alcohol. Solutions of phenacetolin are colored yellow by acids and caustic alkalies, but red by alkali carbonates.

CHLOROPHENOLS.—By action of chlorine on phenol, substitution compounds are obtained, some of which have been used medicinally, thus: Ortho-, Meta-, and Para-monochlorophenol, C_6H_4ClOH, the former a colorless liquid boiling at 175° C. (348.8° F.), the two latter, colorless crystals; Trichlorophenol, also known as Omal, $C_6H_2Cl_3OH$, colorless crystals, sparingly soluble in water, but soluble in alcohol, ether, and glycerin. It has been used as an antiseptic.

PHENOL LIQUEFACTUM, *U. S.*—Liquefied Phenol.

Acidum carbolicum liquefactum, Br., P. G.—*Liquefied carbolic acid*, E.; *Verflüssigte Karbolsäure*, G.

Preparation.—Phenol, a convenient quantity; distilled water, a sufficient quantity. Liquefy the phenol by placing the unstoppered container in a water-bath, and heat gradually until the crystals have melted; transfer the liquid to a tared vessel and weigh; then add for each 9 Gm. of phenol 1 Gm. of distilled water, and mix thoroughly. It should be kept in dark amber-colored, well-stoppered bottles.—U. S.

The directions of the Br. and P. G. are very similar, except that they direct 100 parts of phenol in crystals and 10 parts of water, thus making the finished product a trifle stronger in phenol.

Properties.—Liquefied phenol is a clear colorless liquid, which may develop a slight pinkish tint, and has a decided odor of phenol. It has a specific gravity of 1.070 at 15° C. (59° F.), 1.064 to 1.069 at 15.5° C. (60° F.), Br., 1.068 to 1.069, P. G., or 1.065 at 25° C. (77° F.), U. S., and boils at about 115° C. (239° F.) (boiling-point gradually rising to a temperature not higher than 188° C. (370.4° F.), U. S., or 182° C. (359.6° F.), Br.). Crystallization begins when the temperature of the liquid is lowered to about 13.5° C. (56.2° F.). It is soluble in 12 parts of water at 25° C. (77° F.), and is miscible with alcohol, ether, and glycerin in all proportions. 1 part of liquefied phenol acquires a permanent cloudiness when mixed respectively with 2 parts of chloroform, 1.5 parts of benzene, 2.5 parts of carbon disulphide, 2 parts of oil of turpentine, and 2.5 parts of olive oil. When thus deprived of water, it should respond to the tests given under PHENOL.—U. S. It forms a clear solution on the addition of 18 to 27 per cent. of water at 15.5° C. (60° F.).—Br. 10 Cc. of liquefied phenol should not become turbid upon addition of 2.3 Cc. of water at 15° C. (59° F.), but will do so upon further addition of 8 or 10 drops of water. If to the turbid mixture

not less than 135 Cc. nor more than 140 Cc. of water be added, a clear solution should result.—P. G.

Liquid phenol is composed of not less than 86.4 per cent. by weight of absolute phenol and about 13.6 per cent. of water, on which latter account it will not be possible to make perfectly clear solutions of the same with oil.

Action and Uses.—For the action and uses of Phenol Liquefactum, see PHENOL.

PHENYLIS SALICYLAS, *U. S.*—Phenyl Salicylate.

Salol, Br. (U. S. 1890); *Phenylum Salicylicum*, P. G.; *Salicylate de phénol*, Fr. Cod. —*Salol*, E.; *Salicylate de phényle*, Fr.; *Salol, Phenylsalicylat, Salicylsäurephenylester*, G.

Formula, $C_6H_4(OH)CO.OC_6H_5$ or $C_6H_5C_7H_5O_3$. Molecular weight, 212.47.

Phenyl salicylate was first introduced into medicine by Sahli in 1886, under the name of salol.

An ester obtained by the action of condensing agents upon a mixture of salicylic acid and phenol or the sodium compounds of the same.

Preparation.—When dehydrating agents are made to act upon a mixture of phenol and salicylic acid, phenyl salicylate is formed and water eliminated, For this purpose a mixture of sodium-phenol and sodium salicylate in molecular proportions may either be treated for some time with phosphorus oxychloride or a slow current of phosgene gas (carbonyl chloride) may be passed into a warmed mixture of the two salts: in the first case the secondary or by-products consist of sodium chloride and metaphosphate, and in the second case of sodium chloride and carbon dioxide. These are removed by washing the mass repeatedly with water, and recrystallizing the residuary salol from alcohol.

A later process, which has been patented, consists in heating pure or even crude salicylic acid in a flask with a long narrow neck in a bath to 220°–230° C. (428°–446° F.); air is excluded by keeping the flask filled with carbon dioxide, and the length of the neck permits only vapors of water and carbon dioxide to escape. The theory underlying the reaction is the conversion of some of the salicylic acid into phenol and carbon dioxide, the phenol reacting with the remainder of the salicylic acid forming phenyl salicylate with elimination of water, thus: $C_6H_4OHCOOH = CO_2 + C_6H_5OH$;—$C_6H_4OH + C_6H_4OHCOOH = C_6H_4OHCOOC_6H_5 + H_2O$.

Properties.—Phenyl salicylate occurs as a colorless, crystalline powder (colorless crystals, Br.), having a faint aromatic odor and very little taste. It is almost insoluble in water (1 in 2333), soluble in 5 parts of alcohol at 25° C. (77° F.), very soluble in hot alcohol, in ether, chloroform, and fixed and volatile oils (10 parts of 90 per cent. alcohol or ⅓ part of ether, at 15° C. (59° F.), Br., P. G.). When heated to 42° C. (107.6° F.) it melts, and at a higher temperature burns, leaving no weighable residue (melting-point 42°–43° C., Br.). If to an alcoholic solution be added diluted ferric chloride test-solution, a violet coloration is produced. If 0.2 to 0.3 Gm. of phenyl salicylate be dissolved in a little warm sodium hydroxide solution, and the solution be then acidified with hydrochloric acid, salicylic acid separates out and the odor of phenol is recognizable at the same time.—U. S. An alcoholic solution of salol gives a white precipitate with solution of bromine. On melting together salol and sodium hydroxide, and then acidulating with hydrochloric acid, a white precipitate is produced and phenol is evolved.—Br.

Tests.—Phenyl salicylate placed upon moistened blue litmus-paper should not produce any reddish coloration (absence of free acid). If 1 Gm. of phenyl salicylate, shaken with 50 Cc. of water, be filtered, the filtrate should show no color, or at most a trace, with ferric chloride test-solution previously diluted with 20 volumes of water (limit of uncombined salicylic acid and phenol). If a portion of the same filtrate be tested with barium-nitrate test-solution and silver-nitrate test-solution, it should show no turbidity (absence of sulphates and chlorides).—U. S.

Action and Uses.—Phenyl salicylate depends for its value upon its salicylic acid and phenol, into which it is decomposed in the alkaline secretions of the small intestine. Employed in the treatment of acute rheumatic fever, it can not be safely ingested in as large doses as the other salicylates, for the phenol liberated in the bowel may be sufficient in quantity to produce untoward effects. Even in somewhat smaller amounts it is apt to irritate the kidneys and darken the urine through the phenol oxidation products which are eliminated in this secretion, and must be given cautiously, if at all, when the kidneys are diseased. Because of its insolubility in the acid juices of the stomach it is adminis-

tered when this organ can not bear the other salicylates. In muscular and chronic articular rheumatism it is sometimes preferable to salicylic acid. Salol is one of the best intestinal antiseptics, and is of the greatest value in the treatment of duodenal catarrh, intestinal indigestion and fermentation, and all forms of choleraic diarrhœa. Its usefulness in typhoid fever is disputed. Being eliminated as educts of salicylic acid and phenol by the kidneys, it sterilizes and clears the turbid and ammoniacal urine of chronic cystitis, and in gonorrhœal urethritis tends to disinfect the urethra during each act of micturition. As a local antiseptic its slight solubility renders it of doubtful utility. Its dose is from 15 to 45 grains (1–3 Gm.) daily, in powders, pills, or capsules.

Allied and Derivative Compounds.—A number of compounds analogous to salol are in use among physicians, and at least two of them have been introduced into the French Pharmacopœia.

Cresyl Salicylate. Cresalol.—*Salicylate de Cresol*, Fr. Cod.—$C_6H_4(OH)CO_2C_6H_4CH_3$.—Cresalol is a crystalline compound obtained by the interaction of salicylic acid and cresol in the form of their respective sodium salts in the presence of phosphorus oxychloride. Three varieties are formed, depending on the particular sodium salt (ortho-, meta-, or para-) used. All are insoluble in water, but soluble in alcohol and ether. Paracresol salicylate is the kind generally employed; it occurs in colorless crystals which melt at 40° C. (104° F.).

Naphthyl Salicylate. Betol.—*Salicylate de Naphthol β*, Fr. Cod.—$C_6H_4(OH)CO_2C_{10}H_7$.—This compound, also known as naphthalol, naphthosalol, and salinaphthol, is prepared in a manner analogous to that followed for cresalol, simply substituting β-naphthol-sodium for cresol-sodium. It is a crystalline powder, without color, odor, and taste, and melts at 95° C. (203° F.). Insoluble in cold and hot water as well as glycerin, difficultly soluble in cold alcohol, but soluble in 3 parts of boiling alcohol, also in ether and benzene. Betol may be distinguished from salol by adding 2 or 3 Cc. of sulphuric acid to 0.1 Gm. of the salt, which yields a lemon-yellow solution in a very short time; upon addition of a trace of nitric acid to the solution, the color changes to olive green.

Salophen. *Acetylpara-amidophenol salicylate. Acetpara-amidosalol.* $C_6H_4.OH.CO_2.C_6H_4.NH.COCH_3$.—This compound was introduced in 1891 as a substitute for salol, from which it differs chiefly in yielding harmless acetylpara-amidophenol, instead of toxic phenol when decomposed in the human organism. It is prepared by a complicated process, the first step being the preparation of paranitrophenol salicylate in a manner similar to the production of salol; then converting this into para-amidophenol salicylate by means of reducing agents, and, finally, by the action of acetic acid, into acetylpara-amidophenol salicylate or salophen, which is purified by crystallization from benzene or alcohol. It occurs as minute white scales containing 50.9 per cent. of salicylic acid, is of neutral reaction, and is free from odor and taste. Salophen melts at 187° to 188° C. (368.6°–370.4° F.). It is insoluble in cold, but somewhat soluble in hot water, and is readily taken up by alcohol, ether, and solution of the alkalies. It is soluble in benzene, but not in petroleum ether. When salophen is heated with sulphuric acid and alcohol, the odor of acetic ether is developed. Ferric chloride added to an alcoholic solution of salophen produces a violet color, changing gradually to brownish yellow. Salophen dissolves colorless in concentrated sulphuric acid. The filtrate obtained after shaking salophen with water and filtering should give no color reaction with ferric chloride, or reaction for chlorides with solution of silver nitrate. If .10 Gm. of salophen be boiled for 1 minute with a solution of sodium hydroxide (1:2), cooled, and 5 Cc. of solution of chlorinated soda then added, a deep green will appear, changing to brown. On adding an excess of hydrochloric acid a bright scarlet color is developed, which changes to red orange (G. Beringer). Salophen boiled with a dilute aqueous solution of sodium hydroxide and allowed to cool, a blue color is gradually developed, beginning at the top. The color is discharged on again boiling the solution, and reappears on cooling. If now a few drops of dilute solution of carbolic acid and chlorinated lime be added to the solution a red color is developed, which turns to blue on adding excess of ammonia. Salophen should not be confounded with "saliphen," the name given to salicyl-phenetidin, a compound of salicylic acid and phenetidin introduced in 1890, and having the formula $C_6H_4OC_2H_5NHC_6H_4(OH)CO$.

Salicylamide. $C_6H_4(OH)CONH_2$.—This compound is produced by the action of dry ammonia gas on methyl salicylate in the form of oil of wintergreen. It is a colorless or slightly yellowish-white crystalline powder, melting at 138° C. (280.4° F.), and soluble in alcohol and ether; it requires about 250 parts of cold water for solution. Salicylamide is quite tasteless, but produces a gritty feeling between the teeth; treated with caustic soda, it is converted into sodium salicylate and ammonia.

Salol-camphor, *Camphol*, is a colorless or pale-yellow oily liquid, obtained by mixing 3 parts of salol with 2 parts of camphor, and heating gradually to complete fusion; it should be preserved in yellow hermetically sealed bottles, as it readily decomposes when exposed to light and air.

Diiodosalol. *Phenyl diiodosalicylate.* $C_6H_2I_2(OH)CO_2C_6H_5$.—A tasteless and odorless crystalline powder, obtained as a condensation-product of phenol with diiodosalicylic acid; it fuses at 133° C. (271.4° F.).

PHOSPHORUS, *U. S., Br., P. G.*—Phosphorus.

Phosphore, Fr.; *Phosphor*, G.; *Fosforo*, It., Sp.

Symbol, P. Atomicity, trivalent and quinquivalent. Atomic weight, 30.77.

Phosphorus should contain not less than 99.5 per cent. of the pure substance, and be carefully kept under water in a secure and moderately cool place, protected from light.—U. S.

Origin and Preparation.—Owing to its great activity, phosphorus occurs only in the combined state in nature, principally as tricalcium phosphate (*phosphorite, apatite*, etc.), also as aluminum phosphate (*wavellite*), and as iron phosphate (*vivianite*). The largest phosphate beds are in Florida. Phosphorus occurs in small quantities in all rocks, and, through weathering of these, in soils. It is an essential constituent of all fertile soils, especially so for the development of seeds. It plays a still more important rôle in the animal body, as it takes part in the formation of all parts of the organism, being found in bones to the extent of about 60 per cent. as calcium phosphate, and as an organic phosphorus compound (lecithine) in egg-white, muscle, nerve and brain substance, yolk of egg, etc. Phosphorus was discovered by Brandt (1669), of Hamburg, among the products of the dry distillation of urine, and about 1769 Gahn and Scheele detected the presence of phosphoric acid in bones, and the latter succeeded in isolating it in 1771. Up to about 6 years ago all phosphorus was prepared by treating calcined bones with sulphuric acid, decanting from the calcium sulphate, evaporating the solution of acid calcium phosphate, after mixing it with powdered charcoal and sand, to complete dryness, gently igniting and distilling the residue, composed of calcium metaphosphate, charcoal, and sand, in a stoneware retort. The different steps in the manufacture of phosphorus may also be explained by the following chemical equations: (1) $Ca_3(PO_4)_2 + 2H_2SO_4 = CaH_4(PO_4)_2 + 2CaSO_4$; (2) $CaH_4(PO_4)_2 = Ca(PO_3)_2 + 2H_2O$; (3) $2Ca(PO_3)_2 + 2SiO_2 + 10C_2 = P_4 + 2CaSiO_3 + 10CO$. In case the organic matter of bones is to be utilized in the manufacture of glue, the bones are treated with hydrochloric acid and the liquid treated as stated. The retort is connected with a wide bent tube which dips into water; a number of retorts are placed in each furnace, and after the distillation is completed the melted phosphorus is strained under water and run into tubes of suitable size, where it congeals. This process is now practically superseded by the one introduced by Readman, which consists in preparing phosphorus directly from calcium phosphate or aluminum phosphate mixed with carbon and sand or clay by heating in an electric furnace. The method is not one of electrolysis, but simply the utilization of the high temperature which is produced by an electric current. A very pure and large yield of phosphorus is obtained. The works at Niagara Falls supply the domestic needs. The chief application of phosphorus is for making matches, smaller quantities being used in the manufacture of phosphor-bronze, rat poisons, compounds of phosphorus, and for medicinal purposes.

Properties.—Phosphorus occurs in commerce in the form of cylindrical sticks, which are nearly colorless or pale-yellow, transparent or translucent, of a waxy lustre, and about as hard as beeswax, and flexible at ordinary but brittle at low temperatures. It is inodorous and tasteless, but in contact with air it has an alliaceous odor and taste, and emits white vapors, which are luminous in the dark (phosphorescence). It is very easily inflammable in the air, burning with a brilliant white flame and giving off dense white vapors of phosphoric anhydride, and must be preserved and cut under water, in which it is insoluble. Its specific gravity is 1.830 at 10° C. (50° F.), and 1.820 at 25° C. (77° F.), U. S.; 1.77 at 15.6° C. (60° F.), Br.; and when fused at 44° C. (111.2° F.) is 1.743. It melts at 44° C. (111.2° F.), U. S., P. G.; at 43.3° C. (110° F.), Br.; and may be cooled to 40° C. (104° F.) before it congeals again—under certain circumstances even to 4° C. (39.2° F.), as observed by Bellani (1813). The boiling-point of phosphorus is 288° C. (550° F.), according to Dalton; 290°C.(554° F.), Hager; Mitscherlich found it at 260°C. (500° F.); but it volatilizes slowly with the vapors of boiling water; the density of its vapor is 4.3. According to Joubert, phosphorus is not luminous in pure oxygen below 14° C. (57° F.) unless the pressure is diminished or the oxygen is mixed with an indifferent gas; the luminosity is prevented in the presence of hydrogen sulphide, of vapors of alcohol, ether, and other compounds. Phosphorus is soluble in alcohol, ether, fixed and volatile oils; it dissolves in 350 parts of absolute alcohol at 15° C. (59° F.), in 240 parts of boiling absolute alcohol, in 80 parts of absolute ether, in about 50 parts of any fatty oil, in about 25 parts of chloroform, and in about half its weight of carbon disulphide, the latter

yielding a solution which must be handled with the greatest care to prevent evaporation, which is followed by instant ignition.—U. S. It is more freely soluble in sulphur chloride and in benzene. Phosphorus crystallizes after fusion when slowly cooled, and from its solutions in volatile oils and carbon disulphide. It unites directly with oxygen, sulphur, chlorine, iodine, bromine, and with many metals, and precipitates some of the latter from their solutions. When kept in water and exposed to light and air it is superficially corroded, and becomes white and opaque (Baudrimont, 1865), while phosphorous acid is found in the water; the change does not take place in water which is free from air, nor does phosphorus lose its transparency when kept in the dark. Commercial phosphorus frequently contains a little arsenic, from which it can not be freed by distillation.

Tests.—The impurities likely to be present in phosphorus are derived from the sulphuric acid used in its preparation, and are mainly arsenic and sulphur; a small proportion of the latter renders phosphorus hard and rather brittle at ordinary temperatures. In the following test the U. S. P. has adopted a limit of 0.05 per cent. of arsenic, or 1 part in 2000 of phosphorus: Add 1 Gm. of phosphorus to a mixture of 10 Cc. each of nitric acid and distilled water, contained in a flask having the capacity of 50 Cc., and digest at a gentle heat on a water-bath while passing a current of carbonic acid gas into the flask over the surface of the fluid, until the phosphorus is dissolved. Transfer the solution to a capsule, and evaporate it until no more nitrous vapors are given off, and then dilute the solution to 100 Cc. with distilled water. 1 Cc. of this solution should not respond to the modified Gutzeit's test for arsenic (see Arseni Trioxidum). The official limit of sulphur is determined by adding barium chloride test-solution to the remainder of the liquid, when not more than a slight opalescence should be produced.

Amorphous or Red Phosphorus.—This was discovered by Schrötter (1848) by heating ordinary or vitreous phosphorus for a long time to 250°–260° C. (482°–500° F.) in an atmosphere in which it can not burn. It is an amorphous dark-red mass or powder, becomes nearly black on being boiled with potassium hydroxide solution, is insoluble in simple solvents, remains unaltered in dry air, and enters into chemical combinations less readily than the ordinary variety. According to Hittorf (1865), it has the specific gravity 2.19, is infusible, volatilizes slowly above 260° C. (500° F.), and, according to Lemoine (1867), is best converted into ordinary or vitreous phosphorus by heating to near 450° C. (842° F.) in an atmosphere of nitrogen. At the temperature stated, Hittorf observed it to be converted into another modification, which forms black laminæ of a metallic lustre, is less volatile than amorphous phosphorus, but, like the latter, is gradually converted by heat into ordinary vitreous phosphorus.

Black Phosphorus.—As long ago as 1800 it was reported that phosphorus when treated with ammonia gas would deposit a brownish-black powder; the same phenomenon was observed later on by Thenard, Vogel, Wild, and in 1865 by Blondlot. Flückiger, who carefully examined the subject in 1892, came to the conclusion that the so-called black modification of phosphorus is nothing but arsenic in metallic form; by treating ordinary phosphorus repeatedly with ammonia-water of 0.920 specific gravity until all phosphorus has been removed, mainly in the form of phosphine, a black residue in powder-form eventually remains, which is permanent in the air and was proved to be arsenic (*Arch. d. Phar.*, 1892).

Detection of Phosphorus in Poisoning.—A preliminary step is to examine carefully the vomit, contents of the stomach, or residual food, in order to observe any odor of phosphorus, or any luminosity on stirring the matter in the dark, or the presence of pieces of phosphorus or residues of matches. If this examination proves negative, the distillation-test of Mitscherlich is tried, which must be conducted in a dark room. The material to be tested is acidified with tartaric or sulphuric acid, introduced into a flask with sufficient water to make a soft, pasty mass, the flask is closed with a 3-hole stopper and connected by an inverted U-tube with an upright Liebig condenser, the lower end of which dips under water contained in a flask. By tubes passing through the stopper the distilling flask is connected with a carbon dioxide generator and a steam supply. After filling the apparatus with carbon dioxide the flask is heated to boiling and steam passed through it. If phosphorus is present, it is volatilized and produces a faint yellowish-green glow at the point where the steam begins to condense. If phosphorus is present in sufficient quantity, small granules may collect in the receiver. To obtain the glow, the carbon dioxide should be shut off when distillation begins. For additional proof of phosphorus, a portion of the distillate is treated with 200 Cc. of strong chlorine-water,

set aside in a corked flask for some time, evaporated to 10 Cc. on a water-bath, and tested for phosphoric acid by ammonium molybdate solution. After 12 hours the yellow precipitate may be filtered, washed, dissolved in ammonia-water, precipitated by magnesia mixture, and the crystals of ammonium magnesium phosphate examined under the microscope for the characteristic "coffin-lid" shape.

In the above distillation-test the luminosity may be diminished or entirely prevented by the presence of alcohol, ether, chloroform, benzin, petroleum, turpentine, hydrogen peroxide, corrosive sublimate, carbolic acid, and when the mass in the flask is alkaline. Hypophosphorous, phosphorous, and phosphoric acids are not volatilized by steam, but yellow phosphorus is.

The method of Dusart-Blondlot may be employed if no luminosity appeared in Mitscherlich's method because of disturbing factors mentioned above or of the oxidation of phosphorus to phosphorous acid before it is tested. Some of the original material rubbed up with water and filtered, is introduced into a hydrogen-generating apparatus with pure zinc and sulphuric acid, the exit-tube of which dips under a 5 per cent. solution of silver nitrate. Phosphorus and the acids of phosphorus lower than phosphoric, are converted to phosphine gas, PH_3, which acts on silver nitrate, forming a black precipitate of silver phosphide, PAg_3. The generation of hydrogen should last for 12–24 hours, in a dark place. The PAg_3 is gathered in a porcelain dish, washed several times, and introduced into another hydrogen apparatus, to which is attached a U-tube filled with pumice-stone moistened with caustic alkali, to absorb any hydrogen sulphide, and a right-angle tube tipped with platinum. If phosphorus is present in the silver precipitate, PH_3 is formed, which gives a green color to the hydrogen flame at the platinum tip. Of course, a blank experiment should be made to test the color of the flame before introducing the silver phosphide precipitate, and the possibility of the patient having taken hypophosphites as medicine should not be overlooked. All substances which give a green-colored flame, such as hydrochloric acid, chloroform, and similar organic chlorine products, must not be present in the test. For fuller details of the above tests, the reader is referred to text-books on chemistry or toxicology.

Pharmaceutical Preparations.—Phosphorated Oil, Br.; Pills of Phosphorus, U. S.

Action and Uses.—Phosphorus is an exceedingly lethal poison. While it is true that when large masses are swallowed it will escape through the intestines without being dissolved, when in a finely divided state it is absorbed with sufficient rapidity to produce death by reason of the inflammatory changes which it causes, and because of the widespread fatty degeneration which takes place in all the organs of the body. Phosphorus is most frequently taken as a poison from matches, and has often been called the "servant girls' poison," because it has been used so frequently with suicidal intent by this class of persons.

There are two peculiar features of phosphorus-poisoning. The symptoms frequently do not manifest themselves for 8 or 12 hours after the drug has been swallowed, unless perchance vomiting comes on, when the vomit may be phosphorescent when examined in a dark room. The early symptoms consist in abdominal pain which is severe, vomiting, collapse, and a tenderness of the belly-walls; the urine becomes scanty and it may be albuminous, and fat-globules may appear in it. Another peculiarity of the poison is that after 24 to 36 hours the symptoms of poisoning undergo a marked remission, so that every one feels encouraged for the patient's recovery. A few hours after this, however, the symptoms return with greater violence than before, coffee-ground vomit is expelled, and death almost inevitably occurs. Diarrhœa is rarely met with. Constipation, however, is frequent, and the stools after the first few days are clay colored, owing to the action of the phosphorus upon the liver, which organ is frequently swollen and tender. The urine becomes scanty, owing to the action of the drug on the kidneys. Convulsive seizures are rarely met with. The antidote to phosphorus is potassium permanganate or hydrogen peroxide, which act by virtue of their oxidizing properties. French ozonized oil of turpentine and sulphate of copper, which have been recommended as antidotes, are useless. The former because it is not a true antidote so far as the chemical influence is concerned, and the second because it is a more rapidly acting poison than the phosphorus itself if given in quantities which are sufficiently large to influence the phosphorus.

Phosphorus is employed in medicine in the dose of $\frac{1}{100}$ grain (0.0006 Gm.), 3 times

a day, in cases of nervous exhaustion, sexual impotence, in rickets, and in other disorders of the nervous and bony systems characterized by poor development. Its exact value as a medicine is under discussion, some practitioners regarding it highly and others thinking it of little value. Owing to its very disagreeable taste, it had better be given in pill-form, although it may be administered in the form of the oil (Oleum Phosphoratum).

PHYSOSTIGMA, *U. S.*—Physostigma.

Physostigmatis semina, Br.; *Semen Calabariensis*, Belg.; *Faba Calabarica.—Calabar bean, Ordeal bean, Chopnut*, E.; *Kalabarbohne*, G.; *Fève de Calabar*, Fr.; *Haba del Calabar, Esere*, Sp.; *Favo de Calabar*, Port.

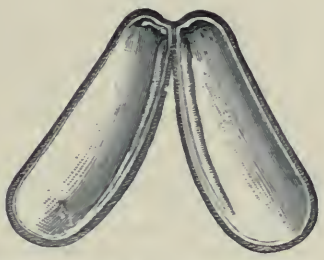
The dried ripe seed of *Physostigma venenosum* Balfour (Fam. *Leguminosæ*), yielding, when assayed by the U. S. P. process, not less than 0.15 per cent. of ether-soluble alkaloids.

Calabar bean is official in nearly all pharmacopœias. The Portuguese mentions that the episperm should be removed upon being used.

FIG. 304.

Calabar bean: view from the side and edge, showing length of hilum.

FIG. 305.



Calabar bean, split, showing cotyledons.

FIG. 306.

Physostigma cylindrosperma seed.

Origin.—From a high-climbing, woody twiner, native of western tropical Africa, somewhat naturalized in India and Brazil. It resembles the Scarlet runner and Lima bean, bearing pendulous racemes of handsome dark-purple, bean-like flowers and short, broad, 2- to 3-seeded pods.

Description.—2 to 3 Cm. (about 1 In.) long, 1.5 to 2 Cm. (about ¾ In.) broad, and 1 to 1.5 Cm. (about ½ In.) thick, oblong and subreniform, a broad furrow extending along the entire length of the convex edge, its reddish, rounded margins elevated and somewhat thickened; externally of a deep-chocolate color, shining, finely granular-tuberculate; embryo with a short, curved caulicle, and 2 large, white, concavo-convex cotyledons, enclosing an oblong cavity; inodorous; taste bean-like.

On moistening the embryo with potassium hydroxide test-solution, it becomes pale yellow.

The seed of *P. cylindrosperma*, often substituted, is here shown (Fig. 301). The seeds of a *Mucuna*, and those of *Entada scandens* Benth., both of the same family, have been reported as offered in place of Calabar beans. Both are lenticular, the latter very large, and neither could deceive the purchaser.

Constituents.—The important constituent of Calabar bean is *physostigmine (eserine)*, considered below. With it are associated 3 other alkaloids, as follows: *Calabarine*, not yet obtained in a pure condition, is a liquid, soluble in alcohol and water, but not in ether. Its presence is important, since it acts in some respects antagonistically to physostigmine. *Eseridine* ($C_{15}H_{23}N_3O_3$) occurs in white 4-sided crystals, soluble in alcohol, ether, and chloroform, and melting at 132° C. (269.6° F.). It acts similarly to physostigmine. *Eseramine* ($C_{16}H_{25}N_4O_3$) is crystalline and devoid of physiological activity. *Phytosterin* is a neutral body resembling cholesterin, crystallizing from ether, chloroform, and petroleum benzin in silky needles and from hot alcohol in scales. It is apparently inactive. Calabar bean also contains about half its weight of starch and 23 per cent. of proteids, with a little gum and fat. The ash amounts to between 3 and 4 per cent. The alkaloids exist mainly in the cotyledons, but the testa also possesses medicinal activity.

The alkaloid physostigmine, recognized in the French Pharmacopœia as ésérine, $C_{15}H_{21}N_3O_2$, was first found in the seed of the Calabar-bean plant by Jobst and Hesse in 1864. It is present to the extent of 0.1 per cent. and may be extracted by exhausting the powdered seed with warm alcohol containing about 1 Gm. of tartaric acid per litre. After recovery of the alcohol, the residue is taken up with water and filtered to remove resinous matter; the solution is then treated twice with ether, as long as this becomes colored, after which it is rendered alkaline by addition of sodium bicarbonate, and finally repeatedly shaken out with ether. Upon spontaneous evaporation of the ethereal liquid, the alkaloid will be obtained in the form of scaly crystals which may be further purified by recrystallization from ether.

Physostigmine occurs in thin rhomboidal lamella, which are colorless, but gradually assume a rose tint and even a yellow color, especially when exposed to air. By spontaneous evaporation of a solution in benzene, large crystals melting at 105° to 106° C. (221°–222.8° F.) may be secured. If crystallized from ether saturated with water, physostigmine takes up a molecule of water, which is, however, lost upon heating to 100° C. (212° F.). It is difficultly soluble in water, but readily so in alcohol, ether, chloroform, benzene, and carbon disulphide. Physostigmine is lævogyrate, and possesses a strong alkaline reaction. It is colored red by dilute solutions of caustic alkalies. When dissolved in concentrated sulphuric or nitric acid a yellow solution is produced, which in the latter case soon changes to olive green.

The alkaloid is readily decomposed. Its aqueous solution soon assumes a red color, more readily when heated, and leaves upon evaporation a cherry-red, amorphous residue, which is insoluble in ether, but soluble in chloroform, and which has been given the name *rubreserine*. Solutions of salts of physostigmine behave in like manner.

Assay of Calabar Bean.—Calabar bean in fine (No. 60) powder, 20 Gm.; ether, solution of sodium bicarbonate, 5 per cent.; normal sulphuric acid, distilled water, tenth-normal sulphuric acid, fiftieth-normal potassium hydroxide solution, hematoxylin or iodeosin test-solution, each a sufficient quantity. To 20 Gm. of powdered physostigma add 200 Cc. of ether and shake well for 10 minutes. Then add 10 Cc. of a 5 per cent. sodium bicarbonate solution, and shake vigorously at intervals for 4 hours. Let settle, and decant 100 Cc. of the ethereal solution into a separator, to which add sufficient normal sulphuric acid to make it acid, and add 10 Cc. of distilled water. Shake well for several minutes, and draw off the aqueous layer into another separator. Repeat the extraction, using 2 Cc. of normal sulphuric acid and 8 Cc. of distilled water, and adding the acid aqueous layer to the second separator. Finally, repeat again, using 1 Cc. of normal sulphuric acid and 9 Cc. of distilled water, and draw this also off into the second separator. To the combined acid liquids in the second separator add 25 Cc. of ether and sufficient 5 per cent. sodium bicarbonate solution to make them alkaline. Shake for a few minutes, let separate, and draw off the ether into a beaker. Repeat with 20 Cc. and again with 15 Cc. more of ether, added to the separator, shake for 2 minutes, let separate, and draw off into the beaker. Evaporate the ether from the combined ethereal solutions in the beaker carefully on a water-bath, and when dry, dissolve in 5 Cc. of one-tenth normal sulphuric acid and 20 Cc. of ether, which must be strictly neutral, and transfer this solution to a bottle, rinsing with 80 Cc. of water; add 5 drops of iodeosin test-solution and titrate the excess of acid with fiftieth-normal potassium hydroxide solution until, after shaking, the aqueous liquid just acquires a pink color. Divide the number of cubic centimetres of fiftieth-normal potassium hydroxide solution used by 5, subtract this number from 5 (the 5 Cc. of one-tenth normal acid used), multiply the remainder by 0.0273, and this product by 10 (or multiply at once by 0.273), which will give the percentage of ether-soluble alkaloids in the drug.—U. S.

Pharmaceutical Preparations.—Extract of Physostigma, Tincture of Physostigma, U. S. P.

Action and Uses.—Physostigma when taken in poisonous dose by man produces vomiting, pain in the belly, dyspnœa, vertigo, and great weakness, with contraction of the pupil and an increase in salivary and dermal secretion. Often marked muscular twitching develops, and this is followed by collapse. The pulse is usually quite slow. Consciousness usually remains intact until the near approach of death.

The dominant action of the drug upon the nervous system is to depress the motor portions of the spinal cord, and death is due to paralysis of the respiratory centres. The slow pulse is due to a direct action of the drug on the heart muscle.

Upon the unstriped muscular fibres of the stomach and bowels the drug acts as a powerful stimulant, and it increases practically all the secretions. In the eye the contraction of the pupil is due to stimulation of the oculomotor nerves peripherally, and intra-ocular tension is decreased.

The treatment of poisoning by physostigma consists in the free use of its physiological antidote atropine, and the use of internal heat and respiratory and cardiac stimulants, such as ammonia, ether, and digitalis.

When the alkaloid calabarine is present in excess in the drug, and it is taken in overdose, convulsions develop.

Physostigma is used for several therapeutic purposes. It is often added to laxative pills to increase their efficacy, and may be used to aid in the expulsion of flatus. It may also be employed in cases of chronic bronchitis to aid expectoration. The most common use of the drug is in the form of its alkaloid physostigmine, or eserine, as a myotic to contract the pupil and to decrease intra-ocular pressure in glaucoma. For this purpose the strength of the solution is about 1 to 2 grains (0.06–0.12 Gm.) to the ounce (30 Cc.) of water.

The dose of the extract is $\frac{1}{8}$ of a grain (0.008 Gm.); of the tincture, 5 to 20 minims (0.3–1.30 Cc.). The alkaloid physostigmine is given in the dose of $\frac{1}{80}$ of a grain (0.0008 Gm.).

Tanghinia seeds (see *Cerbera*, under APOCYNACEÆ) are also used as an ordeal poison, in Madagascar, much as Calabar beans are employed.

PHYSOSTIGMINÆ SALICYLAS, *U. S.*—Physostigmine Salicylate.

Physostigminum Salicylicum, P. G.—*Eserine salicylate*, E.; *Salicylate d'ésérine*, Fr.; *Physostigminsalicylat, Eserinsalicylat*, G.

Formula, $C_{15}H_{21}N_3O_2C_7H_6O_3$ or $C_6H_4(OH)COOH.C_{15}H_{21}N_3O_2$. Molecular weight, 410.21.

The salicylate of an alkaloid obtained from physostigma.—U. S.

Preparation.—No official process of manufacture is given. Hager recommends to neutralize a solution of 2 parts of physostigmine in warm ether with a solution of 1 part of salicylic acid in ether, and to allow the newly formed salt to crystallize.

Properties.—Physostigmine salicylate occurs in colorless or faintly yellowish, shining, acicular or short columnar crystals, without odor, and having a slightly bitter taste. When long exposed to light and air, it acquires a reddish tint, which change is hastened by the presence of ammoniacal vapors. The salt is usually slightly acid and dissolves at 15° C. (59° F.) slowly in 85 parts of water, and rapidly in 12 parts of alcohol. "It is soluble at 25° C. (77° F.) in 72.5 parts of water, and in 12.7 parts of alcohol; at 80° C. (176° F.) in 15 parts of water, and at 60° C. (140° F.) in 4 parts of alcohol; also soluble at 25° C. (77° F.) in 175 parts of ether and in 8.6 parts of chloroform. Its aqueous solution is acid to litmus-paper, and turns pink on standing 24 hours. When heated, the salt begins to soften, and turns slightly yellow at 160° C. (320° F.), and melts at 178.9° C. (354° F.). It leaves no residue on incineration. The addition of ferric chloride test-solution to an aqueous solution of the salt produces a deep-violet color, while calcium hypochlorite solution causes a red color. Aqueous solutions of the salt turn cherry red upon addition of a drop of caustic alkali solution, changing to a darker red, and finally to a green color. On evaporating aqueous solutions of the salt to dryness with a few drops of ammonia-water, a blue residue is produced, which is soluble in alcohol, and when so dissolved, yields a red fluorescent solution on the addition of an excess of acetic acid. If a few milligrammes of the salt be dissolved in nitric acid, a yellow solution results, which on being heated changes to orange and then blood red, and on evaporation to dryness, yields a green residue. When exposed to the fumes of nitric acid, this residue becomes violet blue, and when a drop of nitric acid is added to it, it forms a beautiful reddish-violet solution, which soon changes to blood red, and, finally, on standing, or on dilution, becomes greenish yellow. Sulphuric acid containing in each Cc. 1 drop of formaldehyde solution gives a bright-pink color when added to the salt; if sulphuric acid and a few grains of cane-sugar be added, a yellow color is produced, turning to brown, then to purple, and finally to greenish black."—U. S.

Tests.—Physostigmine salicylate should have all the properties described above. Platinic chloride test-solution produces no precipitate in solutions of the salt (distinction from *physostigmine sulphate*).

The salicylate of physostigmine is preferred to other salts of the alkaloid on account

of its greater stability. It should be kept in small, dark amber-colored, well-stoppered vials.

Action and Uses.—Physostigmine salicylate is used to contract the pupil of the eye, and to decrease intra-ocular tension in glaucoma. The solution freshly made should contain from 1 to 2 grains (0.06–0.12 Gm.) to the fluidounce (30 Cc.) of water. It is given hypodermically in the dose of $\frac{1}{64}$ to $\frac{1}{12}$ of a grain (0.001–0.005 Gm.) as a prophylactic and a cure for distention of the bowel, particularly after ether anæsthesia.

PHYSOSTIGMINÆ SULPHAS, *U. S., Br.*—Physostigmine Sulphate.

Physostigminum sulfuricum, P. G.; *Sulfate d'ésérine*, Fr. Cod.; *Eserine sulphate*, E.; *Physostigminsulfat, Eserinsulfat*, G.

Formula, $(C_{15}H_{21}N_3O_2)_2H_2SO_4$. Molecular weight, 643.75.

The sulphate of an alkaloid obtained from physostigma.—U. S.

Preparation.—The French Pharmacopœia alone directs the preparation of the salt, as follows: To a solution of physostigmine in ether is added, drop by drop, 10 per cent. sulphuric acid until separation of the newly formed salt no longer occurs. After filtration the physostigmine sulphate is carefully dried at a temperature of about 40° C. (104° F.).

Properties.—Physostigmine sulphate occurs as a white or yellowish-white, microcrystalline powder, odorless, and having a bitter taste. It is very deliquescent when exposed to the air, and gradually turns reddish by exposure to air and light. The salt is very soluble at 25° C. (77° F.) in water and in chloroform, in alcohol at 60° C. (140° F.). It is also soluble in 1200 parts of ether. When heated to 130° C. (266° F.) the salt becomes soft, and melts at about 140° C. (284° F.). Upon ignition, it is slowly consumed, leaving no residue. Its aqueous solution is acid to litmus-paper. Barium chloride test-solution produces a white precipitate, insoluble in hydrochloric acid. Aqueous solutions of the salt yield, with alkalies, a white precipitate, which immediately turns pink, and dissolves in excess of the alkali, forming a pink or red solution, which soon fades to a yellowish green. Gold chloride test-solution gives with aqueous solutions of the salt a beautiful purple color. Sulphuric acid added to the salt produces only a faint yellow color; but if the acid contain a crystal of potassium iodate, on being added to a crystal of the salt it gives a light-purple color, immediately changing to yellowish red, with a bordering ring of lavender.—U. S. "An aqueous solution of physostigmine sulphate, when shaken with a dilute solution of potassium hydroxide, becomes red; and when mixed with a solution of ammonia and evaporated to dryness on a water-bath it leaves a bluish residue, the solution of which in dilute acids is dichroic, being red by reflected and blue by transmitted light. A dilute aqueous solution applied to the eye causes contraction of the pupil."—Br. The salt dissolves in fuming nitric acid with a yellow color, which upon evaporation and drying turns to green.

Tests.—Platinic chloride test-solution added to aqueous solutions of physostigmine sulphate causes a yellowish-white precipitate (distinction from *physostigmine salicylate*).

Like the preceding salt, physostigmine sulphate must be preserved in small well-stoppered, dark amber-colored vials. Owing to its very hygroscopic character, weighing of the salt must be done with care and is best carried out on a tarred watch-glass.

Action and Uses.—(See PHYSOSTIGMINÆ SALICYLAS.)

PHYTOLACCA, *U. S.*—Phytolacca.

Virginia poke, Garget, Scoke, American or *Red nightshade, Coakum*, E.; *Scharlachbeere, Kermesbeere*, G.; *Agouman, Morelle a grappes*, Fr.; *Mazorquilla, Namoli, Jabonera*, Sp.

1. PHYTOLACCÆ RADIX, U. S., *Poke-root, Garget-root, Jalap Cancer-root, Mechoacan.* The dried root of *Phytolacca decandra* L. (Fam. *Phytolaccaceæ*).

2. PHYTOLACCÆ FRUCTUS (*P. Bacca*, U. S. 1880).—*Pokeberry, Garget-berry, Pigeon-berry, Red-ink berry*, E.; *Amerikanische Kermesbeere*, G.; *Raisin d'Amérique*, Fr. The fruit of *Phytolacca decandra* L. (Fam. *Phytolaccaceæ*).

Phytolacca is not official in any other pharmacopœia.

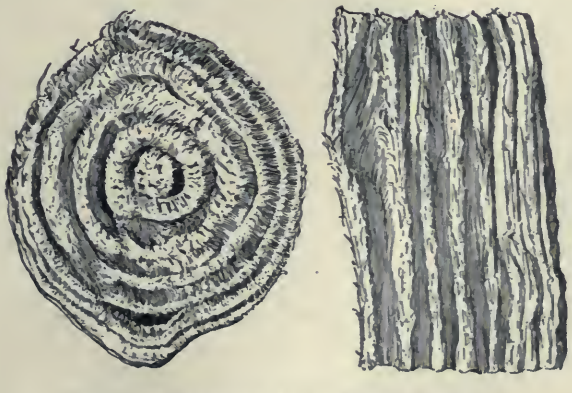
Origin.—The Poke-root plant is a very common, smooth perennial roadside weed in eastern and central North America, of which region it is the largest herb. In the Southern States it frequently reaches a height of 10 or 12 feet and a breadth almost as great. The stem is often several inches in diameter, purplish green and hollow, with thin, transverse partitions at intervals. The habit of foliage, inflorescence (greenish white), and fruit (deep crimson) are shown in the accompanying illustration. The root is very long, thick, and fleshy, considerably resembling horse-radish root, a resemblance which has been the occasion of numerous poisoning accidents, and which is aided by the acrid taste in deceiving those unfamiliar with it. The young shoots of spring are often eaten like Asparagus, but care is taken not to cut too deeply, and that they be thoroughly cooked. The rich purple juice of the berries is largely used in Europe for coloring wine, its color brightened by acids and turned bottle green by alkalies. Although the berries are reported somewhat poisonous, and this view is supported by evidence, this is apparently not true of their juice, since Eymard found that 80 Gm. (about 2½ ounces) were required to act as a cathartic. For medicinal purposes, the root should be collected in the fall.

FIG. 307.

Phytolacca: flowering branch and fruit (⅔ Nat.).

Description.—*Phytolacca fruit* forms a close and heavy, agglutinated, purple-black mass, the stones conspicuous as brightly shining particles. There is little odor, but a fruity, acidulous and sweetish, somewhat acrid taste. An individual fruit, in the fresh condition, or after being soaked, is a depressed-globular compound drupe, about 8 Mm. (⅓ In.) broad, consisting of 10 carpels, each possessing a fleshy outer portion (sarcocarp), enclosing a thin putamen containing

FIG. 308.



Phytolacca: transverse and longitudinal sections.

a seed in which the embryo is curved around a mealy albumen. The fleshy portions of the carpels are confluent around a short axis.

The *root* occurs mostly in transverse or longitudinal slices of sparingly branched, cylindrical, somewhat tapering, usually twisted roots, rarely exceeding 7 Cm. (3 In.) in diameter, externally of a rich or yellowish brown, finely longitudinally or spirally wrinkled and thickly annulate with lighter colored, low ridges; transverse slices exhibiting several concentric rings of interrupted wood-wedges, the intervening zones much retracted; longitudinal slices exhibiting the wood-bundles as bands, with the intervening medullary tissue greatly retracted; fracture fibrous; internally yellowish gray; inodorous, the powder highly sternutatory; taste sweetish, afterward highly acrid.

The powder is light gray. It contains numerous rounded or oval starch-grains measuring 10 to 20 mikrons, the hilum somewhat eccentric and slightly fissured, the rings indistinct except in the larger grains. Numerous acicular raphides are found, the bundles 50 to 75 mikrons long, 25 to 40 mikrons broad (*Nelson*).

Constituents.—The chemical composition of Poke-root is very peculiar. Its important active and poisonous constituent is an amorphous, bitter, and acrid substance very similar to, if not identical with, saponin. This is probably the glucoside reported by Coscera. The alkaloid *phytolaccine* exists in very small amount. It occurs in white crystals, soluble in alcohol and somewhat in water, nearly insoluble in ether and chloroform. *Phytolaccic acid* is amorphous, soluble in water and alcohol, reduces silver salts, and yields with earths and alkalies soluble salts, from which boiling hydrochloric acid separates the acid as a jelly. Sugars exist to the extent of nearly 10 per cent., and of starch there is an equal or greater amount. A little free formic acid, besides nearly 2 per cent. of potassium formate was obtained by Frankforter, as well as 6.2 per cent. of calcium oxalate. The same chemist found more than 13 per cent. of ash, nearly half of which was potassium oxide. The important constituent of the fruit, aside from the coloring-matter, is phytolaccic acid. Various fruit-acids occur. The coloring-matter is soluble in water, but not in alcohol, ether, or chloroform. Phytolaccin is a tannin-like substance. The ash amounts to 8 or 10 per cent. The poisonous constituents of the fruit are apparently confined almost, if not wholly, to the seed.

Pharmaceutical Preparation.—Fluidextract of Poke Root.

Action and Uses.—Phytolacca is rarely used in medicine. At one time it enjoyed quite a reputation in the treatment of chronic rheumatism, particularly that of syphilitic origin. Internally in the form of the tincture or decoction and externally in an ointment (1 drachm to the ounce—4–30 Gm.) it has been employed with some success in tinea, favus, scabies, and other skin diseases. Although used as an emetic, it is not a safe drug for this purpose. Toxic doses produce vomiting, purgation, great prostration, and in some instances death.

The dose of the powdered root, as an emetic, is 10 to 30 grains (0.60–2 Gm.). A saturated tincture is given in the dose of 1 drachm (4 Cc.) 3 or 4 times a day.

Allied Species.—The genus *Phytolacca* L. contains about a dozen species, mostly of tropical America. They are mostly similar in all respects to the official, and apparently contain the same constituents and possess the same active properties. The saponin constituent causes the roots to be largely used in many frontier regions as a substitute for soap. The poisonous constituent of *P. acinosa* Roxb. (*P. esculenta* Haw.; *Pircunia e.*—Moq.) has been called *phytolaccatoxin*, ($C_{24}H_{38}O_8$), and is resinous in nature.

Phytolaccaceæ.—The Pokeberry Family is regarded by Heimerl as containing 22 genera and about 70 species of plants of very diverse habits, constituents, and properties. So far as generalization regarding properties can go, it may be said that drastic properties, similar to those of Phytolacca, prevail. This is true of the Chilean plants *Pircunia littoralis* Poepp. and *Anisomeria drastica* Moq. (*Pircunia d.*—Poepp.; *P. suffruticosa* Bert.).

Petiveria alliacea L., the *Guinea-hen, Strong-man's weed*, or *Cino d'Alho*, of tropical and subtropical America, is a perennial herb, or somewhat suffrutescent, of a strong garlicky odor. It is largely used by the natives of the country where it grows for many purposes, mostly depending upon its antispasmodic properties. It is said to be diaphoretic, diuretic, emmenagogue, abortifacient, and anthelmintic. It is used to relieve toothache and, it is said, as an antidote to curare-poisoning. *P. hexaglochin* Fisch., the *Pipi-root* of Brazil, has similar properties, and *Gallesia Scorododendrum* Casar (*G. Garazema* Moq.), of Brazil, and several species of *Seguiera* are similarly used.

PICROTOXINUM, *Br.*—Picrotoxin.

Picrotoxine, Fr. Cod.; *Pikrotoxin*, G.

A neutral principle obtained from the fruits of *Anamirta paniculata*, Colebr.

Origin.—Anamirta paniculata is a tall climbing shrub, with broad heart-shaped leaves and long drooping racemes of small greenish dicœcious flowers, indigenous to India and some of the East Indian islands. The fruit is known as

Cocculus Indicus or *Fructus cocculi.*—*Fishberries*, E.; *Coque du Levant*, Fr.; *Kokkelskörner, Fischkörner*, G.—It is globoidally, kidney-shaped, about 6 Mm. ($\frac{1}{4}$ In.) in diameter and 10 Mm. ($\frac{2}{5}$ in.) in length, blackish brown, and wrinkled. The base and apex of the fruit are close together on one side of the fruit, separated from each other by a shallow sinus and connected by an obscure ridge running around the convex side. The endocarp or shell is whitish, thin, and on the narrow concave side folded inward, forming a double projection into the interior of the fruit, and causing the embryo to assume a semilunar shape upon longitudinal section. The fruit is inodorous and almost tasteless, with the exception of the shrivelled oily embryo, which is disagreeably bitter. Cocculus differs in the characters described from all other fruits usually met with in drug-stores. According to Schmidt and Rolmer (1883), the fruit contains 23.6 per cent. of fat, over one-third of which is free stearic acid. Pelletier and Couërbe (1833) isolated from the integuments of the fruit the crystalline and tasteless alkaloid *menispermine*, $C_{18}H_{24}N_2O_2$, and *paramenispermine*, which has the same composition, but differs from the former in being insoluble in ether, sublimable, and in failing to neutralize acids. These bodies are associated with the amorphous brown *hypopicrotoxic acid*, which is insoluble in ether and water. The poisonous principle, picrotoxin, is contained in the kernel, and was first isolated by Boullay in 1819. Picrotin was found in the kernel by Barth and Kretschy in 1880, and anamirtin, $C_{19}H_{26}O_{10}$, a non-poisonous principle, was also isolated by the same investigators.

FIG. 309.

Cocculus Indicus: fruit and longitudinal section.

Preparation.—Bruised cocculus indicus is exhausted by boiling alcohol, specific gravity 0.85; the tincture is concentrated by distillation to about one-third the weight of the fruit; after cooling, the fat is removed and the residue boiled with one-half its weight of water; the decoction is filtered while hot, the filtrate slightly acidulated and crystallized; the crystals require to be purified from hot alcohol. The portion insoluble in water contains menispermine, paramenispermine, and hypopicrotoxic acid.

Properties.—Picrotoxin occurs in colorless and inodorous prismatic crystals, possessing a bitter taste. It dissolves in 330 parts (150 parts, Fr. Cod.) of cold, or 35 parts (25 parts, Fr. Cod.) of boiling water, and in 13 parts (10 parts, Fr. Cod.) of cold, or 3 parts of boiling 90 per cent. alcohol. Picrotoxin melts at 192.2° C. (378° F.) (about 200° C. (392° F.), Fr. Cod.). It is soluble in 10 parts of potassium hydroxide solution, the resulting liquid immediately, on boiling, reducing Fehling's Solution. If heated on platinum foil, the crystals melt to a yellow liquid, which on further heating becomes charred, and is finally completely dissipated. Picrotoxin dissolves in sulphuric acid with a saffron-yellow color.—Br. It is soluble in acids and in alkaline solutions, without combining with these, and is precipitated from the latter solutions by carbonic acid; also soluble in amyl alcohol, benzene, and chloroform. These latter solvents extract picrotoxin from acidulated aqueous solutions, but not from alkaline solutions. The French Pharmacopœia gives the solubility in ether as 1 in $2\frac{1}{2}$, and states that nitric acid converts picrotoxin into oxalic acid. A trace of picrotoxin treated with a 20 per cent. solution of benzaldehyde in alcohol, and a drop of concentrated sulphuric acid added thereto, produces a red color, which on gentle stirring forms red streaks through the liquid (H. Meltzer, *Zeitschr. anal. Chem.*, 37, pp. 345–358).; cholesterol and physosterol give a similar color reaction. If a mixture of picrotoxin and 3 times its weight of potassium nitrate be moistened with strong sulphuric acid, and a strong solution of sodium hydroxide be then added, an intense red color will be developed.—*Langley's* reaction.

Tests.—Besides possessing the above-mentioned properties, picrotoxin should not be precipitated in aqueous solution by mercuric chloride, platinic chloride, or tannic acid, showing difference from and absence of alkaloids.

Picrotoxin by treatment with boiling benzene, by bromination, or by the action of hydrochloric acid upon its ethereal solution is readily decomposed into *picrotoxinin* and *picrotin:* $C_{30}H_{34}O_{13}$ (picrotoxin) $= C_{15}H_{16}O_6$ (picrotoxinin) $+ C_{15}H_{18}O_7$ (picrotin). R. J. Meyer and P. Bruger (*Ber.*, 1898, 31, pp. 2958–2974) assert that picrotoxin is simply a mixture of 54–55 per cent. of picrotoxinin and 45–46 per cent. of picrotin, but their evidence is by no means conclusive.

Picrotoxinin is intensely bitter and poisonous. It crystallizes from water in the cold with 1 molecule of water, becomes anhydrous at 100° C. (212° F.), soluble in about 700 parts of water at 15° C. (59° F.), readily soluble in boiling water, benzene, ether, and chloroform. It gives color reactions similar to picrotoxin, and reduces ammoniacal silver solution in the cold, and Fehling's Solution on the application of heat.

Picrotin crystallizes from aqueous solution with varying amounts of water of crystallization. It melts at 250° C. (482° F.), is soluble in about 600 parts of water at 15° C. (59° F.), has an intensely bitter taste, but is non-poisonous. It is crystallizable from water in the form of delicate white needles or thick glistening prisms, according to concentration. It reduces ammoniacal silver solution and Fehling's Solution.

Anamirtin, a minor constituent found in the mother liquors from picrotoxin, is difficultly soluble in chloroform and benzene, decomposes at 200° C. (392° F.) without previous melting, and does not reduce Fehling's or ammoniacal silver solution.

Action and Uses.—Picrotoxin is a powerful poison to all animal life. Large doses produce vomiting, salivation, accelerated respiration, a slowed pulse, and a rise in arterial pressure, followed by stupor and epileptiform convulsions, great depression, coma, and death. The convulsions are characterized by marked clonic movements which follow a period of tonic muscular contraction. They are due to irritation of the motor cells in the medulla and spinal cord. During the spasms the breathing is interrupted, but it returns during the intervals of quiet and collapse which follow. The respiratory depression gradually increases until respiration fails to return after a spasm, and death from asphyxia results. The vomiting, acceleration of respiration, and rise in blood-pressure, which appear before the onset of the convulsions, are produced by stimulation of the centres in the medulla, which respectively preside over these functions. The slow pulse is accounted for principally by the stimulation of the cardiac inhibitory centre in the medulla, and after large doses in part to direct depression of the heart muscle. The employment of the drug in internal medicine has met with little success. Recommended in the treatment of epilepsy, chorea, and paralysis, its use has not borne out the claims made for it. Cocculus Indicus, one of the drugs yielding picrotoxin, is used in tincture, decoction, or ointment to destroy lice. The dose of picrotoxin is from $\frac{1}{64}$ to $\frac{1}{20}$ grain (0.001–0.003 Gm.).

PILOCARPINÆ HYDROCHLORIDUM, *U. S.*—Pilocarpine Hydrochloride.

Pilocarpinum hydrochloricum, P. G.—*Chlorhydrate de pilocarpine*, Fr.; *Pilokarpinhydrochlorid, Salzsaures Pilokarpin*, G.

Formula, $C_{11}H_{16}N_2O_2HCl$. Molecular weight, 242.81.

The hydrochloride of an alkaloid obtained from pilocarpus. It should be kept in well-stoppered, amber-colored vials.—U. S.

Preparation.—Pilocarpine hydrochloride is made by neutralizing diluted hydrochloric acid with pure pilocarpine, concentrating the solution, and setting the same aside over sulphuric acid to crystallize. 10 parts of the free alkaloid will require about 17.5 parts of the official 10 per cent. acid.

Properties.—The salt occurs in colorless or white, transparent crystals, odorless, and having a faintly bitter taste. It contains no water of crystallization and deliquesces on exposure to damp air. It is soluble at 25° C. (77° F.) in 0.3 part of water and in 2.3 parts of alcohol; very soluble in water at 80° C. (176° F.), and in 1.1 parts of alcohol at 60° C. (140° F.); at 25° C. (77° F.) insoluble in ether and soluble in 540 parts of chloroform. After drying the salt at 100° C. (212° F.) for several hours, it melts at 195.9° C. (384.5° F.) (193°–195° C., P. G., 204°–205° C. (corr.) Jowett). Upon ignition it is entirely consumed. Its aqueous solution is neutral, or at times has a faintly acid reaction toward litmus-paper. Sulphuric acid dissolves the salt, with elimination of hydrochloric acid gas and the formation of a colorless liquid. On adding to this liquid a small fragment of potassium dichromate on a white porcelain surface a bright, grass-green color is produced. Silver nitrate test-solution produces a white precipitate insoluble in nitric acid, if added to a solution of the salt. On rubbing together equal parts of pilocarpine hydrochloride and calomel, a black color is produced.—U. S. The salt is easily obtained pure in very large crystals by crystallization from strong alcohol and has a specific rotation of + 91.74° (Jowett). "If some of the salt be

added to fuming nitric acid, a pale-green solution results. A 1 per cent. aqueous solution of the salt is not affected by addition of ammonia-water, nor of potassium dichromate solution. Sodium hydroxide solution causes turbidity only in a concentrated aqueous solution of the alkaloidal salt."—P. G. The mixture of pilocarpine hydrochloride and calomel mentioned above requires moistening with alcohol before it will blacken.

Tests.—Besides possessing the properties mentioned, pilocarpine hydrochloride should respond to the following test, which distinguishes it from all other alkaloids: "Dissolve 0.01 to 0.02 Gm. of the salt in 2 Cc. of water in a test-tube, add 2 Cc. of a solution of hydrogen peroxide (slightly acid), and carefully pour on top of the liquid a small layer of benzene; then add 3 or 4 drops of a 0.3 per cent. solution of potassium dichromate and shake gently. The benzene layer will turn violet, while the aqueous layer will remain yellow. (If more than 0.02 Gm. is used, the benzene turns blue, and the reaction is no longer characteristic.")—U. S.

Action and Uses.—Pilocarpine hydrochloride possesses the same medicinal properties as pilocarpus. In solution of 1 to 4 grains (0.06–0.25 Gm.) to the ounce (30 Cc.) of water it is used as a myotic. The dose is from $\frac{1}{8}$ to $\frac{1}{2}$ grain (0.008–0.03 Gm.) hypodermically, or $\frac{1}{4}$ to $\frac{1}{2}$ grain (0.015–0.03 Gm.) by mouth.

PILOCARPINÆ NITRAS, *U. S., Br.*—Pilocarpine Nitrate.

Azotate de pilocarpine, Fr.; *Pilocarpinnitrat*, G.

The nitrate of an alkaloid obtained from Pilocarpus, U. S.

Formula, $C_{11}H_{16}N_2O_2HNO_3$. Molecular weight, 269.20.

Preparation.—Pilocarpine nitrate may be made in a manner analogous to that suggested for the hydrochloride—namely, by neutralizing diluted nitric acid with pure pilocarpine. 121 parts of the official 10 per cent. acid will require about 40 parts of the free base. After a neutral solution has been obtained, the same is slowly evaporated to dryness, redissolved in hot alcohol (90 per cent.), and allowed to crystallize.

Properties.—The salt occurs as colorless or white shining crystals (white crystalline powder, Br.), odorless, and having a faintly bitter taste. It is permanent in the air and contains no water of crystallization. Soluble at 25° C. (77° F.) in 4 parts of water (8 or 9 parts of cold water, Br.) and in 60 parts of alcohol (slightly soluble in cold 90 per cent. alcohol, Br.); at 80° C. (176° F.) very soluble in water and at 60° C. (140° F.) soluble in 16 parts of alcohol (freely soluble in hot 90 per cent. alcohol, Br.); insoluble in ether and chloroform. It melts at 170.9° C. (339.7° F.) and is quickly consumed upon ignition, leaving no residue. The aqueous solution of the salt (1 in 100) is acid to litmus-paper. Sulphuric acid dissolves the salt without color, and on adding a fragment of potassium dichromate to the solution, a bright grass-green (emerald-green, Br.) color is produced. An aqueous solution of the salt mixed with an equal volume of ferrous sulphate test-solution, and underlaid with a layer of sulphuric acid, gives a brown ring at the juncture of the two layers. On rubbing together equal parts of the salt and of calomel, no black color is produced (difference from *pilocarpine hydrochloride*).—U. S. According to Jowett (*Trans. Chem. Soc.*, 1900), commercial pilocarpine nitrate contains variable amounts of isopilocarpine nitrate, which lowers the melting-point. The pure salt melts at 178° C. (352.4° F.), corr., and has a specific rotation of + 82.9°.

Tests.—Pilocarpine nitrate should possess the properties mentioned and correspond to the specific test mentioned under the preceding salt, which distinguishes it from all other alkaloids and is characteristic of the salts of pilocarpine.

Action and Uses.—The action and uses of pilocarpine nitrate are the same as of the hydrochloride. (See also PILOCARPUS.)

Other Salts of Pilocarpine.—Besides the hydrochloride and nitrate, the hydrobromide and salicylate of pilocarpine have also been used. They may be readily prepared by neutralizing dilute solutions of the respective acids with pilocarpine, and treating the solutions thus obtained as directed under the nitrate.

PILOCARPINE-PHENOL is a colorless oily liquid obtained by fusing a mixture of 10 parts of pilocarpine and 4.5 parts of phenol. It is soluble in water and in alcohol, and is used subcutaneously.

ESERINE-PILOCARPINE is the name applied to a crystalline powder obtained by dissolving a mixture of 1 part of physostigmine salicylate and 2 parts of pilocarpine hydrochloride and allowing the solution to crystallize.

PILOCARPUS, *U. S.*—Pilocarpus; Jaborandi.

Jaborandi Folia, Br., Fr. Cod.; *Folia Jaborandi*, P. G.

The dried leaflets of *Pilocarpus microphyllus* Stapf. (*Small-leaved* or *Maranham Jaborandi*) or of *Pilocarpus Jaborandi* Holmes (*Pernambuco Jaborandi*) (Fam. *Rutaceæ*), yielding, when assayed by the U. S. P. process, not less than 0.5 per cent. of alkaloids.

Pilocarpus is official, under that title, in nearly all pharmacopœias. The British recognizes only the second-named species; the German includes "species with imparipinnate leaves," and relies upon the description to exclude undesirable species; a number name *P. pinnatifolius* Lem., evidently regarding this name as synonymous with *P. Selloanus* Engler, an idea which is by no means well proved. The Portuguese cautions against confusing this drug with the leaves of *Monniera trifolia* Nees et Mart., of the same family (*Para Jaborandi* or *Alfacaca de Cobre do Brazil*), and with those of *Piper Jaborandi* Vell. (Fam. *Piperaceæ*).

The inclusion of Rio Jaborandi (*P. Selloanus* Engler) in the definition of our Pharmacopœia of 1890 was unquestionably ill-advised, since these leaves are very irregular and deficient in quality, sometimes almost worthless.

Origin.—These plants are good-sized shrubs. The precise regions of growth are not known, but are, not with the best of reasons, assumed to be in the general vicinity of the cities named, from which they are respectively exported. Both of the official species are commonly scarce and high-priced and others are very frequently substituted for them in commerce. All Jaborandi leaves should be collected when fully grown, after the close of the rainy season, and when of thick texture, and should be thoroughly dried before packing, as they are very subject to mustiness.

The cultivation of Jaborandi is as yet a wholly undeveloped industry, but one of great promise, in view of the requirements for a more uniform and better drug, and also considered as a financial investment. Experiments made in Italy in the cultivation of the Rio Janeiro jaborandi resulted very favorably.

FIG. 310.

Jaborandi: *A*, Pernambuco; *B*, small-leaved; *C*, Aracati; *D*, Rio; *E*, Ceara.

Description.—*P. Jaborandi:* Very shortly and stoutly petioled, the blades 6 to 12 Cm. (2½ to 5 In.) long and 2 to 4 Cm. (¾ to 1½ In.) broad, oblong or oval, occasionally a very

little narrower above or below the middle, usually slightly inequilateral at the base, blunt and retuse at the summit, entire and narrowly revolute at the margin, yellowish or brownish green, smooth and somewhat shining, especially underneath, thick and coriaceous, not much wrinkled, the reticulate venation prominent on both surfaces, especially underneath; strongly pellucid-punctate; somewhat and peculiarly aromatic when crushed and warmed in the hand; taste bitterish, somewhat salty, aromatic, later somewhat pungent and sialagogue.

P. microphyllus: Leaflets 1.2 to 3.7 Cm. (½ to 1½ In.) long and 0.8 to 1.6 Cm. (⅓ to ⅔ In.) broad; the lateral, which are about twice as numerous as the terminal, without petiolules, rhomboidally oval to obovate, acute at the base, blunt, and unequally emarginate at the summit; the terminal on short margined petiolules, almost equally oval to obovate, and rather narrower than the lateral, with which they otherwise agree; all thickish and rigid, entire at the margin, smooth, dull-green, finely pellucid-punctate; midrib stout and veins rather coarsely reticulate, lightly prominent; odor and taste similar to those of *P. Jaborandi.*

The powder of small-leaved Jaborandi is of a grayish green, that of Pernambuco yellowish green. Schneider gives the following measurements as characteristic of the elements of the powder of the two varieties, the material examined having been supplied by ourselves and thoroughly authenticated. Of the small-leaved Jaborandi the upper epidermis-cells 23 to 35 by 15 to 17 mikrons; average length of outer palisade-cells 45 mikrons; crystals few and small. The corresponding measurements for Pernambuco Jaborandi he gives as follows: upper epidermis-cells 45 to 55 by 18 to 22 mikrons; outer palisade-cells 30 to 35 mikrons; crystals, large, 30 mikrons. Geiger gives the length of hairs of the Pernambuco variety from 440 to 600 mikrons.

Adulteration.—The practice of supplying one variety for another can be stated as far more common than that of supplying the article called for. The recognition of such substitution will be considered under *Allied Species.* A few substances, not Jaborandis at all, may here be considered. The leaflets of one or more species of *Swartzia* (Fam. *Leguminosæ*), have been supplied under the name of "Maranham Jaborandi," which differ from that article notably in the presence of some small leaflets, ranging down to only ⅓ of an inch in length. These leaflets are somewhat rhomboidally ovate, upon a short hairy petiole, the upper surface shining, the lower minutely hairy on the principal veins, the finer venation pellucid, but pellucid oil-dots entirely wanting. The leaves of *Piper Jaborandi* and of some other species of Piper may be recognized by the absence of the notch at the summit, as well as of the pellucid dots. Under the name of "Jaborandi Bark," *Alcornoco Bark* (from *Bowdichia virgilioides* Kunth, Fam. *Leguminosæ*) has been offered as a substitute for Jaborandi.

Constituents.—The most important constituent of Jaborandi is the alkaloid PILOCARPINE, discovered in 1874 by Hardy. Its yield from good Pernambuco leaves ranges from a little less than 0.5 to nearly 1 per cent. In the small-leaved variety the amount is believed to average somewhat higher. The stalks, which exist in large amount in some lots of drugs, contain about half as much alkaloid as the leaves. The free base is recognized only by the French Pharmacopœia. It may be obtained by moistening the finely ground leaves with solution of sodium carbonate and extracting the same with warm benzene. The benzene solution is shaken out with diluted hydrochloric acid, and, after separation, the acid liquids are made alkaline with sodium carbonate solution and shaken out with chloroform. Upon evaporation of the chloroformic liquid the residue, consisting of crude alkaloids, is neutralized with diluted nitric acid, and the solution evaporated to dryness and purified by repeated crystallization from alcohol. Finally, the pilocarpine nitrate is dissolved in water, made alkaline with ammonia, and shaken out with chloroform. Evaporation of the chloroformic solution yields the pure alkaloid in the form of a colorless syrupy liquid. Pilocarpine is readily soluble in water, alcohol, and chloroform, but scarcely at all in ether. It possesses strong basic properties and forms readily crystallizable salts, which show more or less of an acid reaction toward litmus. In contact with potassium, sodium, or barium hydroxide, pilocarpine is converted into an acid and forms salts of the respective alkalies, from which the base may be again regenerated by acids, even carbonic acid. Regarding the other constituents, some of the conflicting statements have probably originated in the use by the analysts of different varieties of leaves. Up to 1900 it was asserted that, besides pilocarpine, 2 other alkaloids, pilocarpidine and jaborine, were present in jaborandi leaves, to which the formulas $C_{10}H_{14}N_2O_2$ and $C_{22}H_{32}N_4O_4$ were respectively assigned. The former was isolated by Harnack and described as a liquid body, differing from pilocarpine in that its aqueous solution is not precipitated by auric chloride. Jaborine was said to occur in the leaves of *Pilocarpus pinnatifolius* and also in false jaborandi (*Piper reticulatum*). It was also

said to be formed upon evaporation of acid solutions of pilocarpine, as an amorphous substance, more difficultly soluble in water than pilocarpine. H. A. D. Jowett has recently subjected the alkaloidal constituents of pilocarpus to a careful study and published the results of his investigations in *Trans. Chem. Soc.* for 1900, 1901, 1903. He has shown that a basic substance isomeric with pilocarpine is present in jaborandi leaves and that this base, which he calls isopilocarpine, is present in variable amounts in commercial pilocarpine nitrate. It was obtained as a colorless viscid oil, boiling at 261° C. (501.8° F.) under 10 millimeters pressure, and can be distilled without decomposition. Isopilocarpine can also be obtained by the action of heat or alkali on pilocarpine. Jowett was not able to obtain jaborine from either *Pilocarpus pinnatifolius* or *P. microphyllus*, and upon examination of the commercial article of that name found it to be a brown oil, which proved to be not homogeneous, but a mixture of isopilocarpine, pilocarpidine, and possibly pilocarpine, together with a little coloring-matter. Jowett states that while it is possible that such an alkaloid as jaborine may have existed in *P. Jaborandi*, it is certain that no such body exists in the jaborandi leaves at present obtainable. Furthermore, he has found that while pilocarpidine is not present in the leaves of *P. microphyllus*, it was no doubt obtained from *P. Jaborandi*, which was formerly plentiful, but has become scarce. There is also present in pilocarpus about 0.5 per cent. of a volatile oil, which has been called pilocarpene, a little resin, tannin, etc.

Jaborandine was extracted from the leaves of *Piper Jaborandi*, but there is no reason to believe in its existence in any *Pilocarpus*.

The Pharmacopœia requires that when assayed by the process which follows, pilocarpus should contain not less than 0.5 per cent. total alkaloids.

Assay of Pilocarpus.—Pilocarpus, in fine No. 60 powder, 10 Gm.; chloroform, ammonia-water, normal sulphuric acid, tenth-normal sulphuric acid, fiftieth-normal potassium hydroxide solution, cochineal or iodeosin test-solution, each, a sufficient quantity. Moisten 10 Gm. of powdered pilocarpus thoroughly with 2 Cc. of ammonia-water and sufficient chloroform to wet it well, and at once pack it firmly in a small tubular percolator, the tube of which has been firmly plugged with absorbent cotton. Percolate with chloroform containing about 2 per cent. of ammonia-water until the powder has been exhausted, for which purpose about 100 Cc. will usually suffice. Pour the percolate into a separator, and shake out with 15 Cc. of normal sulphuric acid, drawing off the acid aqueous solution into another separator, and repeating the shaking out with 2 Cc. more of normal sulphuric acid, mixed with 8 Cc. of distilled water. Add the acid solution to the second separator, and repeat the shaking out again with 10 Cc. of distilled water, adding the aqueous liquid again to the second separator. Add 20 Cc. of chloroform to the second separator, make alkaline with ammonia-water, shake well, and draw off the chloroform into a beaker. Repeat the shaking out twice with 15 Cc. and 10 Cc. of chloroform, and add the chloroform to the beaker. Evaporate off the chloroform in water-bath, and dissolve the residual alkaloids in 5 Cc. of tenth-normal sulphuric acid. Add 5 drops of cochineal or iodeosin test-solution, and titrate the excess of acid with fiftieth-normal potassium hydroxide solution. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide solution used by 5, subtract this number from 5 (the 5 Cc. of tenth-normal acid used), multiply the remainder by 0.02, and this product by 10 (or multiply at once by 0.2), which will give the percentage of total alkaloids in the drug.—U. S.

Pharmaceutical Preparations.—Fluidextract of Pilocarpus, U. S. P.; Tincture of Jaborandi, Br.

Action and Uses.—Pilocarpus and its alkaloid pilocarpine have an effect almost identical in character. Jaborine is an irritant to the stomach, and is apt to cause nausea and vomiting. The chief effect produced by pilocarpine when given to man is profuse sweating and salivation. When the sweating is not very marked, salivary flow is more than usually profuse. Small doses not sufficiently large to cause free sweating sometimes cause profuse diuresis. The profuse flow of sweat is due to the stimulating effect of the drug upon the ends of the nerves in the sweat-glands and of the sweat-glands themselves. Sometimes the drug increases the secretion of milk in nursing women.

The effect of pilocarpus in man is quite different from its influence upon animals, for in the latter its effect seems to be stimulant so far as the circulation is concerned, whereas in man it nearly always acts as a depressant.

Upon the pupil pilocarpine acts as a myotic in the strength of 1 to 4 grains to the ounce (0.06–0.25 Gm. to 30 Cc.), and is often employed in medicine for this purpose.

Medicinally, pilocarpus is used to relieve uræmia, but its use must be most cautious lest it cause pulmonary œdema. It has also been used with care in cardiac and renal dropsy. Hypodermically pilocarpine is employed to remove opacities in the vitreous humor of the eye and for the relief of thickening of the tympanic membrane. DaCosta and others have obtained good results from its use in full, repeated, hypodermic doses in erysipelas.

This drug also often acts as a powerful stimulant to the growth of the hair, whether it be applied to the scalp or taken internally, and the new growth is often very dark in hue.

Pilocarpus is the physiological antidote to atropine and agaricin.

The dose of fluidextract of pilocarpus is from 10 to 30 minims (0.60–2 Cc.). Pilocarpine hydrochloride is used in the dose of from $\frac{1}{8}$ to $\frac{1}{2}$ grain (0.008–0.03 Gm.); and the tincture of jaborandi of the B. P. is given in the dose of from 2 to 4 drachms (8–16 Cc.). The nitrate of pilocarpine is given in the same dose as the hydrochloride.

Allied Species.—There are about 15 species of *Pilocarpus* Vahl., several of them bearing leaves possessing but a single leaflet. Of the latter, only 2, *P. spicatus* A. St. Hil. and *P. racemosus* Vahl., have entered commerce as Jaborandi. The first named (Fig. 305, C) is a short, broad, thickish, dark-brown, smooth, and slightly glossy leaf, and is marketed as *Aracati Jaborandi.* The mass is coarsely stemmy and the leaves usually much folded or bent. Its powder is of a dull-brown color. The upper epidermal cells measure 18 to 30 mikrons broad, the lower about the same, the outer palisade-cells 45 to 70 mikrons long, the crystals few and small. It is said (Paul and Cownley) to contain 0.16 per cent. of alkaloid, having a melting-point of 151.5° C. *P. racemosus* is a West Indian species, the leaf large and thin and somewhat resembling the Rio. Its histology and powder have not been investigated. Rocher reports it as containing 1 per cent. of alkaloid, of which two-thirds is pilocarpine, the remainder jaborine. If this were correct, it would be one of the best of all the Jaborandis, but the statement has recently been positively denied. Of the unofficial species possessing leaves with 3 or more leaflets, the most important, pharmaceutically and commercially, is the Rio Janeiro variety (Fig. 305, D), produced by *P. Selloanus*, or *P. pinnatifolius* Lem., according to different views. This variety so closely resembles the Pernambuco as to be most readily mistaken for it, and it is very largely supplied under that name. It is almost as long, but is relatively narrower, and is much more inclined toward the oblanceolate form. It is little inclined toward the yellow tinge of the Pernambuco (Fig. 305, A), unless over-mature, but is of a dull green. It is far less thick and tough, and less prominently veiny. Its powder is green to slightly grayish green. Schneider gives it the following characters: upper epidermal cells 21 to 33 by 13 to 15 mikrons; average length of outer palisade-cells 45 mikrons; crystals numerous, small.

Paraguay Jaborandi is by many considered specifically identical with the preceding, a view which we do not share. It is narrower, thinner, less tough and veiny, and of a duller green than the Rio. Both, but especially the latter, are poor in pilocarpine.

P. trachylophus Holmes has 5 leaflets (Fig. 305, E). It is well distinguished by its very peculiar dark and somewhat smudgy brown-green color, its thickish texture, strongly revolute margin, and densely hairy lower surface. It is not to be mistaken for the yellowish-green leaves with a yellowish velvety lower surface occasionally found mixed with the Pernambuco leaves and of similar form and size with the latter. It is commercially known as *Ceara Jaborandi.* It yields a dark-green powder. Its upper epidermal cells are from 30 to 40 mikrons broad, the lower somewhat smaller, the outer palisade-cells about 100 mikrons long, the crystals few and small, the hairs very abundant, about 300 mikrons long. Paul and Cownley found it to contain 0.4 per cent. of alkaloid, but of a very different character from that of pilocarpine. This variety is quite abundant in commerce.

The above are the only species which have as yet reached any commercial importance, but there is little doubt that others will do so.

PILULÆ.—Pills.

Pilules, Fr.; *Pillen*, G.

Pills are a very convenient mode of administering medicines, the chief advantage lying in the small bulk to which the medicine is reduced and in the almost complete disguise of bitter and nauseous remedies by reason of their being swallowed without previous mastication. Pills are admirably adapted for the administration of heavy metallic substances not readily suspended in liquids, and also in cases where the action of the medicine is to be slow, or even retarded until it reaches the lower bowel. The usual shape given to pills is that of a sphere or globe, although an ovoid shape is also sometimes resorted to, and in a few cases even the lenticular shape is preferred. Their

weight ranges from less than 1 to 5 grains (0.06–0.3 Gm.) for vegetable substances, or about 8 or 10 grains (0.5 or 0.6 Gm.) for heavy mineral compounds; if a pill exceeds this weight, it is called a *bolus*. Boluses are occasionally made weighing 20 or 30 grains (1.3 or 2.0 Gm.) each, and are often of a softer consistence than pills. Very small pills coated with sugar are called *granules*.

Preparation.—The most important step in the preparation of pills is the formation of a proper mass, which should consist of a firm, consistent paste, sufficiently plastic to admit of being molded without adhering to the molds, and sufficiently firm to prevent the pills from losing their original shape. Plasticity is that peculiar condition where adhesiveness and firmness are properly balanced: the former of these properties is due to a partial softness, which enables the particles of the mass to adhere to each other, thus imparting tenacity to the whole. Some substances possess this adhesiveness in themselves, but require the addition of a liquid—water or alcohol—in order to develop it, as, for instance, gums and resinous drugs. Other substances possess no inherent adhesive properties, and in such cases it becomes necessary to impart tenacity to them by the addition of some liquid or solid material, called the excipient; such substances are camphor, calomel, bismuth salts, some saline or vegetable powders, reduced iron, and the like. Firmness in a pill-mass is as essential as adhesiveness, and, while the latter is brought about by a state of partial solution or fluidity, so, inversely, the insolubility of some particles is necessary for the required firmness. The addition of excipients must be made judiciously, so that the constituents of the mass be not modified in their action nor the bulk be unnecessarily increased; and after each addition the mass should be well kneaded, which, itself having a softening influence on the mass by reason of the heat generated, enables the operator to judge of the true condition of the mixture. Whenever possible all constituents of a pill-mass should be reduced to very fine powder before the addition of any excipient, as only in this condition can the homogeneity of the mass be assured, as also the subsequent accurate division of doses. Small quantities of potent remedies, such as alkaloids, narcotic extracts, toxic chemicals, etc., are preferably triturated with a little sugar of milk before mixing them with the other ingredients, to facilitate uniform distribution.

For the proper incorporation of volatile oils in pill-masses powdered soap is to be preferred, which completely emulsionizes the oil and prevents its separation during the subsequent manipulations; soap, however, should never be employed in pill-masses containing heavy metallic salts, such as iron, lead, etc., as decomposition will take place and cause the mass to crumble: in such cases the addition of an absorbent powder is preferable. As an absorbent for large quantities of volatile oils or as an excipient for heavy metallic salts or troublesome combinations, such as capsicum, lead acetate, and extract of hyoscyamus, and the like, the powder suggested some years ago by Mr. Mattison will be found very serviceable: it consists of 1 part of powdered tragacanth and 7 parts of finely powdered (No. 80) elm-bark; and the following quantities will be found sufficient for making a good pill-mass with the aid of a little syrup: 3 grains of the powder for 60 grains of iron by hydrogen, or bismuth subnitrate, or calomel, or equal parts of camphor and extract of henbane, or equal parts of camphor and lead acetate; 6 grains of the powder for 60 grains of dried ferrous sulphate or scale salts of iron, or equal parts of camphor and capsicum, etc. As an absorbent for soft masses, or such as contain large amounts of extracts, powdered liquorice-root will be found a better drying agent than marshmallow-root or elm-bark, and less likely to increase the bulk, as it contains little or no mucilaginous matter. For creosote soap may be used if in combination with other drugs, but if prescribed alone, powdered liquorice-root or the mixture of tragacanth and elm-powder with syrup will be found to answer well: 2 or 3 grains of the powder should be used for each drop of creosote. For tar, Peru balsam, and similar substances, clay (kaolin or fuller's earth) will be found a good absorbent, the mass to be made with soap. For the salts of quinine, glycerin and acacia or tragacanth, or even glycerite of starch, will be found desirable excipients; for cinchonidine or its sulphate, however, honey with a little acacia will be found preferable to glycerin. Diluted alcohol and soap and water are the best excipients for gum-resins, such as asafetida or galbanum, and even for powders like aloes, as is shown in the Pharmacopœia. Although the use of wax has at times been recommended for pill-masses containing volatile oils, balsams, etc., we think it should only be employed in extreme cases, as pills made with wax freqently fail to give up the active ingredients in the liquids of the stomach or bowels, owing to their higher melting-

point. For pills of readily reducible substances, as potassium permanganate, silver nitrate, silver oxide, gold chloride, etc., all contact with organic matter should be avoided, and hence the best excipients would be white clay and water, which form a plastic mass, but require quick manipulation, as it soon becomes crumbly; a better excipient is a mixture of equal parts of kaolin, soft petrolatum, and paraffin, which forms a mass that readily gives up the active constituent, at the temperature of the body, in the presence of moisture. Potassium permanganate can be readily formed into a pill-mass by triturating with one-half its weight of kaolin, and then adding one-sixth or one-fourth its weight of petrolatum.

Pills containing free iodine should invariably be made with the addition of starch, so as to combine with the iodine and prevent its irritating effect on the mouth and throat; the union is very feeble, and the iodine will be readily liberated by the warm liquids of the stomach.

When deliquescent substances are ordered in pill form or such as are slowly volatilized upon exposure to air, a mixture of potassium borotartrate with half its weight of water will prove a good excipient: about one-sixth of a grain of powdered tragacanth should be added to each pill, and the mass must be quickly formed and rolled out. 60 grains of chloral hydrate or 30 grains of potassium iodide require 2 drops of the excipient. Such pills, if they are to be kept on hand for some time, require a protective coating.

It is obvious, from the foregoing, that there can not be an excipient which would be alike serviceable for all medicinal substances, or even for all drugs, capable of being reduced to powder. The choice of the excipient is very frequently left to the pharmacist, and involves a knowledge not only of the constituents of the drugs, but also of the reactions which may take place between the different ingredients in the presence of moisture. *Mucilage of acacia* or of *tragacanth* serves a good purpose if the pills are to be used in a short time, but if kept on hand they become hard and dissolve very slowly. This may be prevented by replacing about one-half or more of the water with *glycerin*. The *glycerite of starch* (see p. 728) and various combinations of it with gum-arabic, tragacanth, and sugar have been used for the same purpose. Commercial syrupy *glucose*, *manna*, the official *pill-masses*, most of the official *confections*, and more particularly those of rose, of hips, and of senna, will render powders adhesive, and if *extracts* are not inadmissible they will be found to yield good pill-masses with a comparatively large amount of powder; a rather soft extract is capable of serving as an excipient for its own weight of vegetable powder and three or four times its weight of resins and insoluble salts, and with the addition of a little syrup or honey twice the weight indicated may be incorporated.

As a rule, it will be found desirable for the physician to order some adhesive material, like extracts, together with the other ingredients of pills, but the former should not be in excessive quantities, so as not to require the addition of inert absorbent powder. When no excipient is directed, the pharmacist should select one which is simple in composition, does not increase the bulk of the mass, and is not liable to become very hard. When resinous extracts and similar materials are ordered, an excipient is not often required, but the powders may be triturated together in a warm mortar and the plastic mass rolled out into pills while still warm. The compound cathartic pills furnish an example of this kind.

Pill-masses should always be made in a Wedgewood or iron mortar, except in the case of very simple combinations, for trituration by means of a pestle is essential to produce a uniform mixture of the ingredients, and it will be found that a mass can be formed in less time and with less excipient and labor in the mortar than on the pill-tile. After the mass has been properly prepared, it is transferred to a regular pill-machine or graduated glass or porcelain tile to be rolled out, by means of a flat piece of hard wood (Fig. 316), into a cylinder of uniform thickness, which is then divided into the requisite number of pieces.

A small number of pills may be conveniently divided on a pill-tile (Fig. 315), but for a larger number a pill-machine will be found preferable, particularly if the weight of the pills corresponds to the size of the grooves, for then the perfect rounding of the pills can be readily effected by continued rolling in these grooves. In order to insure greater uniformity in cutting the mass on a pill-tile into the required number of parts, use may be made of either of the two devices shown in Figs. 311 and 312. The Liv-

ingston pill-cutter may be used to cut 24 parts at one time by simply pressing the steel cutters into the pill-mass after the same has been rolled out to the required length by

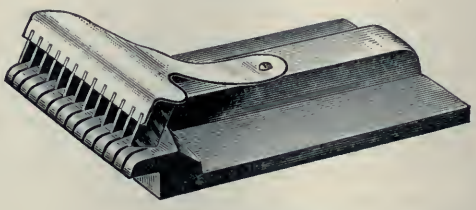
Fig. 311.

Livingston pill-cutter.

means of a wooden pill-paddle; the separate pieces may then be quickly ejected by means of a slotted metallic strip operated by a spring on the top of the bar. The Diamond pill-cutter is combined with a flat wooden roller for rolling the mass out to the required length, which is then brought under the projecting cross-piece and the metal cutters pressed down upon it; as the metal plate, to which the cutters are attached, rebounds to its original position, the latter are stripped of any adhering pieces of mass by the projecting cross-piece, through the slots of which the cutters pass.

The best pill-machine is the "Cooper patent" (Fig. 313), the woodwork being of mahogany and the metallic parts of brass. This machine has two sets of reversible grooved plates, on which four different sizes of pills can be made—1, 2, 3, and 5 grains; the plates being quickly removable and adjustable. The sides of the rolling-board are so constructed that they can be raised or lowered by means of winged screws, which

Fig. 312.

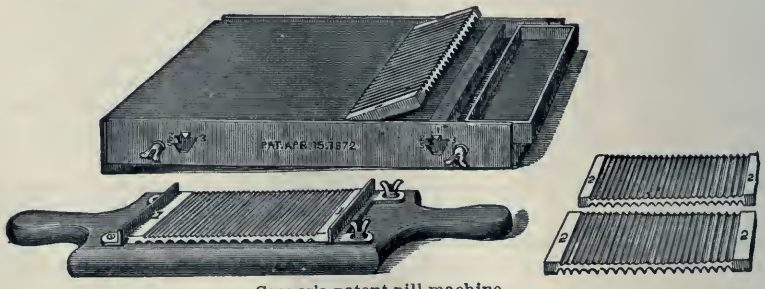


Diamond pill-cutter.

allows the mass to be rolled just the thickness required for each respective size of pill, thereby insuring always the full number of perfectly round pills.

After the mass has been properly rolled out to the length of the desired number of pills, it is laid upon the grooved plate of the board, and divided by placing the other cutter over it and drawing the same forward and backward with slight pressure.

Fig. 313.



Cooper's patent pill-machine.

When the pill-mass has been divided on a pill-tile, and also when the pills are larger or smaller than the grooves of the machine, it becomes necessary to impart a spherical shape to the pieces, by appropriate rolling between the thumb and first and second fingers, after which the pills should be placed under a pill-finisher and completely rounded by rotary motion of the same with some pressure. It is better to move the finisher about in curvilinear figures like the figure 8, instead of giving it a constant circular motion, so that the pressure may be uniform at all points. Pill-finishers usually consist of a circular piece of hard wood, with a smooth rolling surface and a projecting margin for

the purpose of confining the pills; several sizes are required to suit different sizes of pills. Fig. 314 represents a convenient pill-finisher suitable for two different sizes, as the upper and lower margins project to different lengths.

Fig. 314.

Hard-wood pill-finisher.

Pill-tile, graduated.

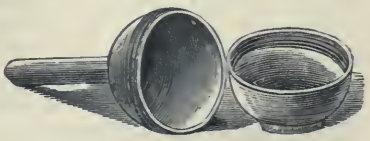
Fig. 316.

Pill-roller.

Pill-dusting.—The pill-mass, being plastic and adhesive, is apt to adhere to the slab and the fingers while being rolled out and shaped into pills. This is prevented by the use of a fine powder, which should be strictly inert unless otherwise directed by the physician. Among the most suitable powders are lycopodium, liquorice-root, and starch; the former is particularly desirable on account of its fineness and uniformity, its slight adhesiveness, and its utter tastelessness. Powdered starch should be used with all white pill-masses, Bermuda arrow-root being the best for the purpose. Only in exceptional cases is the addition of dusting-powder to the pills in the box justifiable: the pills should receive a sufficient coating of the powder under the finisher, and if the mass has been properly made there is no danger of the pills adhering, and hence there is no occasion for putting an excess of powder in the box. Magnesia and magnesium carbonate should be used with due care on account of the possible chemical effect upon the ingredients of the pills. Powdered talc (soapstone) is likewise serviceable, and has the advantage of imparting a very thin opaque and tasteless coating to the pills without impairing their solubility in the stomach; it is particularly suited for pills of silver nitrate and the like. When asafetida or other substances of a nauseous odor are given in the form of a pill, the odor may either be entirely covered or considerably modified by the use of powdered cinnamon, aromatic powder, ginger, or a similar powder.

Pill-coating.—If the pill-mass be not too soft, the amount of powder adhering to the surface of the finished pill is quite small, though generally sufficient, if quickly swallowed, to cover the taste of bitter and nauseous ingredients. More perfect coverings may be obtained in various ways, an ordinary rather deep pill-box being used, or preferably an apparatus made of hard wood consisting of two hollow hemispheres, to one of which a short handle is attached. For *silvering* or *gilding* the pills are made firm, if possible rolled out and shaped without using any powder, and after a perfectly smooth surface has been obtained they are slightly dampened and introduced into the apparatus, together with the requisite quantity of gold- or silver-leaf; after a rapid rotary motion for a few seconds the pill will be found uniformly coated with the thin metal. Glycerin should not be used as an excipient or only in a very small quantity, as it lessens the brightness of this kind of coating.

Fig. 317.



Apparatus for coating pills.

Sugar-coating is a process which is not readily applicable to the operations of the pharmacist, requiring experience and practice to insure success. It partakes of the confectioner's art, although the coating of pills with sugar requires somewhat more care, on account of the absence of starch or flour, which generally makes up a part of the confectioner's coating. Sugar-coating of pills on a large scale is done in hemispherical copper pans made to revolve slowly within a coil of steam-pipe supplying the necessary

heat for evaporation of the moisture; the pills, which should be well air-dried, are placed in the pan, and a quantity of simple syrup or of a mixture of syrup and mucilage of acacia is poured on, the pan being kept in constant rotary motion until the pills are dry. The addition of syrup is repeated until a sufficiently thick coating has been deposited on the pills, and this can be determined only by experience.

Sugar-coating can be more successfully performed with a large quantity of pills than with a small number, as the deposit of sugar takes place more uniformly, and the mutual attrition of many pills insures a smooth surface. For small operations it will be found desirable to dampen the pills with diluted mucilage of acacia or egg-albumen and then rotate them in a tinned-copper or porcelain dish containing either finely bolted sugar or a mixture of acacia 1 part and sugar 5 parts, or of sugar 2 parts, sugar of milk 1 part, and purified talcum 1 part. With care and practice fair results may be obtained, although the pills should not be expected to look so perfect as those coated by machinery.

In France sugar-coated pills are called *dragées*, and when of very small size, *granules*.

Gelatin-coating is more readily applied than sugar-coating, but, like the latter, requires practice to insure proficiency. The chief difficulty lies in the drying of the coating after the pills have been dipped into the solution of gelatin; the pills must be kept in motion while the gelatin cools, otherwise the coating will not be uniform. Pills to be gelatin-coated must be firm, dry, and free from dusting-powder; if glycerin is used as an excipient, it is likely to soften the gelatin-coating, causing the pills to stick together. For pills containing strongly odorous substances, such as asafetida, sumbul, iodoform, the valerianates, etc., gelatin-coating is decidedly inferior to sugar-coating, as the odor penetrates gelatin far more rapidly than sugar. The manner of coating the pills on a large scale is identical with that used for only a dozen pills, namely, the pills are impaled upon long, thin needles, to the depth of about $\frac{1}{16}$ of an inch, and then immersed in a solution of gelatin kept fluid by means of a water-bath; in order to avoid contraction and cracking of the gelatin upon cooling, mucilage of acacia is usually added to the solution, and, by some, syrup also. The rapid drying on a large scale is effected by placing the pills soon after they have been dipped, while still on the needles, in specially constructed drying cases connected with an exhaust fan, by means of which air is rapidly drawn through the cases, and the moisture is thus removed.

The application of a continuous coating of gelatin to pills without the use of needles is in successful operation at several large manufacturing establishments, but is not available at the dispensing counter, since extensive steam-power machinery is necessary for the work.

In place of gelatin-coating at the dispensing counter, the plan prevails in this country of disguising the disagreeable odor and taste of pills by enclosing them in gelatin capsules. These gelatin capsules are sold under the name of *empty capsules*, and consist of small cylinders closed at one end and provided with a shorter cylindrical cover; they occur in 7 sizes, ranging from $\frac{3}{8}$ inch to 1 inch in length, and are numbered respectively from No. 5 to No. 00; they are sold at fabulously low prices. The composition of the empty capsules made in this country is a mixture of gelatin and glycerin in variable proportions, dependent upon the character of the gelatin.

Pills are occasionally coated with tolu or collodion: the former coating is directed officially for the pills of phosphorus and those of iodide of iron. Instead of using the pharmacopœial solution of tolu in ether, the following, suggested by Prof. Patch, will be found to give better results: 540 grains of balsam of tolu, 180 grains of mastiche, 2 fluidounces of alcohol; dissolve and filter. Coat the interior of two flat evaporating dishes with a thin film of oil of sweet almond or petrolatum; place the pills in one of the dishes, and add a few drops of the solution; cover with the second dish, and rotate rapidly until the pills are coated, then put on a tray to dry.

The so-called "pearl-coating" is applied in a manner similar to that used for gilding or silvering; the pills, having been evenly dampened with a very thin adhesive liquid (mucilage of acacia 1 drachm, syrup 1 drachm, and water 6 drachms, or tragacanth 4 grains, syrup $\frac{1}{2}$ drachm, and water $7\frac{1}{2}$ drachms), are rotated in a globular box with purified talcum or a mixture of talcum and sugar in the form of an impalpable powder. If a high polish is desired, this can be obtained by rotating them afterward in another globe coated on the inside with paraffin.

Keratin coating has been especially recommended for pills which are not to be acted upon in the stomach, but to be dissolved in the intestinal fluids. Keratinized pills were first introduced by Dr. Unna, of Germany, but have not met with much favor, on account of the tedious process of coating. Keratin is a constituent of all horny matter, and is obtained from the same, after removal of fat with ether, by digestion, in the form of shavings or turnings with a mixture of pepsin, hydrochloric acid, and water, for 24 or 36 hours: this treatment removes all matter soluble in the gastric juice. The residue, having been well washed with water, is digested with 8 or 10 times its weight of 5 per cent. ammonia-water in a loosely stoppered flask, at a moderate heat, until a nearly complete solution results, which is then filtered and evaporated to dryness. Keratin, as thus prepared, is a commercial article; both acid and alkaline solutions of it are used for coating pills.

Ammoniacal solution of keratin is prepared by dissolving 7 parts of keratin in a mixture of 50 parts of 10 per cent. ammonia-water and 50 parts of 60 per cent. alcohol (solution may be facilitated by warming). This alkaline solution should be used for pills containing trypsin, pancreatin, metallic sulphides, etc.

Acetic solution of keratin, made by dissolving 7 parts of keratin in 100 parts of glacial acetic acid (if necessary, by the aid of moderate heat), is adapted for pills containing ferric chloride, tannin, salicylic acid, arsenic, creosote, and the salts of mercury, gold, and silver.

For chemically indifferent substances, either the alkaline or acid solution of keratin may be employed.

All pills intended to be coated with keratin must be made with some fatty excipient and contain no appreciable moisture; the mass is best made with cacao-butter and oil of sweet almond, or a mixture of purified mutton-tallow or cacao-butter 10 parts, and white or yellow wax 1 part. After the pills have been rounded they should be dipped in melted cacao-butter, which is allowed to harden; they are then placed in a porcelain dish, the keratin solution added (about 30 to 40 drops for 100 pills of medium size), and rotated until the pills have become thoroughly moistened, after which they are dried on parchment paper, to which they will not adhere. The application of keratin solution must be repeated three or four times and allowed to dry each time.

To avoid the tediousness of coating with keratin, salol coating has been recommended, which is best applied by melting salol in a dish and dipping the pills, fixed on needles, into it, afterward closing the small needle-holes separately. Salol, like keratin, is insoluble in the gastric juice, but the coating has not been found so satisfactory.

Preservation.—Uncoated pills are best preserved in lycopodium or other powder, and in a vessel which does not prevent the exchange of air. Moist pills kept in well-closed vessels are apt to become mouldy.

It should be mentioned that the British Pharmacopœia directs only *pill-masses*, leaving the final division to be specially ordered by the physician. The U. S. Pharmacopœia, on the other hand, besides recognizing two pill-masses, directs *pills* of a certain weight; for convenience of dispensing, however, the mass of some of these is sometimes kept on hand undivided.

PILULÆ ALOES, *U. S.*—Pills of Aloes.

Pilula Aloes Barbadensis.—Pill of Barbadoes Aloes; Pilula Aloes Socotrinæ.—Pill of Socotrine Aloes, Br.; *Pilules d'aloès et de savon*, Fr. Cod.—*Pilules aloétiques savonneuses*, Fr.; *Aloepillen*, G.

Preparations.—Purified aloes, in fine powder, 13 Gm.; soap, in fine powder, 13 Gm., to make 100 pills. Beat them together with water, so as to form a mass, and divide it into 100 pills.—U. S. For 12 pills use aloes and soap, of each 24 grains (1.55 Gm.).

Pill of Barbadoes aloes is made by forming a mass out of Barbadoes aloes, in powder, 2 ounces; hard soap, in powder, 1 ounce; oil of caraway 1 fluidrachm, and confection of roses 1 ounce.—Br.

Pill of Socotrine aloes is made exactly like the preceding, except that Socotrine aloes is used in place of the Barbadoes, and volatile oil of nutmeg in place of the oil of caraway.

The French Pharmacopœia also recognizes simple pills of aloes under the name of

Pilules Aloès Simples, which are made by mixing Cape aloes (10 Gm.) with sufficient honey to make a mass and dividing this into 100 pills.

Uses.—Dose, 1 to 3 pills at bedtime, for constipation.

PILULA ALOES ET ASAFŒTIDÆ, *Br.*—Pill of Aloes and Asafetida.

Pilules d'aloès et asefétide, Fr.; *Aloe- und Asafœtidapillen*, G.

Preparation.—Take of Socotrine aloes, in powder, asafetida, hard soap, in powder, confection of roses, each 1 ounce. Mix to form a mass.—Br.

Uses.—These pills may take the place of the simple aloetic pill in cases of constipation attended with flatulence, and especially in nervous or hysterical persons. Dose, 2 to 5 pills.

PILULÆ ALOES ET FERRI, *U. S., Br.*—Pills of Aloes and Iron.

Pilulæ aloëticæ ferratæ, P. G.; *Pilulæ Italicæ nigræ.—Pilules d'aloès et de fer*, Fr.; *Eisenhaltige Aloepillen, Italienishe Pillen*, G.

Preparation.—Purified aloes, in fine powder, 7 Gm.; exsiccated ferrous sulphate 7 Gm.; aromatic powder 7 Gm.; confection of rose a sufficient quantity to make 100 pills. Beat the powders together with confection of rose so as to form a mass, and divide it into 100 pills.—U. S. For 12 pills use aloes, exsiccated sulphate of iron, and aromatic powder, of each 13 grains (0.84 Gm.).

Exsiccated ferrous sulphate 1 ounce; Barbadoes aloes, in powder, 2 ounces; compound powder of cinnamon 3 ounces; syrup of glucose 3 ounces, or a sufficient quantity. Mix to form a mass.—Br.

Exsiccated sulphate of iron and powdered aloes equal parts; mix, form a mass with spirit of soap, and divide into pills, each weighing 0.10 Gm. Moisten the pills with tincture of aloes to make the surface black and glossy.—P. G.

Uses.—This combination is of value in amenorrhœa due to anæmia associated with constipation. The aloes aids the absorption of the iron and counteracts its constipating tendency. Dose, 1 to 3 pills.

PILULÆ ALOES ET MASTICHES, *U. S.*—Pills of Aloes and Mastic.

Lady Webster's dinner pills, E.; *Pilules d'aloès et de mastic*, Fr.; *Aloe- und Mastix-Pillen*, G.

Preparation.—Purified aloes, in fine powder, 13 Gm.; mastic, in fine powder, 4 Gm.; red rose, in fine powder, 3 Gm.; to make 100 pills. Beat them together with diluted alcohol so as to form a mass, and divide it into 100 pills.—U. S. For 12 pills use aloes 24 grains (1.56 Gm.), mastic 7½ grains (0.48 Gm.), and red rose 5½ grains (0.36 Gm.).

Uses.—The addition of mastic in this pill retards the solution of the aloes in the small intestine, thereby increasing the action of the latter drug in the large bowel. These pills are used as a laxative and are to be taken before or after the principal meal or at bedtime. Dose, 1 to 3 pills.

PILULÆ ALOES ET MYRRHÆ, *U. S., Br.*—Pills of Aloes and Myrrh.

Rufus's pills, E.; *Pilules d'aloès et myrrhe, Pilules de Rufus*, Fr.; *Rufussche Pillen*, G.

Preparation.—Purified aloes, in fine powder, 13 Gm.; myrrh, in fine powder, 6 Gm.; aromatic powder 4 Gm.; syrup a sufficient quantity; to make 100 pills. Beat them together so as to form a mass, and divide it into 100 pills.—U. S. For 12 pills use aloes 24 grains (1.56 Gm.), myrrh 12 grains (0.72 Gm.), and aromatic powder 8 grains (0.48 Gm.).

Socotrine aloes, in powder, 2 ounces; myrrh, in powder, 1 ounce; syrup of glucose 1½ ounces, or a sufficient quantity. Mix to form a mass.—Br.

Uses.—This pill is useful in constipation attended with flatulence. The myrrh is supposed to enhance the value of the aloes in the treatment of amenorrhœa and uterine catarrh. The dose is from 3 to 6 pills.

PILULÆ ASAFŒTIDÆ, *U. S.*—Pills of Asafetida.

Pilule d'asefétide, Fr.; *Asafœtidapillen*, G.

Preparation.—Asafetida 20 Gm.; soap, in fine powder, 6 Gm.; to make 100 pills. Beat them together with water so as to form a mass, and divide it into 100 pills.—U. S. For 12 pills use asafetida 36 grains (2.40 Gm.), and soap 12 grains (0.72 Gm.).

Uses.—These pills, each containing 3 grains (0.20 Gm.) of asafetida, present a convenient form of administering the drug. Dose, 1 to 3 pills.

PILULA CAMBOGIÆ COMPOSITA, *Br.*—Compound Pill of Gamboge.

Pilules de gomme-gutte composées, Fr.; *Gummiguttpillenmasse*, G.

Preparation.—Take of gamboge, in powder, Barbadoes aloes, in powder, compound powder of cinnamon, each 1 ounce; hard soap, in powder, 2 ounces; syrup of glucose, 1 ounce, or a sufficient quantity. Mix to form a mass.—Br.

Uses.—This is an efficient purgative in the dose of from 5 to 10 grains (0.30–0.60 Gm.).

PILULÆ CATHARTICÆ COMPOSITÆ, *U. S.*—Compound Cathartic Pills.

Antibilious pills, E.; *Pilules cathartiques composées*, Fr.; *Abführpillen*, G.

Preparation.—Compound extract of colocynth, 80 Gm.; resin of jalap, 20 Gm.; mild mercurous chloride, 60 Gm.; gamboge, in fine powder, 15 Gm.; to make 1000 pills. Mix the powders intimately; then gradually incorporate them with sufficient diluted alcohol to form a mass, and divide it into 1000 pills.—U. S. For 12 pills use compound extract of colocynth, 15 grains (0.975 Gm.); resin of jalap, 4 grains (0.260 Gm.); calomel, 12 grains (0.780 Gm.); gamboge, 3 grains (0.195 Gm.).

In making this pill-mass it is advisable to use a warm mortar and add very little water; while still warm it may be formed into pills which will better retain their shape than if made with more water at the ordinary temperature. The composition of these pills is almost exactly the same as in the previous Pharmacopœia, a lesser quantity of resin of jalap having been substituted for the extract.

Uses.—It is a well-recognized fact that a combination of purgatives, each in a small dose, produces a more uniform and thorough result with less irritation and discomfort than a large dose of any one of its component ingredients given alone. The combination of cathartics represented in this pill probably operates upon the entire intestinal tract, producing bilious stools, usually attended with little or no griping or gastric disturbance. It can be employed in nearly all cases requiring thorough purgation, and is of particular value in those conditions resulting from a torpid liver or congested portal circulation. Each pill weighs about 3 grains (0.20 Gm.). One pill is the usual laxative dose; 3 pills produce active catharsis.

PILULÆ CATHARTICÆ VEGETABILES, *U. S.*—Vegetable Cathartic Pills.

Pilules cathartiques végétables, Fr.; *Vegetabilische Abführpillen*, G.

Preparation.—Compound extract of colocynth, 60 Gm.; extract of hyoscyamus, 30 Gm.; resin of jalap, 20 Gm.; extract of leptandra, 15 Gm.; resin of podophyllum, 15 Gm.; oil of peppermint, 8 Cc.; diluted alcohol, a sufficient quantity to make 1000 pills. Mix the compound extract of colocynth intimately with the resin of podophyllum, resin of jalap, and extract of leptandra, and incorporate the oil of peppermint. Rub the extract of hyoscyamus with enough diluted alcohol to render it plastic; then beat it together with the mixture first prepared, using a sufficient quantity of diluted alcohol so as to form a mass to be divided into 1000 pills.—U. S.

For 12 pills use compound extract of colocynth, 12 grains (0.780 Gm.); extract of hyoscyamus, 6 grains (0.390 Gm.); resin of jalap, 4 grains (0.260 Gm.); extract of leptandra and resin of podophyllum, of each 3 grains (0.195 Gm.); oil of peppermint, 3 drops.

Uses.—This pill is employed for the same purpose as the compound cathartic pill. It is, however, probably less effective, and certainly not as generally used as the pill containing calomel. The dose is 1 pill as a laxative and 3 pills as a cathartic.

PILULA COLOCYNTHIDIS COMPOSITA, *Br.*—Compound Pill of Colocynth.

Pilules de coloquinte composées, Fr. Cod.—*Pilules cochées mineures*, Fr.; *Zusammengesetzte Koloquintenpillen*, G.

Preparation.—Colocynth pulp, in powder, 1 ounce; Barbadoes aloes, in powder, 2 ounces; scammony resin, in powder, 2 ounces; potassium sulphate, in very fine powder, ¼ ounce; oil of cloves, 2 fluidrachms; distilled water, a sufficient quantity. Triturate the oil of cloves with the potassium sulphate; add the colocynth pulp; mix; add the Barbadoes aloes and scammony resin; after mixing intimately add the distilled water and beat to form a mass.—Br.

The formula of the French Codex directs colocynth, aloes, and scammony, of each 10 Gm., oil of cloves, 0.05 Gm., and honey sufficient to make a mass to be divided into 200 pills.

Uses.—This is an active cathartic mass, given in the dose of from 5 to 10 grains (0.30–0.60 Gm.).

PILULA COLOCYNTHIDIS ET HYOSCYAMI, *Br.*—Pill of Colocynth and Hyoscyamus.

Pilules de coloquinte et d'extrait de jusquiame, Fr.; *Koloquinten-Bilsenkrautpillenmasse*, G.

Preparation.—Take of compound pill of colocynth, 2 ounces; extract of hyoscyamus, 1 ounce. Beat them into a uniform mass.—Br.

Uses.—The extract of hyoscyamus is added to this purgative combination to prevent griping. The dose is from 5 to 10 grains (0.30–0.60 Gm.).

PILULÆ CREOSOTI, *P. G.*—Pills of Creosote.

Pilules de Créosote, Fr. Cod.; *Kreosotpillen*, G.

Preparation.—Creosote, 10 parts; glycyrrhiza, in fine powder, 19 parts; glycerin, 1 part. Mix to form a mass, to be divided into pills weighing 0.15 Gm. each. Coat with powdered cinnamon.—P. G.

Each pill contains 0.05 Gm. of creosote.

Creosote pills of the French Pharmacopœia are of double the strength of the preceding, containing 0.10 Gm. of creosote each, and are made with dried almond soap.

Uses.—This pill presents a convenient form of administering creosote. Dose, 1 to 5 pills.

PILULÆ FERRI CARBONATIS, *U. S.*—Pills of Ferrous Carbonate.

Pilula ferri—Iron pill, Br.; *Pilules ferrugineuses de Blaud*, Fr. Cod.; *Pilulæ ferri carbonici Blaudii*, P. G.—*Ferruginous pills, Chalybeate pills, Blaud's pills*, E.; *Pilules chalybés de Blaud*, Fr.; *Blaudsche Pillen*, G.

Preparation.—Ferrous sulphate, in clear crystals, 16 Gm.; potassium carbonate, 8 Gm.; sugar, 4 Gm.; tragacanth, in fine powder, 1 Gm.; althæa, in No. 60 powder, 1 Gm.; glycerin, water, each a sufficient quantity to make 100 pills. Rub the potassium carbonate in a mortar, with a sufficient quantity (about 10 drops of each) of glycerin and water, then add the ferrous sulphate and sugar, previously triturated together to a uniform powder, and beat the mass thoroughly until it assumes a greenish color. When the reaction appears to have terminated, incorporate the tragacanth and althæa, and, if necessary, add a little more water, so as to obtain a mass of pilular consistence. Divide this into 100 pills. These pills should be freshly prepared when wanted.—U. S.

For 12 pills use ferrous sulphate crystals, 30 grains (1.920 Gm.); potassium carbonate, 15 grains (0.960 Gm.); sugar, 7½ grains (0.480 Gm.); tragacanth and althæa, of each 2 grains (0.128 Gm.); glycerin and water, of each 1 drop or a sufficient quantity.

Take of exsiccated ferrous sulphate, in fine powder, 150 grains; exsiccated sodium carbonate, in fine powder, 95 grains; acacia, in powder, 50 grains; tragacanth, in powder, 15 grains; syrup, 150 grains; glycerin, 10 grains; distilled water, 20 grains or a sufficient quantity. To the syrup, glycerin, and water, previously mixed, add the ferrous sulphate; mix and add quickly the sodium carbonate; after mixing, set aside until the reaction is complete; then add the acacia and tragacanth and mix thoroughly.—Br.

The formulas of the French and German pharmacopœias are similar to the above. The former directs the mass to be divided into pills weighing about 6 grains (0.40 Gm.), and the latter into pills weighing about 4 grains (0.25 Gm.). The P. G. orders for 9 parts of dried ferrous sulphate, 3 parts of sugar, 7 parts of potassium carbonate, 0.7 part of calcined magnesia, 1.3 parts of finely powdered althæa, and 4 parts of glycerin.

The official Blaud's pill is intended to contain about 1 grain (about 0.0667 Gm.) of ferrous carbonate, but unless protected by some suitable coating will undergo change after a short time, becoming oxidized and turning red. Hence the Pharmacopœia directs that the pills shall be made fresh when wanted.

H. A. B. Dunning (1900) suggested the following formula, which eliminates the tragacanth and althæa, as these have a tendency to make the pills tough and hard: Take of ferrous sulphate, in crystals, 15 Gm., potassium carbonate, 8.75 Gm., sugar, 1.25 Gm., powdered glycyrrhiza, 6.25 Gm. Rub the iron and sugar into fine powder, add the potassium carbonate, previously powdered, and mix with 40 minims of water. Triturate the mixture until dry and in powder, add the glycyrrhiza and sufficient glucose to make a smooth mass, which divide into 100 pills. Pills made by this formula retain their shape and green color for a long time, and while assuming a darker color on the outside, due to gradual drying, the interior remains fairly soft.

Uses.—Commonly known as Blaud's pill, it is largely used as a chalybeate tonic in chlorosis and other chlorotic anæmias. It approximately represents in pill form the Mistura Ferri Composita, or Griffith's Mixture. When prescribed the pills should be freshly prepared in a quantity to last only a few days. If kept on hand for a long time the ferrous carbonate changes to the ferric salt, and the pills become so hard that they do not readily disintegrate in the alimentary canal. The dose is from 1 to 6 pills three or four times a day.

PILULÆ FERRI IODIDI, *U. S.*—Pills of Ferrous Iodide.

Pilules d'iodure ferreuse, Fr. Cod.—*Pilules de Blancard*, Fr.; *Eisenjodürpillen*, G.

Preparation.—Reduced iron, 4 Gm.; iodine, 5 Gm.; glycyrrhiza, in No. 60 powder, 4 Gm.; sugar, in fine powder, 4 Gm.; extract of glycyrrhiza, in fine powder, 1 Gm.; acacia, in fine powder, 1 Gm.; water, balsam of tolu, ether, each a sufficient quantity to make 100 pills. To the reduced iron, contained in a porcelain capsule, add about 6 Cc. of water, and gradually add the iodine, constantly triturating, until the mixture ceases to have a reddish tint. Then add the remaining powders, previously mixed, and evaporate the excess of moisture on the water-bath, constantly stirring, until the mass has acquired a pilular consistence. Lastly, divide it into 100 pills. Dissolve 10 Gm. of balsam of tolu in 15 Cc. of ether; shake the pills with a sufficient quantity of this solution until they are uniformly coated, and put them on a plate to dry, occasionally stirring them until the drying is completed. Keep the pills in a well-stoppered bottle. —U. S.

Pills of ferrous iodide should be devoid of the smell of iodine. If a few pills be triturated with water, the filtrate should not assume more than a light blue tint on the addition of starch test-solution (absence of more than traces of free iodine).—U. S.

To make 12 pills use reduced iron, 7¼ grains (0.480 Gm.); iodine, 9¼ grains (0.60 Gm.); glycyrrhiza and sugar, of each 7½ grains (0.480 Gm.); extract of glycyrrhiza and acacia, of each 2 grains (0.128 Gm.).

An excess of iron is ordered in the formula, which is subsequently incorporated in the pill-mass. If the reduced iron were perfectly pure, 1.104 Gm. would be sufficient to combine with 5 Gm. of iodine, yielding 6.104 Gm. of ferrous iodide.

Owing to the heat produced by the reaction the iodine should be cautiously added in small quantities, to avoid loss by vaporization. Due precaution being exercised, the quantity of water directed in this part of the process may even be reduced a little, whereby subsequent evaporation may be avoided or materially lessened; if evaporation be necessary, the ferrous iodide is sufficiently protected by the excess of iron and by sugar, and without the presence of the other vegetable powders, which may be easily incorporated with the syrupy liquid. Owing to the gradual oxidation when exposed to the air, the pill-mass should not be kept on hand, but should be at once made into pills. To protect these against the influence of the air, they are directed to be coated with a thin layer of tolu balsam, or, according to the French Codex, with tolu balsam and mastic, used

in ethereal solution. The latter authority—whose process has, in the main, been adopted by the U. S. P., with several improvements—does not require an excess of iron to be incorporated with the pill-mass, but directs the freshly made pills to be rolled in finely powdered iron, and afterward to be coated as stated, thus affording an additional protection to the surface of the pill.

If properly made and preserved, these pills will keep for years without acquiring the smell of iodine or tarnishing a strip of bright metal suspended in the vial. Should oxidation take place to the extent of liberating iodine, distilled water on being triturated with a few of the pills will yield a filtrate which, on the addition of gelatinized starch, will acquire a more or less distinct green tint, resulting from the brown-yellow color of the extractive matter and the blue color of iodide of starch.

Each pill contains very nearly 1 grain (0.061 Gm.), U. S. P., or about ¾ grain (0.05 Gm.), Fr. Cod., of ferrous iodide.

Uses.—For action and uses, see SYRUPUS FERRI IODIDI. Each pill contains about 1 grain (0.06 Gm.) of ferrous iodide. Dose, 2 to 10 pills.

PILULA GALBANI COMPOSITA, *Br.*—Compound Pill of Galbanum.

Compound pill of asafetida, E.; *Pilules de galbanum composées*, Fr.; *Galbanumpillenmasse*, G.

Preparation.—Take of asafetida, galbanum, myrrh, of each 2 ounces; syrup of glucose, 1 ounce or a sufficient quantity. Heat all together on a water-bath, and stir the mass until it assumes a uniform consistence.—Br.

A similar pill was formerly official in France as *Pilules antihystériques*.

Uses.—This pill is rarely employed. It may be of value in functional nervous disorders as a sedative, in the dose of from 5 to 20 grains (0.30–1.30 Gm.).

PILULA HYDRARGYRI SUBCHLORIDI COMPOSITA, *Br.*—Compound Pill of Mercurous Chloride.

Pilulæ Antimonii Compositæ, U. S. 1890; *Pilulæ Calomelanos Compositæ.—Compound pills of antimony, Compound calomel pills, Plummer's pills*, E.; *Pilules altérantes composées, P. antidartreuses, P. de Plummer*, Fr.; *Zusammengesetzte Calomelpillen, Plummersche Pillen*, G.

Preparation.—Take of mercurous chloride, sulphurated antimony, of each 1 ounce; guaiacum resin, in powder, 2 ounces; castor oil, 180 grains; alcohol, 1 fluidrachm or a sufficient quantity. Mix to form a mass.—Br.

The U. S. P. 1890 directed sulphurated antimony, 4 Gm., mild mercurous chloride, 4 Gm., and guaiac, in fine powder, 8 Gm., to be made into a mass with castor oil, added drop by drop, the mass then to be divided into 100 pills.

Uses.—This pill has been used with some success in the treatment of chronic rheumatism and skin eruptions, especially those due to syphilis. The dose is from 3 to 10 grains (0.20–0.60 Gm.), or 1 to 3 pills.

PILULA IPECACUANHÆ CUM SCILLA, *Br.*—Pill of Ipecacuanha and Squill.

Pilules d'ipécacuanha et de scille, Fr.; *Brechwurzel-Meerzwiebelpillen*, G.

Preparation.—Take of compound powder of ipecacuanha, 3 ounces; squill, in powder, ammoniacum, in powder, each 1 ounce; treacle, a sufficiency. Mix the powders, and beat into a mass with the treacle.—Br.

Uses.—This pill exercises an expectorant effect in chronic bronchitis, especially when it occurs in the aged. Dose, 5 to 10 grains (0.30–0.60 Gm.).

PILULÆ JALAPÆ, *P. G.*—Pills of Jalap.

Pilules de jalap, Fr.; *Jalapenpillen*, G.

Preparation.—Resin of jalap, in fine powder, and soap, in fine powder, of each 1.5 parts; jalap, in fine powder, 1 part. Mix thoroughly and add alcohol sufficient to make a firm mass, which is to be divided into pills weighing 0.1 Gm. each.—P. G.

Uses.—The dose is from 1 to 5 pills. (See JALAPA.)

PILULÆ LAXATIVÆ COMPOSITÆ, *U. S.*—Compound Laxative Pills.

Pilulæ Aloini, Belladonnæ et Strychninæ Compositæ.—Compound Pills of aloin, belladonna, and strychnine, E.; *Pilules laxatives composées,* Fr.; *Zusammengesetzte Laxirpillen,* G.

Preparation.—Aloin, 1.3 Gm.; strychnine, 0.05 Gm.; extract of belladonna leaves, 0.8 Gm.; ipecac, in fine powder, 0.40 Gm.; glycyrrhiza, in fine powder, 4.6 Gm.; syrup, a sufficient quantity to make 100 pills. Triturate the aloin, strychnine, ipecac, and glycyrrhiza together thoroughly, so as to produce a uniform powder. Incorporate with this the extract of belladonna leaves and sufficient syrup to form a mass, and divide it into 100 pills.—U. S.

Action and Uses.—These pills, although favorably known to physicians for many years, appear for the first time in the Pharmacopœia. In order to insure perfect blending of the ingredients, the strychnine and ipecac should be mixed first, then the aloin added in divided portions, and finally, the glycyrrhiza, also in divided portions, triturating well after each addition. If powdered extract of belladonna leaves be used, this may be added to the mixture of strychnine and ipecac before the aloin. Each pill contains about $\frac{1}{3}$ grain (0.012 Gm.) of aloin; about $\frac{1}{13}$ grain (0.0005 Gm.) of strychnine; about $\frac{1}{8}$ grain (0.008 Gm.) of extract of belladonna leaves; about $\frac{1}{16}$ grain (0.004 Gm.) of ipecac; about $\frac{3}{4}$ grain (0.045 Gm.) of glycyrrhiza.

PILULÆ OPII, *U. S.*—Pills of Opium.

Pilules d'opium, Fr.; *Opiumpillen,* G.

Preparation.—Powdered opium, 6.50 Gm.; soap, in fine powder, 2 Gm.; to make 100 pills. Beat them together with water, so as to form a mass, and divide it into 100 pills.—U. S. For 12 pills use powdered opium, 12 grains (0.80 Gm.), and soap, 3 grains (0.20 Gm.).

Uses.—The dose is from 1 to 2 pills. (See Opium.)

PILULÆ PHOSPHORI, *U. S.*—Phosphorus Pills.

Pilula Phosphori—Phosphorus Pill, Br.—*Pilules au phosphore, Pilules phosphorées,* Fr.; *Phosphorpillen,* G.

Preparation.—Phosphorus, 0.06 Gm.; althæa, in No. 60 powder, 6 Gm.; acacia, in fine powder, 3 Gm; chloroform, glycerin, water, balsam of tolu, ether, each a sufficient quantity to make 100 pills. Dissolve the phosphorus, in a test-tube, in 5 Cc. of chloroform, with the aid of a very gentle heat, replacing from time to time any of the chloroform which may be lost by evaporation. Mix the althæa and acacia in a mortar, next add the solution of phosphorus, then immediately afterward a sufficient quantity (about 4 Cc.) of a mixture of 2 volumes of glycerin and 1 volume of water, and quickly form a mass, to be divided into 100 pills. Dissolve 10 Gm. of balsam of Tolu in 15 Cc. of ether, shake the pills with a sufficient quantity of this solution until they are uniformly coated, and put them on a plate to dry, occasionally rolling them about until the drying is completed. Keep the pills in a well-stoppered bottle.—U. S.

Take of phosphorus, 10 grains; white beeswax, melted, and lard, melted, of each 125 grains; kaolin, 115 grains; carbon disulphide, 33 minims or a sufficient quantity. Place the melted wax and lard in a slightly warmed mortar, and stir until the mixture has the consistence of cream. Dissolve the phosphorus in the carbon disulphide and carefully mix the solution with the melted fats, after which add the kaolin and mix well together. Keep the mixture immersed in cold water in a bottle from which the light is excluded. When dispensed, every 3 grains of the mixture is to be incorporated with 1 grain of acacia, in powder, and the resulting pill is to be varnished.—Br.

Phosphorus requires to be kept under water and to be weighed out under a liquid in which it is not oxidized, either water or chloroform. By melting a small quantity of phosphorus under warm water contained in a vial, and then agitating it well until the phosphorus has solidified, this is obtained in small granules, which are conveniently handled, and after having been rapidly dried with filtering-paper, are at once dropped into the previously tared liquid until the desired quantity has been obtained.

Tolu as a vehicle for phosphorus in pills was proposed by A. C. Abraham (1874), who observed that it will retain 4 per cent. of the latter if combined with it in the melted condition. A. W. Gerrard (1873) had previously made a similar observation with regard to resin, and this preparation became known at the time as *phosphoretted*

resin; it is prepared by melting the resin in a wide-mouthed vial, adding the requisite quantity of phosphorus, and, when it has melted, agitating the stoppered vial until the phosphorus is dissolved. Like resin, it may be powdered, and, like the pill-mass of the British Pharmacopœia, it should be kept under water to prevent oxidation.

Since phosphorus is rapidly oxidized, particularly in a state of fine division, pills of phosphorus should be coated as soon after they have been made as possible; as in the case of pills of ferrous iodide, the alcoholic solution of mastic and balsam of Tolu is preferable to the official ethereal solution.

Uses.—Each pill contains $\frac{1}{100}$ grain (0.0006 Gm.) of phosphorus. The dose is from 1 to 2 pills. (See PHOSPHORUS.)

PILULA PLUMBI CUM OPIO, *Br.*—Pill of Lead and Opium.

Pilules d'acetate de plomb et d'opium, Fr.; *Bleiacetat-Opiumpillenmasse,* G.

Preparation.—Take of lead acetate, in fine powder, 36 grains; opium, in powder, 6 grains; syrup of glucose, 4 grains or a sufficient quantity. Mix to form a mass.—Br.

Uses.—It is unnecessary to have these drugs combined in a fixed formula. The proportions to be employed had better be left to the discretion of the prescriber in each case. The combination is of value in dysentery and diarrhœa, particularly of a chronic character. It should always be preceded by a saline or castor oil purge if used in acute diarrhœa when there is much mucus in the stools. Each 3 grains contain $2\frac{1}{4}$ grains (0.115 Gm.) of lead acetate and $\frac{3}{8}$ grain (0.024 Gm.) of powdered opium. The dose is from 3 to 5 grains (0.20–0.30 Gm.).

PILULÆ PODOPHYLLI, BELLADONNÆ ET CAPSICI, *U. S.*—Pills of Podophyllum, Belladonna, and Capsicum.

Pilules de podophyllum, de belladonne et de poivre de Guinée, Fr.; *Podophyllin-, Belladonna und Spanisch-Pfefferpillen,* G.

Preparation.—Resin of podophyllum, 1.6 Gm.; extract of belladonna leaves, 0.8 Gm.; capsicum, 3.2 Gm.; sugar of milk, 6.5 Gm.; acacia, in fine powder, 1.6 Gm.; syrup, glycerin, of each a sufficient quantity to make 100 pills. Triturate the resin of podophyllum, capsicum, sugar of milk, and acacia together to produce a uniform powder. Incorporate with this the extract of belladonna leaves and sufficient syrup and glycerin (equal parts) to form a mass, and divide it into 100 pills.—U. S.

For 12 pills use resin of podoyhyllum, 3 grains (0.195 Gm.); extract of belladonna leaves, $1\frac{1}{2}$ grains (0.098 Gm.); capsicum, 6 grains (0.390 Gm.); acacia, 3 grains (0.195 Gm.), and sugar of milk, 12 grains (0.78 Gm.).

This pill is one of the new additions to the Pharmacopœia, although the formula has been known to the medical profession for many years. It is sometimes designated as Squibb's podophyllum pill, because the combination was first suggested by the late Dr. E. R. Squibb.

Uses.—This is a useful pill in cases of constipation with hepatic torpor and gastro-intestinal atony. Dose, 1 to 3 pills.

PILULA QUININÆ SULPHATIS, *Br.*—Pill of Quinine Sulphate.

Pilule de quinine sulfate, Fr.; *Chininpillenmasse,* G.

Preparation.—Quinine sulphate, 30 grains; tartaric acid, 1 grain; tragacanth, in powder, 1 grain; glycerin, 4 grains. Triturate the quinine sulphate with the acid; add to the tragacanth and glycerin previously mixed, and form a mass.—Br.

Uses.—The dose is from 2 to 30 grains (0.10–2 Gm.). (See QUININÆ SULPHAS.)

PILULÆ RHEI COMPOSITÆ, *U. S., Br.*—Compound Pills of Rhubarb.

Compound rhubarb pill, E.; *Pilules de rhubarbe composées,* Fr.; *Rhabarber und Aloepillen,* G.

Preparation.—Rhubarb, in No. 60 powder, 13 Gm.; purified aloes, in fine powder, 10 Gm.; myrrh, in fine powder, 6 Gm.; oil of peppermint, 0.5 Cc.; to make 100 pills. Beat them together with water so as to form a mass, and divide it into 100 pills.—U. S.

For 12 pills use rhubarb, 24 grains (1.56 Gm.); aloes, 18 grains (1.20 Gm.); myrrh, 12 grains (0.78 Gm.); oil of peppermint, about 2 drops.

Take of rhubarb-root, in powder, 3 ounces; socotrine aloes, in powder, 2¼ ounces; myrrh, in powder, hard soap, in powder, each 1½ ounces; oil of peppermint, 1½ fluidrachms; syrup of glucose, 2¾ ounces or a sufficient quantity. Mix the powders with the oil, then add the syrup, and beat the whole into a uniform mass.—Br.

Uses.—These pills are used in chronic constipation with flatulence. Dose, 1 to 4 pills.

PILULA SAPONIS COMPOSITA, *Br.*—Compound Pill of Soap.

Pilules de savon composées, Fr.; *Seifenpillenmasse*, G.

Preparation.—Take of opium, in powder, ½ ounce; hard soap, in powder, 1½ ounces; syrup of glucose, ½ ounce. Mix to form a mass.—Br.

Uses.—Each 5 grains (0.30 Gm.) of this mass contains 1 grain (0.05 Gm.) of opium. It presents the advantage of affording a disguise under which to prescribe opium. The dose is from 3 to 10 grains (0.20–0.60 Gm.).

PILULA SCAMMONII COMPOSITA, *Br.*—Compound Scammony Pill.

Pilules de scammonée composées, Fr.; *Scammoniumpillenmasse*, G.

Preparation.—Take of scammony resin, jalap resin, curd soap, in powder, each 1 ounce; tincture of ginger, 3 fluidounces. Add the tinctures to the soap and resins, and dissolve with the aid of a gentle heat; evaporate on a water-bath until the mass has acquired a suitable consistence for forming pills.—Br.

The process adopted furnishes a very good pill-mass, in which the resins are uniformly divided through the agency of the soap, which also keeps them in suspension when the mass is macerated with water.

Uses.—This mass is a drastic purge, given in the dose of from 3 to 5 grains (0.20–0.30 Gm.).

PILULA SCILLÆ COMPOSITA, *Br.*—Compound Squill Pill.

Pilules de scille composées, Fr.; *Meerzwiebelpillenmasse*, G.

Preparation.—Take of squill, in powder, 1¼ ounces; ginger, in powder, ammoniac, in powder, hard soap, in powder, each 1 ounce; syrup of glucose, 1 ounce or a sufficiency. Mix to form a mass.—Br.

Uses.—In the dose of from 5 to 10 grains (0.30–0.60 Gm.) this pill is a useful stimulating expectorant in chronic bronchitis. (See SCILLA.)

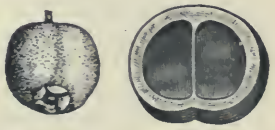
PIMENTA, *U. S., Br.*—Pimenta; Allspice.

Semen amomi, Piper jamaicense.—Pimento, E.; *Nelkenpfeffer, Englisches Gewürz, Neugewürz*, G.; *Pimenta de la Jamaique, Toute-épice*, Fr.; *Pimienta gorda, Malaguecta*, Sp.; *Pimenta de Jamaica*, Port.

The dried, nearly ripe fruit of *Pimenta Pimenta* (L.) Lyons (*Myrtus P.* L.; *Eugenia P.* DC.; *Pimentus P.* Griseb.; *Pimenta officinalis* Lindl.; *P. vulgaris* W. et A.—Fam. *Myrtaceæ*).

Allspice is official in most pharmacopœias, though only the Portuguese employs the correct specific name, and this does so in connection with the incorrect generic name *Eugenia*. The Allspice tree is a native of the West Indies and other parts of tropical America, being especially abundant in Jamaica, where it constitutes the principal forest-tree over large areas. As it grows in Mexico and other parts, it varies considerably, so that questions arise as to whether such forms are not distinct species. In the case of the Mexican form, which has been classed as a distinct species, *P. Tobasco* (W.), *Myrtus T.* W., this question becomes of practical importance, since that tree yields a commercial allspice, "Pimienta de Tobasco," which has been variously classed as a variety and as an adulterant of Allspice. The Allspice tree is cultivated in various tropical countries. In Jamaica, such cultivation consists usually, or has

FIG. 318.



Allspice (× 2): transverse section (Nat.).

done so, in merely clearing out other trees from the forests and allowing the Allspice trees to occupy the ground. The tree begins to fruit when three years old and is in full bearing after four years more. If the fruit is allowed to ripen, it loses almost the whole of its aromatic properties, becoming fleshy, sweet, and of a purple-black color. It is, therefore, collected while yet green, and dried, either by exposure to the sun or in ovens ("Kiln-dried Allspice"). The former method produces the best article, but is tedious and somewhat hazardous, requiring about 12 days, during which the fruit must be carefully guarded against moisture, being housed at night and during rainy and damp weather. The fruit is essentially a 2-celled and 2-seeded drupe.

Description.—About 6 Mm. ($\frac{1}{4}$ In.) in diameter, depressed-globose, slightly flattened, each of the flattened sides bearing an obscure groove, the saucer-shaped and 4-lobed calyx limb and the style, or their remnants, at the summit; dark brown, strongly granular; brittle, 2-celled, and 2-seeded; strongly and peculiarly aromatic in odor and taste.

Allspice is little subject to adulteration in the entire condition. Years ago, when it was scarce and high, the fruit of the common spice bush, *Benzoin Benzoin* (L.) Coulter, was used for this purpose. The ground article, for household consumption as a spice, is, of course, subject to the same low and gross forms of adulteration as other similar substances.

Constituents.—The important constituent of Allspice is its 2 to 4 per cent. of volatile oil (see OLEUM PIMENTÆ), mostly in the pericarp, together with resin, tannin, fat (chiefly in the seed), sugar, mucilage, etc. The ash should amount to little more than 4 per cent.

Pharmaceutical Preparation.—PIMENTO WATER, Br.

Action and Uses.—Pimenta, like other drugs containing aromatic volatile oils, is used as a carminative, a flavoring agent, a stimulant to digestion, and to prevent the griping of purgative medicines. It is one of the ingredients of spice plaster. The dose of the official oil, which is generally employed, is from 2 to 5 minims (0.10–0.30 Cc.), and that of the powdered drug 10 to 40 grains (0.60–2.60 Gm.).

Other Species.—The genus *Pimenta* is credited with 5 species, though the number is somewhat uncertain. They are all more or less aromatic.

In the East Indies the fruits of a related plant, *Eugenia acris* W. et A., are similarly employed. They are more pungent than Allspice, having more of the flavor of Jamaica Bay Leaves and fruit.

PINUS STROBUS.—White Pine.

The inner bark of *Pinus Strobus* L. (Fam. *Pinaceæ*).

This species, the *Northern, Weymouth,* or *Deal Pine,* is a very large and handsome tree of eastern and central North America, formerly so abundant as to supply one of our cheapest, as well as one of our best, soft-wood timbers, now becoming scarce.

Description.—In flat pieces of irregular size and from 1 to 3 Mm. ($\frac{1}{25}$ to $\frac{1}{8}$ In.) thick, the outer surface varying from pale brown to a rather deep yellow brown, when fresh having a pale-pinkish tinge, occasionally bearing small patches of the gray-brown corky layer, fuzzy with partly detached fine bast-fibers, often exhibiting scattered small pits; inner surface either lighter or darker than the outer, nearly smooth, finely striate; fracture very tough-fibrous; transverse section pale yellow in the outer, whitish in the inner layer; odor faintly terebinthinate; taste mucilaginous, sweetish, bitterish, and astringent.

Constituents. The constituents of white pine bark are not well known. Bastin and Trimble found about 9 per cent. of tannin in the stem-bark, about 11 per cent. in the root-bark. The stem-bark yielded to absolute alcohol only 30 per cent. of its weight, and this yielded a little less than a third of its weight to water. The bark also contains gum, resin, and a little of the peculiar body coniferin ($C_{16}H_{22}O_8.H_2O$), which occurs in fine lustrous needles, melting at 185° C. (365 F.), soluble in hot water, and yielding vanillin upon oxidation. It exists in greater quantity in the cambium-layer left attached to the wood, and appears to be widely distributed in the cambium of different genera and species of this family.

Pharmaceutical Preparation.—COMPOUND SYRUP OF WHITE PINE, N. F.

Action and Uses.—Pinus strobus is used as an expectorant, but has little power. It is one of the ingredients of the compound syrup of white pine (N. F.), which is given in the dose of from 1 to 4 drachms (4–16 Cc.).

Pinaceæ.—CONIFERÆ (*The Pine Family*).—The *Cone-bearers*, nearly all of them evergreens, comprise one of the most interesting, as well as one of the most important, families of plants. The principal family of Gymnosperms, they constitute the great connecting link between the flowerless and the flowering plants, and are thus of the greatest botanical interest. The living members of the family are doubtless far fewer, and their natural importance certainly far less, than those which are extinct. The group is, in fact, in the process of suffering extinction, and the careless procedures of mankind concerning them are greatly expediting this *finale*. In economic importance, the timber-product of the family stands first. It contributes most, and the best, of the soft-wood timbers, and there are no others in existence which can compare with them. Paper-pulp is produced in vast quantities from the spruces. Tanning materials, especially hemlock bark, are of great importance. The corky portion of the bark of the Oregon Spruce (*Pseudotsuga Douglasii* Carr.) has been proposed as a substitute for ordinary corks, but is very inferior. Some of the seeds supply highly important foods, especially those of *Araucaria imbricata* Pavon, of Chile; *Pinus Cembra* L., the *Siberian stone-pine* or *cedar* of Europe and northern Asia, yielding the *Zibel Pine-nuts*; *P. pinea* L., of southern Europe, yielding the Italian *Pignone* or *Pinnochi*; *P. edulis* Englm., of the southwestern United States and southward, yielding the *Mexican Pinyon*; *P. cembroides* Zucc. yielding the *Stone-seed pinyon*; *P. Sabiniana* Dougl., the famous *Digger* or *Nut pine*, etc. This family supplies nearly all our turpentine, and by far the largest part of our tar and pitch, apart from that obtained from coal.

From a medicinal standpoint, the general nature of the constituents and products and their properties are elsewhere pretty fully discussed, in connection with JUNIPERUS, TEREBINTHINA, THUJA, PIX BURGUNDICA, PIX LIQUIDA, OLEUM CADINUM, SABINA, RESINA, SANDARACA, etc. Most important of the constituents are the volatile oils, of which oil of turpentine may be regarded as the type. Besides those oils which occur as exudations, a somewhat different class are distilled from the fresh twigs of various species. These will be referred to under OLEA VOLATILIA. Next in importance to the oils is the tannin, which often exists in considerable amount, and which appears to vary inversely in amount, in different seasons and under different conditions, with that of the volatile oil, which thus appears to be a product of the destruction of the former. Glucosides are numerous and widely distributed, though for the most part devoid of important special properties.

Alkaloids are rare in this family, but at least one of them is very poisonous.

The following secondary drugs of the family are worthy of brief notice:

Laricis cortex or *Larch bark* (*Lärchenrinde*, G.; *Écorce de mélèze*, Fr.; *Corteza de alerce*, Sp.) is the bark, deprived of its rough outer layer, of *Larix Larix* (L.) Karsten (*Pinus L.*—L.; *Larix Europœa* DC.; *L. decidua* Mill.; *Abies Larix* Lam.). The European larch is a good-sized tree, occurring in somewhat elevated forests in southern and central Europe, and is well known as a decorative tree in the United States. It is notable for its yield of *Venice turpentine*, and from its sugary exudation known as *Briançon manna*. The bark of the trunk and larger branches is collected in the spring, after the outer corky layer has been shaved off, and dried. The older bark then occurs in flattened or slightly curved pieces, the outer surface varying from a light to a dark red, the inner surface pinkish red. The younger bark is in more or less quilled pieces, is pinkish white on the outer and yellowish white on the inner surface. The fracture is short, but somewhat fibrous, and, excepting the inner layer, is of a carmine red. The transverse section displays rather indistinct medullary rays and some resin-ducts. The odor is somewhat balsamic and terebinthinate, and the taste astringent and somewhat bitter. Larch bark contains a little volatile oil, but principally tannin and resin, together with *laricinic acid* ($C_{10}H_{10}O_5$), the latter mostly in the younger bark. This is volatile and forms long, colorless crystals like those of benzoic acid, subliming at 93° C. (199.4° F.), melting at 150° C. (302° F.), sparingly soluble in ether and freely so in alcohol and hot water, and have a camphoraceous odor and a bitterish and astringent taste. Baryta solution causes a bulky precipitate; nitric acid oxidizes it to oxalic acid; baric salts produce a purple color, and on boiling it with silver salts the metal is separated. It is allied to pyrogallol and pyrocatechin. In the form of an extract and tincture made from the inner bark, Larix is employed in chronic bronchitis with profuse expectoration, in chronic inflammation of the urinary passages, and in purpura hæmorrhagica, hemoptysis, and other hemorrhagic affections. The dose of the tincture is from 30 to 60 minims (2–4 Cc.); of the extract, from 3 to 5 grains (0.2–0.30 Gm.).

Hemlock bark is the bark of *Tsuga Canadensis* (L.) Carr. (*Pinus C.*—L.; *Abies C.*—Mx.), the *Hemlock*, *Hemlock* or *Weeping spruce*, or *Spruce pine*, native of eastern North America, and a large tree. This bark is one of the important tanning products of America. It is inferior to oak bark. For tanning purposes, the entire bark is usually marketed, but in pharmacy the rough outer layer is usually removed, as in case of larch bark. In its general appearance it resembles the latter, but the red of the outer surface is more strongly tinged with yellow or brown, and the inner surface is yellowish white. The fracture is rather more fibrous, and the transverse section is mottled, brownish, and whitish. The odor is slight, the taste strongly astringent. Ordinarily the bark contains very little resin or volatile oil, but

is very rich in tannin, for which it is used as an astringent. Its aqueous extract is an important article of commerce, mostly for tanning, but also for medicinal purposes.

Under natural processes of decay, or as a result of injury to this tree, an oleoresin is freely secreted which is the basis of the PIX CANADENSIS, elsewhere considered. From the twigs of this tree is distilled *Oil of Spruce* or *Hemlock*. Westward this species is replaced by *T. Mertensiana* (Boug.) Carr., the *Western hemlock* or *Patton's spruce*, which is similar in habit, constituents, and uses.

False Balm of Gilead Buds are obtained from *Abies balsamea* (L.) Mill. (*Pinus b.* L.), the Balsam Fir, etc., of Canada and eastern United States. From the twigs of the related species *A. Abies* (L.) Rusby (*Pinus A.*—L.; *P. excelsa* Lam.; *P. Picea* Du Roi) Tanret has separated the glucoside *picein* ($C_{14}H_{18}O_7.H_2O$), which occurs in bitter, silky needles, soluble in water and alcohol, less in ether, and yielding *piceol* on decomposition. It is very likely that the same glucoside occurs in False Balm of Gilead Buds, which are highly aromatic, resinous, bitter, and somewhat astringent.

Cedar apples are the insect galls occurring in the twigs of *Juniperus Virginiana* L. Besides their astringent properties, they are very bitter and are sometimes used in domestic practice as an anthelmintic.

Taxus, or *Yew*, is the leaves of various species of *Taxus*, especially of *T. baccata* L., the *European yew*, *Snottle berry*, *Shin-wood*, or *Globe berry* (*Eibe*, G.; *If commun*, Fr.; *Tejo*, Sp.) of Asia and Europe and extending southward into northern Africa.

Similar properties doubtless pertain to the east American species *T. minor* (Mx.) Britton (*T. baccata minor* Mx.; *T. Canadensis* W.), and to the West American species, the *Oregon yew*, *T. brevifolia* Nutt. The European species, though usually a shrub, sometimes becomes a small tree. That of eastern North America is a stout, prostrate shrub, the branches rooting rather freely. The nearly sessile leaves are crowded in 2 ranks and are about 2.5 Cm. (1 In.) long, linear, pointed, entire, flat, slightly curved, deep green and shining above, pale underneath. It produces globose-ovoid, scarlet-red, wax-like fruits, the fleshy part cup-shaped and open at the top, containing a single large blackish-brown seed, and subtended by several small scales. The leaves are aromatic, terebinthinate, and, like the seed, disagreeably bitter, afterward acrid. The pulp of the fruit is sweetish and not unpleasant, hence has been responsible for various poisoning accidents. Both the leaves and the fruit have been employed to some extent in medicine, but are now scarcely ever used. Besides volatile oil and tannin, the leaves, as well as the seeds and bark, contain the alkaloid *taxine*, which is the poisonous constituent. It occurs in crystals, which melt at 80° C. (176° F.), are soluble in alcohol, ether, and chloroform, slightly in water, insoluble in petroleum-ether, colored purplish red by sulphuric acid, but dissolving without color in other acids. Other nitrogenous constituents have been reported, but their nature is very doubtful.

PIPER, *U. S.*—Black Pepper.

Piper nigrum, Br.; *Poivre noir*, Fr. Cod.; *Schwarzer Pfeffer*, G.; *Pimienta negra*, Sp.; *Pimenta negra*, Port.

The dried unripe fruit of *Piper nigrum* L. (*P. trioicum* Roxb.—Fam. *Piperaceæ*).

Black pepper is official in a number of pharmacopœias, including the British, but not the German.

Origin.—The pepper plant is a woody, evergreen, dicœcious climber, obtaining support from living trees by means of great numbers of small roots. It has been cultivated in the East Indies from prehistoric times, and its nativity was unknown until its identity with a wild plant of India, previously known as a distinct species and called *P. trioicum*, was recognized. Propagation is effected by means of cutting or layering, and the young plants are set out at the roots of trees, specially planted for the purpose or left standing when the land is cleared. This tree is almost invariably the Betel, thus affording two crops from the same land. Fruiting commences in from 3 to 5 years and continues for about 20 years. The habit of leaf, flower, and fruit are indicated in the accompanying illustration. The fruit is at first green, then red, and finally yellowish. If left until it becomes ripe, not only is loss occasioned through its being eaten by birds or falling to the ground, but its quality is greatly impaired. It is therefore gathered when full grown and changing to a red color. It is either dried at once or after a slight boiling.

Several grades of pepper are recognized, in accordance with the relative weight of the grains. That of Penang and Malabar is denominated "heavy," that of India "light," while that of intermediate quality is denominated "half heavy." That of the Straits Settlement, which is at the same time the principal product, is most highly esteemed.

Description.—About 4 Mm. ($\frac{1}{6}$ In.) in diameter, nearly globular, blackish, very strongly reticulate-wrinkled, bearing a low style-base at the summit and consisting of a thin fleshy pericarp and a crustaceous, whitish putamen containing a more or less undeveloped seed; odor characteristic, strong; taste strongly aromatic and pungent.

The outer zone (epicarp) and the middle zone (sarcocarp) are dark colored. Except for the innermost or vascular layer of the sarcocarp, these zones are practically devoid of starch. The vascular layer of the sarcocarp contains some starch. The inner zone of the pericarp (putamen or stone) is light colored. Its outermost layer consists essentially of peculiar stone-cells. The remainder of it is mostly starch-bearing tissue. The seed is also light colored, and contains a great quantity of starch.

The powder is characterized by the great abundance of stone-cells, in masses, and extremely small (0.0005 to 0.005 Mm.), angular, simple and compound starch-grains with nearly central hilum, as well as by the specific constituents of the drug. The stone-cells are large, angular, and highly irregular in form. The parenchymatic tissue varies from yellowish to brown.

FIG. 319.

Piper nigrum L.

Constituents.—The most important constituent of pepper, medicinally, is *piperine* or *piperina*, which, with its derivatives, *piperidine* and *piperic acid*, is separately considered under that title. It exists in nearly all parts of the fruit, though less in the outer zone, and is chiefly (perhaps wholly) responsible for the pungency. The amount of piperine ranges usually from 4.5 to 5.5 per cent., though occasionally as much as 8 per cent. has been reported. A variable amount of pungent resin is present, which is soluble in alcohol, ether, and alkalies. The nature of this resin is not very well known. It is at least possible that its pungency is due to the specific constituents piperine and piperidine carried in it. Black Pepper contains about 2 per cent. of a volatile oil (*Oleum Piperis, Pfefferoel, Essence de poivre*), which imparts the odor but not the pungency. This oil ranges from nearly colorless to yellow or greenish, has a specific gravity of from 0.87 to 0.90, and is soluble in 15 parts of alcohol. It contains dipentene, phellandrene, and a peculiar terpene. Piperine and piperic acid exist free in small quantity. Tannin is wanting. The starch amounts to from 30 to 40 per cent. The ash ranges from 4.5 to 6.5 per cent., and its ordinary legal limit is 6.5 per cent. The older and riper the Pepper. or the greater the amount of outer portion present in it, the larger is the ash percentage.

Adulteration.—Adulteration of Black Pepper in the entire condition is little practised, except by the inclusion of the stalks, chaff, and siftings (see *Allied Products*).

Ground Black Pepper is very heavily and commonly adulterated. It should consist of the entire fruit, ground without change, but the practice largely prevails of grinding with it the outer layers (Pepper shells) removed from other lots for the making of White Pepper. These pepper shells are removed in different layers, preserved separately ("first grinding," "second grinding," etc.), the outermost being successively poorer. By the lighter process the inner or vascular layer of the sarcocarp remains attached to the putamen. Such shells, therefore, contain very little or no starch, but yield a much higher percentage of ash, up to 12 or 13 per cent. or more. From the above, it follows that pepper to which pepper shells have been added, will be darker in color, richer in ash, poorer in starch, and less active. To obviate most of these changes, foreign starch or starchy substances are then often added. This foreign starch can be at once recognized by microscopical examination, owing to the striking peculiarities of Pepper starch. The starches most commonly employed are those of the yam or sweet potato, though rice and damaged flour are not uncommonly used. All these starches are described and figured in the article on AMYLUM. The addition of these foreign starches to pepper shells in sufficient quantity to equal the normal amount can usually be detected by a change in the general appearance of the mass. They impart a lighter color to it than the presence of the same amount of the natural starch and at the same time a dull and

fluffy aspect to its surface. Sand is a very common addition, at once detected upon incineration, and especially upon an examination of the character of the ash. Sand can also be detected by the microscope, though many of the stone-cell masses somewhat resemble yellowish sand particles upon careless examination. Olive-stones are occasionally ground up with pepper. They add a large amount of vascular tissue to the powder. Their stone-cells are mostly lanceolate or lance-ovate and are distinguished by a very slender, straight central lumen, with short straight branches alternating at right angles and at regular distances upon its two sides. There is no coloring-matter within the cells, whereas such coloring-matter exists in the stone-cells of pepper. Aniline acetate gives to the coloring-matter of olive-stones a yellow-brown color, thalline an orange, and naphthylamine a yellowish orange. Numerous other substances are similarly used, such as the shells of walnuts, almonds, and cocoanuts. The last named are largely used, either raw or roasted, for this purpose.

Pharmaceutical Preparations.—Confection of Pepper, Br.; Oleoresin of Pepper, U. S. P.

Action and Uses.—Pepper is a powerful local and general stimulant. It has a burning taste, due to the resin, and in large quantity may cause distinct irritation of the mouth and throat. Internally it produces a sensation of warmth in the abdomen, increases the flow of gastric and intestinal secretions, and reduces flatulence. It may be used in all cases of atony of the mucous membrane of the genito-urinary system, but is contraindicated if any acute inflammation exists, as in acute gonorrhœa. Locally it causes distinct pain and redness of the skin. From the most remote times it has been used as a condiment. At different periods of the past pepper and its principle, piperin, were esteemed in the treatment of intermittent fevers, but in the light of our present knowledge of the cause of this disease, the use of the drug as a cure has been abandoned. However, it is employed in malaria, along with cinchona or its alkaloids, to increase their absorption and efficacy. In the form of a poultice or plaster it relieves headache, colic, muscular rheumatism, and other local pains. The dose of pepper is from 5 to 20 grains (0.30–1.30 Gm.), best given in powder on food or in capsule.

Allied Products.—Pepper-stalks or stems consist of the rachis or stem to which the pepper fruits grow attached. Their presence in the powder is indicated by a great abundance of fibro-vascular tissue. Widmayer has pointed out that the epidermis of these stems exhibits little conical depressions, in each of which there is contained a black, top-shaped mass, excreted through a pore at the point of the cavity. Pepper-chaff consists of light membranaceous matter, largely leaf-fragments, separated by winnowing. Pepper siftings or screenings consist in part of stalks, with various foreign substances, but principally of small, hollow, undeveloped light fruits which are much sunken and dented instead of being merely wrinkled. They are often called, commercially, "pin-heads." Their presence in the powder produces results very similar to those of pepper-shells.

Piper album or *White pepper* is produced in several ways. The Singapore variety consists of young fruit dried without change except that it is often bleached by the use of chlorine or in other ways. These fruits have about half the diameter of black pepper, bear a slight protuberance at the top, are grayish or slightly greenish white, little wrinkled, and slightly shining. Native or "commercial" White Pepper is made by allowing the fruit to get as nearly ripe as possible before collecting, and then, by abrasion before drying, removing the sarcocarp down to the vascular layer, the fruit usually being slightly boiled first to facilitate the process. The third or "machine" form of White Pepper has already been referred to as being made by grinding off the sarcocarp from commercial Black Pepper. It is readily distinguished from the second variety by the irregularly abraded or broken appearance of its outer surface, instead of the roughish-veiny appearance of the native product. The character of ground White Pepper can be readily inferred from what has preceded. Its appearance can be stated as being in all respects the direct opposite of that of ground pepper-shells. The composition of White Pepper will naturally vary according to the method of its production. Native White Pepper, being deprived of its outer portions only, will be very rich in both starch and piperine, with a diminished ash-percentage, ordinarily about 4.5 per cent. The third variety named will be very similar, provided only the outer layers have been ground away. If, however, the process has been carried to the point of grinding down to the putamen, the percentage of piperine will be somewhat less than in the Black Pepper, with an increase in that of the starch. The conflicting statements in works of reference regarding the percentage of piperine in White Pepper doubtless result from the examination of the different varieties here referred to. Vascular tissue will be very slight in amount in the machine variety.

Long Pepper, Piper Longum, or *Elephant Pepper, Piovre long* (Fr.), *Pimienta larga* (Sp.). is the immature and partly grown fruit, still upon the rachis, of *Chavica officinarum* Miq.

(*Piper o.* DC.; *P. Chava* Hunter) or of *C. longum* (L.) Miq. (*Piper l.* L.; *C. Roxburghii* Miq.). Both are produced by shrubs, the first named being native of Java and its product known as Java or Dutch Long Pepper, the second of India and known as Indian or Bengal Long Pepper. Long Pepper is 2.5 to 3.8 Cm. (1 to 1½ In.) long and 3 to 6 Mm. (⅛ to ¼ In.) thick, cylindraceous, very slightly tapering, blunt, borne on a very short and thick stem, and consisting of densely spirally arranged and partly coalescent fruits having the general, though only partly developed, structure of Black Pepper. Both are blackish, the Bengal of a reddish black, the Java usually gray powdery on the surface. The Java averages from a third to a half longer than the Indian and is generally regarded as superior. The odor and taste, as well as the constituents, of Long Pepper are very similar to those of Black Pepper.

Schinus molle L.—In Peru and other parts of tropical America, the fruits of this plant (Fam. *Anacardiaceæ*), the *Pepper tree, Peruvian mastiche tree* or *Arbol del Peru*, have a slight domestic use as a pepper-substitute under the name of *Chilian* or *Peruvian Pepper*. The tree is quite beautiful, somewhat resembling an ash tree, but with very slender, partly drooping branches, and is planted for shade and ornament as far north as California. It bears large drooping panicles of spotted crimson fruits, about as large as pepper, which are somewhat pungent. All parts of the plant are used medicinally, the bark as an astringent, and the leaves as an aromatic, as is the gum-resinous exudation, which has been found to contain 60 per cent. of resin and a little volatile oil.

The genus *Piper* contains nearly 400 species of tropical plants, characterized generally by aromatic or pungent properties, and a large number are in use on this account. The fruit of *P. Guineense* Sch. et Th., used like pepper under the name *Guinea* or *Kissine pepper*, contains 11.5 per cent. of essential oil and 5 per cent. of piperine or about double the amount contained in ordinary black pepper. The root of *P. reticulatum* L. is pungent and is used in Brazil under the name Jaborandi, as are also *P. unguiculatum* R. et P. and others. The fruit of *P. Novæ-Hollandæ* Miq. is very pungent and is used under the name *Australian pepper*. The rhizomes of *P. peltatum* L. and *P. umbellatum* L. are used in the West Indies as diuretics, under the names *Caapeba* or *Periparabo*, or, in English, *Lizard's-tail* or *Asses'-foot*. In the West Indies, the leaves of *P. ovatum* Vahl., under the name *Pot*, are fed to hunting-dogs to improve the scent. It contains the peculiar alkaloidal but non-basic body *Piperovatine* ($C_{16}H_{21}NO_2$), insoluble in water or ether, but soluble in alcohol, chloroform, or acetone. It is allied to piperine. The leaves and fruits of *P. anisatum* Kunth, of tropical America, have an anise-like odor and taste. In the Andes the fruits of *P. crocatum* R. et P. (*Artanthe c.*—Miq.) are used as a pepper-substitute and for dyeing. In all, nearly 100 species of the genus have been recorded as in medicinal use.

Piperaceæ or *Pepper Family.*—The genus Piper comprises about half of the species of this family. METHYSTICUM, CUBEBA, and MATICO are important drugs pertaining to it, and are considered under these titles.

Betel leaves are the product of *Chavica Betle* (L.) Miq (*Piper B.*—L.), a shrubby twiner, native of the East Indies and considerably cultivated for its leaves. The leaves are broadly ovate, obliquely cordate, acuminate, 5- to 7-nerved, coriaceous, smooth, and above shining, and of a burning, aromatic, and bitter taste. They are enormously used by the Malays as a masticatory, being usually chewed with scrapings of Areca, often mixed with slaked lime. The leaves of *C. Siriboa* (L.) Miq. (*Piper S.*—L.) are very similar, though less distinctly cordate, and are similarly employed. A number of species of the genus *Peperomia* are also employed as aromatics.

Saururaceæ (the *Lizard's-tail Family*).—This small family, of 3 genera and 4 species, was long regarded as a part of the preceding. All are medicinally employed. The most important is the *Yerba Mansa*, the rhizome and root of *Houttuynia Californica* B. et H. (*Anemiopsis C.*—H. et A.; *A. Berlandieri C.* DC.), a perennial herb of the southwestern United States and Mexico. It is scarcely an article of general commerce, but is perhaps the favorite antispasmodic of the Mexicans. The herbage is also somewhat employed. The constituents have not been studied. *Saururus cernuus* L. (*Black Sarsaparilla*), of the eastern United States, and *S. lucidus* Don., of South America, are used similarly.

PIPERAZINA.—Piperazine.

Piperazidine; Ethylene-imine; Diethylene-diamine; Dispermine; Arthriticine.

Formula, $(C_2H_4NH)_2 = C_4H_{10}N_2$. Molecular weight, 83.70.

A synthetical compound, at one time supposed to be identical with spermine, but found to differ from the same both in chemical and physiological action.

Preparation.—When ammonia is allowed to act upon ethylene bromide or chloride, a mixture of salts of different bases is obtained, consisting of ethylene diamine, triethylene diamine, diethylene triamine, tetraethylene triamine, and diethylene diamine. In order to separate the last-named base the solution of the mixed salts is treated with an excess of sodium or potassium nitrite and heated to 60° to 70° C. (140°–158° F.),

which causes dinitrosopiperazine to separate as a scaly crystalline mass; this is soluble with difficulty in cold, but readily soluble in hot water, and melts at 154° C. (309.2° F.). This compound, when treated with concentrated acids or reducing agents, yields ammonia and salts of piperazine, from which the pure base is obtained by distillation with alkalies. It is prepared commercially by a number of patented processes—by reduction of ethylene oxamide with zinc dust or metallic sodium (Schering's), and from aromatic disulphone-piperazides by heating with sulphuric acid and subsequent treatment with powdered sodium hydroxide (Marckwald and Haltz).

Properties.—Piperazine occurs in the form of colorless crystalline masses possessing a faint but characteristic odor. Crystallized from water it forms lustrous glassy tablets. When pure it melts at 104° C. (219.2° F.) and boils at 145° C. (293° F.). It is very hygroscopic, absorbing water and carbon dioxide from the atmosphere with avidity. It is soluble in water, and somewhat less so in alcohol, the solutions having an alkaline reaction. It forms a crystalline hydrate ($6H_2O$), which melts at 44° C. (111.2° F.), and which on distillation yields increasing proportions of diethylene-diamine until above 135° C. (275° F.) the anhydrous base is obtained (P. E. Berthelot). The carbonate melts at 162° to 165° C (323.6°–329° F.). It is a strong base, forming crystallizable salts with acids. Its aqueous solution yields precipitates with solutions of mercuric chloride (white), Nessler's Solution (white), cupric sulphate (light blue), picric acid (lemon yellow, crystalline), and a grayish precipitate with tannic acid. In solution acidulated with hydrochloric acid it yields a brick-red precipitate with solution of potassium-bismuth iodide, and yellow crystalline precipitates with platinic chloride and gold chloride. Aqueous solution of chromic acid is without effect on piperazine, but potassium permanganate oxidizes it even in the cold. In contact with uric acid it forms piperazine urate, soluble in 50 parts of water, whereas lithium urate requires 368 parts of water for solution. It is excreted by the urine. Piperazine may be detected in urine by adding a slight excess of sodium hydroxide, heating the mixture, and after cooling and removing the precipitated phosphates by filtration, acidulating with hydrochloric acid and precipitating the piperazine with solution of potassium-bismuth iodide. The brick-red precipitate forms characteristic microscopical crystals.

Action and Uses.—Owing to its property of combining with uric acid to form a urate of piperazine, which is soluble in 50 parts of water, piperazine is used in the uric-acid diathesis for the purpose of preventing the formation of renal and vesical calculi, and also for the relief of irritation of the bladder due to an excess of uric acid in the urine. If calculi have already formed, it is doubtful if piperazine can cause their solution or disintegration, though it may sometimes dissolve uric-acid gravel. Its reputation as a valuable remedy in gout has not been sustained, although it seems to do good in some cases for a short time. A 1 per cent. solution of piperazine has been injected into gouty deposits with the hope of bringing about their solution, but this method of using the drug is both painful and valueless. Ordinary medicinal doses produce no untoward effects, but after large doses tremors, clonic spasms, and general depression have occurred. It is too hygroscopic to be dispensed in powder, capsule, or pill, and its aqueous solution readily decomposes. The menstruum in which it keeps best is composed of 20 parts of alcohol and 80 parts of water. The dose is from 15 to 30 grains (1–2 Gm.) a day, diluted with a large quantity of plain or carbonated water.

Allied Salts.—Piperazine Cinchonate. Sidonal.—*Chinasaures Piperazin*, G. $C_4H_{10}N_2(C_7H_{12}O_6)_2$.—A colorless crystalline powder having an acid taste and reaction, and melting at 168° to 171° C. (334.4°–339.8° F.). It is readily soluble in water.

Dimethylpiperazine Tartrate.—*Lycetol.* $C_6H_{14}N_2C_4H_6O_6$.—A white to colorless crystalline powder, having an acid reaction. It is readily soluble in water, and melts at 250° C. (482° F.). Lycetol is used for the same purposes as piperazine. It is less hygroscopic than the latter drug, and its aqueous solution is more stable. The dose is from 15 to 30 grains (1–2 Gm.) a day, well diluted in carbonated water.

Ethylene-ethynyl-diamine.—*Methylglyoxalidine. Lysidine.* $C_4H_8N_2$.—A monatomic base of strong alkaline reaction, forming colorless hygroscopic crystals which are readily soluble in water, alcohol, and chloroform. Lysidine melts at 105° C. (221° F.) and boils at 195° to 198° C. (383°–388.4° F.). With uric acid it forms a urate which is soluble in 6 parts of water. It gives a reddish-yellow precipitate with potassium bismuth iodide, a lemon-yellow precipitate with phosphomolybdic acid, and a brown precipitate with solution of iodine in potassium iodide. It is claimed that lysidine possesses five times the power of piperazine as a uric-acid solvent. It occurs in the market in a 50 per cent. solution. The dose is from 15 to 60 grains (1–4 Gm.) a day, in an excess of carbonated water.

PIPERINA, *U. S.*—Piperine.

Pipérine, Fr.; *Piperin*, G.

Formula, $C_{17}H_{19}NO_3$ or $CH_2O_2.C_6H_3.CH,CH,CH,CH,CON.C_5H_{10}$. Molecular weight, 283.04.

A feebly basic principle obtained from pepper, and occurring also elsewhere in plants of the family *Piperaceæ*.

Origin.—Piperine was discovered by Oerstedt (1819), and obtained pure by Pelletier and Poutet (1820). It has been prepared from black, white, and long pepper, and by Stenhouse (1855) from the fruit of *Cubeba Clusii*, Miquel.

Preparation.—It is most readily prepared from the alcoholic extract of white pepper by treating it with potassium hydroxide solution, which dissolves the resin, washing the residue with water, and purifying it by repeated crystallization from alcohol. On neutralizing the potassium hydroxide solution with an acid the pungent resin is obtained. Wittstein's process is as follows: 16 parts of black pepper are exhausted with cold water, and afterward with alcohol; the alcoholic extract is washed with water, digested with alcohol and 1 part of slaked lime, and the solution concentrated; the crystals are purified by recrystallization and treatment with animal charcoal. The yield varies between 5 and 9 per cent.

Piperine has been prepared synthetically (Rügheimer, 1882) by effecting the recombination of piperidine with piperic acid.

Properties.—Pure piperine crystallizes in colorless flat, four-sided prisms of a glassy lustre and is almost tasteless. As usually met with, it is of a yellowish color, inodorous, and has at first a slight, but on continued mastication or in alcoholic solution a sharp, peppery taste. It remains unaltered on exposure, dissolved in alcohol, has a neutral reaction to test-paper. "Insoluble in water; soluble at 25° C. (77° F.) in 15 parts of alcohol, and at 60° C. (140° F.) in 4.4 parts; also soluble at 25° C. (77° F.) in 36 parts of ether and in 1.7 parts of chloroform. It melts at 130° C. (266° F.). Upon ignition, it emits alkaline vapors, and is completely consumed. On adding a crystal of piperine to sulphuric acid containing about ½ its volume of solution of formaldehyde, a permanent bright-green solution is obtained. On adding a crystal to sulphuric acid containing a fragment of potassium dichromate, it turns at once purple, and on stirring, dissolves, forming a reddish-brown solution, which becomes dirty green on addition of water. On adding a crystal to sulphuric acid containing a trace of selenous acid, it turns brown, changing at once to violet, and dissolves, forming a brown solution changing to green. When heated with nitric acid, piperine turns, first, orange, then red, and the acid acquires a yellow color, deepening to reddish as the crystals dissolve. On adding to this solution an excess of potassium hydroxide test-solution, the color is at first yellow, but upon boiling it becomes blood red."—U. S. Sulphuric acid colors it blood red, the color disappearing on the addition of water, leaving the piperine unaltered if the action of the acid has not been prolonged (Pelletier). The solution of piperine in sulphuric acid is yellow, becoming dark brown, and finally green brown (Dragendorff). Piperine is a very weak base, and its salts are decomposed by water; crystallizable double salts, soluble in alcohol, may be obtained with the chlorides of mercury, platinum, and cadmium. By dry distillation with soda-lime piperidine is obtained. Boiled with alcoholic solution of potassium hydroxide, piperine was found by Babo and Keller (1856) to be resolved into *piperic acid*, $C_{12}H_{10}O_4$, and *piperidine*, $C_5H_{11}N$. Piperic acid crystallizes in the form of hair-like yellowish needles which fuse at 215° C. (419° F.), and at a higher temperature volatilizes partly unaltered, at the same time giving off a coumarin-like odor. Piperidine is a colorless liquid of an ammoniacal and pepper-like odor, and when largely diluted of a bitter taste. It boils at 106° C. (222.8° F.), has a strong alkaline reaction, dissolves freely in water and alcohol, and yields with acids crystallizable salts; the piperate of piperidine crystallizes in silky scales, which on being heated give off a part of the alkaloid. Ladenburg (1884) obtained a small quantity of piperidine synthetically by treating an alcoholic solution of pyridine with sodium. This method has developed into a commercial process.

Action and Uses.—In the dose of from 3 to 6 grains (0.20–0.40 Gm.), three times a day, piperine has been used as an antiperiodic in malaria without much success.

Derivative Compounds.—Piperonal.—*Heliotropin*. $C_8H_6O_3$.—By boiling piperine for some time (24 hours) with an alcoholic solution of potassium hydroxide, potassium piperate is

formed and crystallizes in shining prisms; this is dissolved in 40 to 50 parts of hot water and slowly mixed, constantly stirring, with a solution of potassium permanganate (2 parts of the latter salt to 1 of the piperate). The resulting magma is put on a strainer and repeatedly washed with hot water until the odor of heliotropin entirely disappears; the united liquids are distilled, and from the first portions of the distillate the larger portion of piperonal separates in crystals: the remainder is obtained by shaking the distillate with ether. Piperonal occurs in small white crystals, soluble in about 600 parts of cold water, and very readily soluble in alcohol and ether. It has been used as an antiseptic and antipyretic in doses of from 10 to 15 grains (0.65–0.97 Gm.) every 3 hours, but is chiefly employed in perfumery.

PISCIDIA.—Piscidia.

Jamaica or *White Dogwood*, E.; *Piscidie*, G., Fr.; *Bois enivrant*, Fr.; *Colorin de peces*, Sp.; *Mulungu*, *Murungu*, Braz.

The bark of the root of *Ichthyomethia Piscipula* (L.) Kuntze (*Erythrina P.* L.; *Piscidia P.* Sargent; *Piscidia Erythrina* Jacq.; *P. toxicaria* Salisb.; *P. inebrians* Medic. —Fam. *Leguminosæ*).

Origin.—The Jamaica Dogwood is a small tree of the West Indies, extending into southern Florida, somewhat resembling the locust. It bears unequally pinnate leaves, paniculate racemes of whitish and deep-red flowers, and 4-winged legumes. It yields a useful timber and the bark is employed as a fish poison.

FIG. 320.

Piscidia, root-bark: A, outer, B, inner surface (⅔ Nat.).

Description.—In irregular quills or curved or flattish sections or strips of variable size and 2 to 6 Mm. ($\frac{1}{12}$ to $\frac{1}{4}$ In.) thick; outer surface varying from pale brownish white to bright orange brown, roughish-wrinkled and somewhat fissured, or, by the removal of the corky layer, dark ash-gray with a brownish or blackish tint, and slightly wrinkled and ridged; inner surface brownish, either smooth or more or less fibrous; either surface may exhibit patches of a peculiar, somewhat metallic bluish-green discoloration; fracture tough-fibrous; transverse section exhibiting the transversely elongated bast-bundles arranged in irregular circles and radial rows; odor narcotic, somewhat opium-like; taste at first slight, becoming bitter and acrid.

The stem-bark is less warped and knotty, in more regular strips, and possesses a green chlorophyll layer.

Constituents.—Besides starch, fat, resin, etc., without tannin, the neutral body *piscidin* ($C_{29}H_{24}O_8$) occurs and may be extracted from the concentrated tincture by treating it with lime, filtering, adding a little water and crystallizing; after recrystallization from alcohol it forms colorless prisms, which melt at 192° C. (277.6° F.), are insoluble in water, slightly soluble in ether and in cold alcohol, and easily soluble in benzene and chloroform. Investigation is yet necessary to prove that piscidin possesses in full the active properties of the drug.

Action and Uses.—Piscidia is used in medicine for its anodyne and hypnotic properties. Its power of relieving pain does not compare with that of opium, but it produces fewer unpleasant after-effects than does the latter drug. From the studies of Ott and Nagle it appears that the analgesia produced by the drug is due to its action upon the sensory centres, not upon the sensory nerves. It has no effect upon motor nerves. It slows the pulse by directly depressing the cardiac muscle, and raises blood pressure by stimulating the vasomotor centres. In full doses it increases the secretion of the salivary glands and skin. In dysmenorrhœa, due to spasm of the cervix uteri, piscidia has produced good results, and it has been used with varying success in neuralgia, toothache,

headache, nervous irritability, and insomnia due to pain. The dose of the unofficial extract is from 2 to 10 grains (0.12–0.60 Gm.); of the fluid extract, from ½ to 2 drachms (2–8 Cc.).

The bark of *Erythrina corallodendron* L., the *Brazilian coral tree*, and that of *E. Mulunga* Mart., are also known in Brazil as Mulungu or Murungu, and are similarly employed. The leaves are also employed as a laxative and diuretic.

PIX BURGUNDICA, *Br.*—Burgundy Pitch.

Poix de Bourgogne, P. des Vosges, P. jaune, Fr. Cod.; *Poix blanche*, Fr.; *Burgunder Harz (-Pech)*, G.; *Pece di Borgogna (dei Vosges), P. Bianca*, It.; *Pez de Borgona, P. amarilla, P. blanca*, Sp.; *Pez de Borgonha, Resina de Abeto*, Port.

The prepared resinous exudation from the spruce fir, *Abies Abies* (L.) Rusby (*Pinus A.* L.; *P. excelsa* Lam.; *P. Picea* Du Roi; *Picea excelsa* Link.—Fam. *Pinaceæ*), a tall and handsome evergreen of the mountains of central and southern Europe, and frequently cultivated for ornament.

The turpentine, known as *Jura Turpentine*, is obtained by making incisions in the bark and collecting the exudate after concretion. Tschirch and Bruening give its composition as volatile oil, 32 to 33 per cent.; *picea-pimarinic acid* ($C_{20}H_{20}O_2$), 2 to 3 per cent.; *picea-pimaric acid* ($C_{20}H_{30}O_2$), 1.5 to 2 per cent.; *α-* and *β-pimarolic acids* ($C_{25}H_{44}O_2$), 48 to 50 per cent.; *resene* ($C_{21}H_{36}O$), 10 to 12 per cent.; traces of succinic acid, coloring-matter, and bitter principle. This, by melting in water and straining, is converted into the substance here considered. It is prepared in many parts of Europe, but not in Burgundy.

Description.—Hard, yet gradually taking the form of the vessel in which it is kept; brittle, with a shining, conchoidal fracture, opaque or translucent, reddish brown or yellowish brown, odor agreeably terebinthinate; taste aromatic, sweetish, not bitter.

It is almost entirely soluble in glacial acetic acid or in boiling alcohol, and partly soluble in cold alcohol.

Composition.—Burgundy pitch consists chiefly of resin. With it are about 5 per cent. of volatile oil, apparently isomeric with oil of turpentine, and a variable amount, up to 10 per cent., of water absorbed during the treatment of the turpentine.

Substitution.—An artificial substitute, variously prepared from common resin, has been extensively supplied. It bears but a poor resemblance to the genuine.

Pharmaceutical Preparations.—Burgundy Pitch Plaster, Cantharidal Pitch Plaster.

Action and Uses.—Applied to the skin in the form of a plaster, Burgundy pitch produces itching, redness, and mild irritation. Upon a delicate skin it may occasion a papular or vesicular eruption, and in some instances a still more severe degree of irritation terminating in vesication, pustulation, or ulceration. It is a fairly useful external remedy in lumbago, chronic rheumatic pains, chronic bronchitis, and pleurisy.

Pix Canadensis.—*Canada*, or *Hemlock pitch* (*Poix de Canada*, Fr.; *Canadisches Pech*, G.; *Pez de Canada*, Sp.), is the prepared resinous exudation from the common Hemlock, Hemlock or Weeping spruce, or Spruce pine, *Tsuga Canadensis* (L.) Carr, (*Pinus C.*—L.; *Abies C.*—Mx.) of northern North America, a good-sized and handsome tree. The oleoresin is obtained either like ordinary turpentine, from small boxes cut into the trunk, or by cutting out and boiling the knotty pieces and skimming off the turpentine from the surface of the water. In either case the product is purified by melting and straining. It then hardens into masses which are reddish brown and opaque or with the superficial portion translucent, brittle at ordinary temperatures, yet taking the form of its container, breaking with a shallow, conchoidal, and glassy fracture and a lighter-colored inner portion, softened by the heat of the hand and of a weakly terebinthinate odor and a terebinthinate taste. It is commonly adulterated to a large extent with common resin, and the artificial compounds mentioned under Burgundy Pitch are also sold for it. The composition of Canada Pitch is identical, for all practical purposes, with that of the preceding. The precise nature of its volatile constituents has not been investigated.

PIX LIQUIDA, *U. S., Br., P. G.*—Tar.

Resina empyreumatica liquida.—Pyroleum Pini Scand.; *Goudron végétal,* Fr. Cod.; *Theer,* G.; *Brea Alquitran,* Sp.; *Catrame vegetale,* It.; *Alcatrao (Carburolao) do Pinheiro, Breu Cru,* Port.

A product obtained by destructive distillation from the wood of *Pinus palustris* Mill. and of other species of *Pinus* (Fam. *Pinaceæ*).

Official in all pharmacopœias, most of which include Pines and Firs as the source, though the Austrian requires it from the Beech (*Fagus*) only.

Origin and Preparation.—The species named under TEREBINTHINA, together with *P. rigida* Mill., the *Pitch, Torch, Fat, Candlewood, Hard* or *Yellow pine,* yield most of the American tar, while *P. sylvestris* L. and *Larix Siberica* Ledeb. yield most of the European.

Most of the wood used for this purpose consists of stumps, roots, and other waste materials of the lumberman. It is said that the dead portions of the tree become more abundantly charged with the resinous matters than the living, and the lumbermen even believe that after the entire tree is dead, the amount continues to increase.

The essential feature in tar-distillation is that the pile of wood be slowly and imperfectly burned from the top downward, the tar being successively driven out of the wood next underneath the burning point and running downward and out at the bottom, where it is collected. This is sometimes performed in furnaces or stills, but the product is not quite the same as that produced from the extemporized stacks of our southern distillers, the latter tar being useful for some purposes for which the former is not. In making these stacks, a circular mound of earth, about 20 feet in diameter, hard-packed and clay-coated, is first formed and surrounded by a ditch from which the tar is to be conveyed away. As the wood is piled upon the mound the diameter of the pile gradually increases to about 25 feet at the top, some 10 or 12 feet high. The top is then covered with a layer of pine-needles, the sides of the stack are protected in some way against a free current of air, and the top is ignited. The tar is barrelled as fast as it runs away. Such a stack burns for a week or 10 days and yields 100 barrels or more of tar.

Description.—Tar is a thick, viscid, semifluid mass, heavier than water, of a deep blackish-brown color, transparent in thin layers if free from water, and has an unpleasant empyreumatic odor and a sharp and bitter taste. On standing, it usually separates a granular crystalline matter consisting of *pyrocatechin* (catechol), and often assumes the consistence of thick honey. It has an acid reaction, which, together with a light-brown color and sharp bitterish taste, is imparted to water agitated with it. On the application of heat, water and acetic acid distil over, together with a yellow volatile oil. Tar is soluble in alcohol, ether, chloroform, fixed and volatile oils, and caustic alkalies. The aqueous infusion of tar is colored transiently green by ferric chloride, due to the presence of pyrocatechin, and with lime-water acquires permanently a brown-red color. An 0.1 per cent. solution of copper acetate colors the petroleum ether extract greenish.

Composition.—Tar is of very complex composition, which varies with the kind of wood, the amount of resins present therein, and the care with which it has been prepared. It contains *acetic acid,* *acetone,* *methyl alcohol,* *mesit,* $C_6H_{12}O_2$, *toluene,* C_7H_8, *xylene,* C_8H_{10}, *cumene,* C_9H_{12}, *methene,* C_9H_{12}; likewise *phenol,* C_6H_6O, *cresol,* C_7H_8O, *creosote, paraffiin, naphtalene, pyrene,* $C_{16}H_{10}$, *chrysene,* $C_{18}H_{12}$, *retene,* $C_{18}H_{18}$, and others. Of the compounds mentioned, the first series up to methene pass over with the light tar oil, which also contains Reichenbach's *eupion,* a very light oily product of low boiling-point. The *heavy tar oil* contains the other compounds named, and in addition *cedriret, kapnomor, picamar,* and *pittakal,* which names were introduced by Reichenbach to designate various substances not yet obtained in a pure state. After distilling from tar the light and most of the heavy oil, a substance is left behind which is still recognized in some pharmacopœias as:

PIX NAVALIS, s. *Pix nigra, P. solida, Resina pina empyreumatica.—Pitch, Black pitch,* E.; *Poix noire,* Fr. Cod.; *Schwarzes Pech, Schiffspech,* G.; *Pez negra,* Sp.—It is a black, resinous, brittle mass, which becomes soft when held in the hand, and has the odor of tar.

Pharmaceutical Preparations.—ALKALINE SOLUTION OF TAR, COMP. ELIXIR OF TAR, GLYCERITE OF TAR, TAR MIXTURE, COMP. TAR OINTMENT, COMP. TAR PLASTER, N. F.; SYRUP OF TAR, TAR OINTMENT, U. S. P.; WINE OF TAR, N. F.

Action and Uses.—The employment of tar in chronic pulmonary affections and in various skin diseases has descended from ancient times. It is an efficient expectorant, used in the treatment of subacute or chronic bronchitis, given in the official syrup, the wine (N. F.) or tar-water. Tar-water is made by shaking 1 part of tar in 4 parts of water several times during 24 hours, decanting, and filtering. It is given in the dose of from 1 to 2 pints (480–960 Cc.) a day as a drink. In dry, scaly skin eruptions, such as psoriasis and lepra, tar, in the form of an ointment, exercises a beneficial effect. Before the tar is applied the scales should be removed by a warm bath. In some cases of persistent eczema, when the skin has become dry, rough, and thickened, tar ointment is often used with advantage when all other remedies have failed. The official ointment may severely irritate a delicate skin and should be diluted before using. Tar should not be applied to the face, as it will stain the skin. The dose of tar is from 1 to 3 grains (0.05–0.20 Gm.) in pills; of the Syrupus Picis, 1 to 4 drachms (4–16 Cc.); of the Vinum Picis (N. F.), 2 to 8 drachms (8–30 Cc.).

Other Tars.—*Beech-wood* (*Fagus*) *Tar*, which is greatly preferred for the manufacture of creosote because of the great richness of the latter in *guaiacol*, is only incompletely soluble in turpentine oil, ether, and chloroform, and does not respond to the last-mentioned test for PIX LIQUIDA.

Birch tar, *Pix betulæ* or *P. betulinum*, *Oleum betulæ empyreumaticum*, or *Oleum rusci* (*Birkentheer*, *Birkenœl*, G.; *Huile russe*, *Huile de bouleau*, Fr.) is prepared in Russia from the wood and bark of *Betula alba* L. (see also under BETULACEÆ). It resembles wood-tar in appearance, but remains liquid and has a peculiar penetrating odor. Sobrero obtained from it a yellowish volatile oil ($C_{10}H_{16}$), of an agreeable odor, like that of birch-bark, and boiling at 156° C. (312.8° F.). (For *Juniper Tar*, see OLEUM CADINUM.)

PLANTAGO.—Plantain.

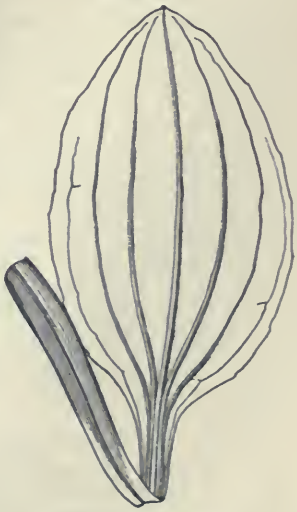
Common, *Door-yard*, *Large-leaved*, *Broad-leaved*, *Round-leaved*, *Greater*, or *Bird-seed plantain*, *Hen-plant*, *Way-bread*, E.; *Grosser Wegerich*, *Sanohr*, G.; *Plantain*, Fr.; *Lauten*, Sp.

The root, the leaves, or the leaves and flower-spikes of *Plantago major* L. (Fam. *Plantaginaceæ*).

Plantago is not official in any pharmacopœia, and is far less used than formerly.

Origin and Description.—The Broad-leaved plantain is a native of Europe and Asia and occurs abundantly in the United States as a common door-yard weed, covering large patches, to the exclusion of about all else. It grows from a very short rhizome, which bears below a great number of long, straight, capillary, yellowish roots, and above a large radical rosette of leaves and a few long, slender, densely flowered spikes. The leaves are ovate, blunt, abruptly contracted at the base into a long, broad, channelled petiole. The blade is 10 to 25 Cm. (4 to 10 In.) long and about two-thirds as broad, usually smooth, thickish, strongly 5- to 11-ribbed, the ribs having a strongly fibrous structure, the margin entire or coarsely and unequally dentate-serrate. The spikes are erect, strongly and long-peduncled, about as long as the leaves, 6 to 8 Mm. ($\frac{1}{4}$ to $\frac{1}{3}$ In.) thick, and usually blunt. The flowers are somewhat purplish green, the calyx 4-parted, the small corolla bell-shaped and 4-lobed, the stamens 4. The fruit is a 2-celled capsule, not enclosed in the perianth, dehiscing transversely at about the middle and containing 4 to 16 seeds. The drug is without odor and has only a slightly astringent, bitterish, and saline taste.

FIG. 321.



Plantago (½ Nat.).

Constituents.—No special constituents have been encountered, a little resin, a very small amount of a bitter principle, citric and oxalic acids, and ordinary plant constituents having been reported.

Action and Uses.—Plantago has been thought to possess curative properties in the treatment of many diseases, including inflammations of the skin, malignant ulcers, inter-

mittent fever, etc., and is still used to some extent. Applied to a bleeding surface the leaves are of some value in arresting the hemorrhage, but they are useless in internal hemorrhage. It is a very feeble remedial agent.

Allied Species.—The genus *Plantago* L. contains more than 200 species, 25 or 30 of which have been reported as in domestic use, though none possesses active properties. Several, like that above considered, are common weeds and are used like or indiscriminately for it. Of these, the most important is *P. lanceolata* L., native of the same region and commonly known as *Black, Long, English,* or *Snake plantain, Rib-* or *Ripple-grass, Ribwort, Black-jack, Jackstraws, Hen plant, Windles,* E.; *Spitzer Wegerich* or *Wegetritt,* G.; *Plantain,* Fr.; *Lauten,* Sp. This is a very dark-green, hairy, slender perennial, growing much taller than the last. Its leaf-blades rarely reach an inch in breadth, are 3- to 5-ribbed, gradually narrowed into the petioles, which are often more than a foot long, the scapes often more than 2 feet long and terminating in ovoid or cylindrical, blunt, dense spikes, ½ to 3 or 4 inches long and ⅛ to ¼ inch thick. The constituents are similar to those of the last. The other species which are commonly used in the United States are similar to *P. major.* Among the homœopaths it is fancied that only the red-stemmed plants are active. In Europe, as well as in southern Asia, *P. Psyllium* L. (*P. Afra* L.), known as *Psyllion, Psyllios, Baraguthi,* etc., is used similarly to *P. major.* The seeds are also used, like flax-seed, for their large yield of mucilage.

In India, the seeds of *P. ovata* Forsk. (*P. Ispaghula* Roxb.), the *Uthamujiram, Ispughul, Spugul, Isafgul,* or *Kaseni,* are used as an antidysenteric and are largely adulterated with various Labiate fruits, especially those of *Ocimum. P. decumbens* Forsk., of South Africa, is regarded by some as the wild plant of which the preceding is a cultivated variety. The seeds of *P. arenaria* Waldst. et Kitt., somewhat smaller, black, and less glossy, and those of *P. Cynops* L., somewhat larger and lighter brown, are used similarly.

PLATINUM.—Platinum.

Platine, Or blanc, Fr.; *Platin,* G.

Symbol, Pt. Bivalent and quadrivalent. Atomic weight, 193.3.

Origin and Preparation.—This metal was apparently observed as early as the sixteenth century, but was more fully described and investigated after the middle of the eighteenth century by Watson, Scheffer, Lewis, Bergman, and others. It is found pure and in combination with palladium, rhodium, osmium, iridium, and other metals in California, in various parts of South America, in the Ural Mountains and other parts of Europe, and in Asia and Africa. It is often met with in auriferous sand, and occasionally in lead, iron, and other ores. The ore is treated with strong hydrochloric acid, well washed by elutriation, the residue treated with nitro-muriatic acid, the acid solution evaporated, redissolved in water, and precipitated with ammonium chloride; on igniting the resulting ammonio-platinic chloride, platinum is obtained in a spongy condition.

Properties.—Spongy platinum is gray, soft, and porous, and fusible only by the aid of the oxyhydrogen blowpipe. The metal is of a silver-white color and metallic lustre, is soft like copper, possesses considerable malleability and ductility, and at a white heat may be forged. Platinum resists the action of most chemicals except mixtures of nitric with hydrochloric or hydrobromic acid, in which the liberated chlorine or bromine dissolves the metal. Caustic alkalies, lithium chloride, and a mixture of potassium nitrate and hydroxide at high temperatures corrode platinum appreciably, as do also alkali cyanides.

Many metals form low-melting alloys with platinum, and therefore such metals, either in the free state, as oxides or as easily reducible compounds, should never be heated in platinum vessels. Lead, bismuth, tin, cadmium, and antimony are among such metals. Mixtures of carbon and silica heated in platinum cause the latter to become brittle by absorption of carbon. Hypophosphites, phosphates with carbon, thiosulphates, and sulphides corrode platinum when heated with it, forming phosphide or sulphide.

Finely divided platinum, as platinum sponge or platinum black, which is obtained by reduction from its salts, has a marked absorptive power for gases, especially oxygen. One volume of platinum black absorbs several hundred volumes of oxygen, by which it becomes a powerful oxidizer; for example, it causes hydrogen to ignite, oxidizes sulphur dioxide to sulphuric acid, ammonia to nitric acid, etc.

Platinum is used chiefly for making chemical apparatus, as crucibles, dishes, etc., and in electrical apparatus; its salts are used as reagents in chemical operations, in photog-

raphy, and to give colors to ceramics. With oxygen it forms a monoxide, PtO, and a dioxide, PtO_2, which are reduced to the metal at a red heat. The platinous salts are brown, red, or colorless; the platinic salts have a yellow or brown color.

PLATINI CHLORIDUM.—*Platinic chloride*, E.; *Perchlorure de platine*, Fr.; *Platinchlorid*, G. $PtCl_4.5H_2O$. Molecular weight, 423.42.—It is prepared by dissolving 3 parts of platinum in a mixture of 16 parts of hydrochloric and 7 parts of nitric acid, evaporating the solution nearly to dryness, redissolving in hydrochloric acid, heating to expel the nitric acid, and evaporating at a moderate heat to dryness, when a red crystalline mass is left, which may be obtained from water in handsome red crystals containing 46 per cent. of platinum. When heated to 100° C., these lose $4H_2O = 16.9$ per cent., and turn brown. If the salt is permitted to crystallize in the presence of free hydrochloric acid, brownish-red needles are obtained which have the composition $PtCl_4.2HCl.6H_2O$, and contain 38 per cent. of platinum. This is the compound usually met with in commerce. Heated to above 110° C. it parts with hydrochloric acid and chlorine, and near 225° C. (437° F.) dark-brown platinous chloride is left. Platinum chloride dissolves readily in alcohol and water, yielding reddish-yellow liquids which precipitate the potassium and ammonium chlorides, forming K_2PtCl_6 and $(NH_4)_2PtCl_6$.

PLATINI ET SODII CHLORIDUM.—*Sodium platino-chloride*; *Sodium and platinum chloride.*—The double salt, $2NaCl.PtCl_4.6H_2O$, crystallizes in light-red prisms, and is freely soluble in water and alcohol. For medicinal purposes a preparation containing an excess of the sodium salt is used, made by dissolving 3 parts of platinic chloride and 5 parts of sodium chloride in water, and evaporating to dryness, stirring continually. It is an orange-yellow powder having a saline and metallic taste.

PLATINI IODIDUM.—*Platinic iodide.* PtI_4.—A solution of platinic chloride is mixed with a solution of an equivalent quantity of potassium iodide, the deep-red mixture nearly neuralized with potassium carbonate, and digested for an hour. The precipitate, after washing and drying, is a brown-black amorphous and tasteless powder, insoluble in water, but soluble in potassium carbonate and iodide with a pale-red color.

PLATINI ET POTASSII CYANIDUM.—*Potassium platino-cyanide.* $2KCN.Pt(CN)_2.3H_2O$.—It is best prepared, according to Meillet, by mixing rather concentrated solutions of 1 part of exsiccated platinic chloride and 2 parts of potassium cyanide, and heating the mixture until the precipitate is redissolved: ammonium carbonate and nitrogen are given off, and on cooling the double salt crystallizes. It forms long needles and prisms, having in different positions a yellow or bright-blue color, and when exposed to the air becoming opaque and rose-red. The salt is freely soluble in hot water, and its solution precipitates cupric salts greenish blue, mercurous nitrate bright blue, and ferrous salts bluish-white.

PLATINI ET BARII CYANIDUM.—*Platinum and barium cyanide; Barium platinocyanide.* $Ba(CN)_2.Pt(CN)_2.4H_2O$.—This salt occurs in large rhombic crystals, appearing green or yellow, according to the position in which it is viewed. It is used in preparing Röntgen fluoroscopes, because of its power to become luminous when Röntgen rays pass through it.

Action and Uses.—The action on the economy of the compounds of platinum was studied by Hoefer in 1841. The results of his investigation show that the chlorides of this metal are as poisonous as those of mercury and gold. A strong solution of platinum chloride applied to the skin produces itching followed by an eruption, but the double chloride of platinum and sodium has no such effect. Internally the chloride irritates the stomach and causes headache, even in small doses, while the double salt is not so irritating in its action. Both salts have been used in the treatment of syphilis, the chloride in the inveterate constitutional forms of the disease and the chloride of platinum and sodium in the primary stages. The dose of either preparation is from $\frac{1}{8}$ to 1 grain (0.008–0.06 Gm.), several times a day, in pill or mucilage.

PLUMBI ACETAS, *U. S., Br.*—Lead Acetate.

Plumbum aceticum, P. G.; *Saccharum saturni.—Sugar of lead*, E.; *Acétate de plomb, Sucre de saturne*, Fr.; *Essigsaures Bleioxyd, Bleiacetat, Bleizucker*, G.

Formula, $Pb(C_2H_3O_2)_2 + 3H_2O$. Molecular weight, 376.15.

Lead acetate should be kept in well-closed bottles, and be not less than 99.5 per cent. pure.—U. S.

Preparation.—No detailed methods are given in the pharmacopœias. The salt may be prepared by dissolving 1 part of lead oxide (litharge) in 2 parts of warm 30 per cent. acetic acid, filtering, and crystallizing.

The process described is frequently followed on a large scale. Sometimes, however, metallic lead is dissolved in acetic acid, which requires to be done in the presence of air, since the metal is unable to displace the hydrogen of the acid. Plates of lead are placed endwise in open vessels containing acetic acid, one-half of their length projecting above the liquid, and as fast as the metal under these conditions is oxidized by the oxygen of the air, it is dissolved, so that the formation of the salt in both cases is the result of the action between plumbic oxide and acetic acid, water being formed at the same time: $PbO + 2C_2H_4O_2$ yields $Pb(C_2H_3O_2)_2 + H_2O$. To obtain handsome and well-defined crystals the solution must have a very distinct acid reaction; if it is permitted to become faintly acid or neutral, a portion of the salt forms small granular crystals agglomerated into soft cauliflower-like masses, containing perhaps a basic lead compound.

Large quantities of lead acetate are now made from metallic lead by placing the same in granular form in large open stoneware cylinders and allowing strong acetic acid to fall upon it in drops from a cask provided with a glass outlet-tube and a multiple drip-cock attachment. During the operation, heat is developed as the acid slowly trickles over the metal, and under the influence of air the lead is gradually dissolved in the form of basic lead acetate. The solution is allowed to collect in the lower part of the cylinder, and is thence transferred to large receptacles, where it is exactly neutralized with acetic acid, and the solution of normal lead acetate then set aside to crystallize. Purified lead acetate for dispensing purposes is prepared in granular form by dissolving the large crystals in water, filtering and evaporating the solution with frequent stirring, so that small crystals may be produced. For uses in the arts large quantities of impure lead acetate are prepared from wood-vinegar, and vary in color from various shades of brown to pale red and white.

Properties.—Pure lead acetate crystallizes in colorless, glossy, transparent, or translucent prisms, which are often tabular and have an acetous odor and a sweet astringent and metallic taste. It is slightly efflorescent in the air, and on continued exposure is superficially converted into lead carbonate. When heated to 40° C. (104° F.) the salt loses its water of crystallization (14.25 per cent.). It fuses at 280° C. (536° F.) with the loss of acetic acid, and, when strongly heated, it is completely decomposed, with the evolution of carbon dioxide and acetone, and leaving a residue of finely divided metal mixed with oxide and carbonate. It also loses its water of crystallization over sulphuric acid and by the action of absolute alcohol, crystallizing from this liquid in an anhydrous condition; but when dissolved in hot 90–95 per cent. alcohol the salt crystallizes on cooling with $2H_2O$. It dissolves at 25° C. (77° F.) in 2 parts, and at the boiling-point in ½ part of water. The solution has a slight acid reaction, and if concentrated and mixed with strong alcohol, gradually separates a portion of the salt in crystals. It dissolves also in about 1 part of boiling and in 30 parts of cold alcohol, U. S. (29 parts P. G.), and is precipitated from this solution as a crystalline powder on the addition of ether. The aqueous solution of the salt has a slightly acid reaction, and yields a black precipitate with hydrogen sulphide test-solution, a yellow one with potassium iodide test-solution, and a white one with diluted sulphuric acid. On heating the salt in the flame of the blowpipe upon charcoal globules of metallic lead are obtained, surrounded by a reddish-yellow incrustation. The salt is decomposed by the mineral and many organic acids, acetic acid being liberated.

Tests.—Lead acetate should yield a clear solution with distilled water. A slight turbidity resulting from the presence of a little carbonate must disappear on the addition of a small quantity of acetic acid. Perfect solubility indicates the absence of sulphate and notable quantities of chloride. The aqueous solution, completely precipitated by hydrogen sulphide, should yield a filtrate which is not precipitated by ammonia and ammonium sulphide (zinc, etc.) or when evaporated to dryness, does not leave any residue (absence of salts of the alkali metals, and those of magnesium, calcium, zinc, and iron). Small quantities of copper would be indicated by the blue color of the filtrate obtained after precipitating the solution of the salt with an excess of ammonia. Potassium ferrocyanide should yield a white precipitate (absence of copper, iron, etc.), and on treating the salt with sulphuric acid in the presence of a crystal of ferrous sulphate a black color should not be produced (nitrate).—U. S. 1 Gm. should require 53.1 Cc. of

tenth-normal sulphuric acid to precipitate the lead completely.—Br. This corresponds to 99.87 per cent., each Cc. corresponding to 0.018808 Gm. of the salt.

Crude lead acetate is recognized in the P. G., which demands that a solution of the salt in 3 parts of water, although it may be opalescent, should yield a white (not a colored) precipitate with potassium ferrocyanide, thus showing the absence of iron and copper. The salt is usually contaminated with varying proportions of basic lead carbonate.

Action and Uses.—A solution of lead acetate applied to mucous membranes or to a broken surface of the skin constringes and blanches the area and forms a white coating of lead albuminate upon it. In medicinal doses it is a sedative astringent, and in overdose produces acute poisoning (see PLUMBUM), which has been followed in some instances by symptoms of chronic lead-poisoning. It is considered a valuable remedy by many practitioners in the treatment of serous diarrhœa and dysentery, especially in the subacute and chronic forms of these diseases. It is usually administered in pill form in combination with opium. As a styptic in internal hemorrhage it is of questionable utility except in those cases in which it comes in direct contact with the bleeding-point, as in hemorrhage from the stomach and intestine. In proportion of 1 to 8 grains (0.06–0.50 Gm.) to the ounce (30 Cc.) of water, it may be injected into the urethra in the treatment of gonorrhœal urethritis, and into the vagina for leucorrhœa. A solution of 1 to 2 grains (0.06–0.12 Gm.) to the ounce (30 Cc.) of distilled water is used as a collyrium in acute and chronic conjunctivitis. An alcoholic solution in the strength of ½ grain (0.03 Gm.) to the ounce (30 Cc.) is a soothing application to the dermatitis produced by poison ivy. The employment of lead acetate has practically been discontinued in the treatment of epilepsy, chorea, hysteria, aneurism, chronic bronchitis, and many other diseases in which it was formerly considered of value. The dose is from 1 to 3 grains (0.06–0.20 Gm.) every 3 to 6 hours.

PLUMBI CARBONAS, *Br.*—Lead Carbonate.

Cerussa, P. G.; *Plumbum carbonicum.*—*White lead, Basic lead carbonate*, E.; *Carbonate de plomb, Blanc de plomb, Céruse*, Fr.; *Bleiweiss, Bleicarbonat*, G.

Formula, $2PbCO_3.Pb(OH)_2 = Pb_3(CO_3)_2(OH)_2$. Molecular weight, 768.91.

Preparation.—When ammonium carbonate solution is added to a solution of a lead salt, normal lead carbonate, $PbCO_3$, is precipitated. Potassium or sodium carbonate precipitates a basic or oxycarbonate, the composition of which varies with the concentration and temperature. The normal carbonate as a pigment has less body than the basic salt which is obtained commercially by two methods.

One method, known as the *Dutch process*, is as follows: Cast sheets of lead are suspended in earthen pots containing a small quantity of vinegar or pyroligneous acid; a number of these pots are arranged in rows, alternating with layers of dung or spent tan, until a shed is filled, which is entirely covered with the same material. A warm and moist atmosphere, charged with carbon dioxide, is thus produced in the shed, favorable for the oxidation of the metal and its conversion by the acetic vapors into basic lead acetate, which is decomposed by the carbon dioxide, yielding white lead and neutral acetate. The latter again unites with a fresh portion of oxide, forming basic lead acetate, which is again acted upon by the carbon dioxide, and the process continues until in the course of a few weeks the lead is completely covered with a thick crust of white lead, which is detached, ground with water, and washed to remove lead acetate and dried. Various modifications of this process have been recommended and are in use, the most important one being that largely used in Austria, where the sheet lead is suspended in wooden boxes, vapors of acetic acid, moisture, and carbon dioxide being supplied in various ways; a number of such boxes are placed in a suitable room, where the temperature is slowly raised from about 25° to 50° C. (77°–122° F.), until after several weeks the conversion is completed.

The other method is known as *Thénard's process*, according to which a solution of lead subacetate is prepared in the usual way, and carbon dioxide passed through it, the filtrate from the precipitate being again used in the preparation of the lead solution. This process has been modified by Benson, so that levigated litharge is mixed with 1 or 2 per cent. of sugar of lead and sufficient water to form a thin paste, which, with frequent stirring, is exposed to the action of carbon dioxide until this ceases to be absorbed; the carbonate is washed with water.

Properties.—Commercial lead carbonate is in pulverulent masses or forms a non-gritty, heavy, white powder, which is not altered on exposure to air unless hydrogen sulphide be present, when it turns black. It is inodorous, and at first tasteless, but gradually develops a slight sweetish and metallic taste. It is insoluble in water and alcohol, but dissolves with effervescence in diluted acetic or nitric acid. The solutions yield with sulphuric acid a white, and with potassium iodide a yellow, precipitate. The white precipitates occasioned in the solution by sodium and potassium hydroxide are soluble in an excess of the precipitant. Heated to 155° C. (311° F.), lead carbonate parts with its water; near 180° C. (356° F.) it begins to lose carbon dioxide and turns yellow, and when heated before the blowpipe upon charcoal it yields globules of metallic lead, surrounded by a reddish-yellow incrustation.

Tests.—Lead carbonate may be adulterated with the sulphates of lead, barium, or calcium, which would be left behind as a white residue upon treatment with dilute nitric acid; only a trifling residue should be left. On adding to this solution an excess of caustic soda, the white precipitate of lead hydroxide at first formed should be completely dissolved (any insoluble portion would indicate the presence of calcium, barium, or strontium, whose hydroxides, contrary to that of lead, are insoluble in caustic alkali), and the alkaline solution should not be rendered permanently turbid on the addition of 1 drop of diluted sulphuric acid (indicating the absence of barium, lead sulphate being soluble in caustic alkali); but on precipitating the solution completely with sulphuric acid the filtrate should be colorless, and should not be precipitated or colored by potassium ferrocyanide (zinc, etc.) or by an excess of ammonia (copper, alumina, P. G.). The solution in diluted nitric acid on being completely precipitated by hydrogen sulphide should yield a filtrate that is not rendered turbid by sulphuric acid.

If 2 Gm. of the salt be dissolved in a mixture of 2 Cc. of nitric acid and 10 Cc. of water, it should not leave more than 0.02 Gm. of residue (limit of insoluble foreign salts). On completely precipitating the solution with hydrogen sulphide, the filtrate should not leave more than a trifling residue on evaporation (limit of salts of the alkalies, alkaline earths, or zinc). If 1 Gm. of the salt be strongly ignited in a porcelain crucible, it should leave a residue of lead oxide weighing not less than 0.85 Gm.

Composition.—White lead is an oxycarbonate, and has approximately the formula given above, in which case it will leave a residue of 86.2 per cent. upon being heated to redness. But the composition may vary from the presence of other oxycarbonates, and the residue left on ignition has been found as low as 83.7 and as high as 86.7 per cent.

A mixture of equal parts of white lead and barium sulphate is sold as *Venetian white; Hamburg white* and *Dutch white* consist of 1 part of white lead to 2 parts and 3 parts respectively of barium sulphate.

Action and Uses.—Lead carbonate is employed externally only. In powder it allays the local irritation due to erythema, erysipelas, intertrigo, and other cutaneous diseases. The official ointment or a thick cream, made by combining the drug with linseed oil, is a soothing application to scalds, superficial burns, and sunburn. As "flake white" it is sometimes associated with other drugs in the manufacture of face powders and cosmetics. In no form should it be applied to the skin for a long time, especially if there is a break in the cutaneous surface, for fear of producing poisoning. Because of its extensive employment in the arts, lead carbonate or white lead is responsible for most of the cases of chronic lead-poisoning and painters' colic.

PLUMBI IODIDUM, *U. S., Br.*—Lead Iodide.

Plumbum iodatum. Iodure de plomb, Fr.; *Jodblei*, G.

Formula, PbI_2. Molecular weight, 457.15.

The salt should be kept in well-stoppered bottles, protected from light, and should contain not less than 99 per cent. of pure salt.—U. S.

Preparation.—No official processes are given in the pharmacopœias. The salt may be prepared by double decomposition between cold or hot solutions of lead nitrate and potassium iodide, containing equal weights of these salts: $Pb(NO_3)_2 + 2KI = PbI_2 + 2KNO_3$. The precipitate of lead iodide is washed with water and dried at a gentle heat. Exactly equivalent quantities of the above salts should be employed, since excess of potassium iodide is a waste and causes loss of precipitate by dissolving a portion of it, and excess of lead nitrate may tend to the formation of a basic iodide. Boudet (1847)

ascertained that lead acetate can not be advantageously used in the preparation of the iodide inasmuch as double iodide of lead and potassium is invariably produced, and remains dissolved in the newly formed potassium acetate. The nitrate does not exert any similar influence; hence nearly the whole theoretical quantity of lead iodide is obtained.

Properties.—Lead iodide, if precipitated in the cold, is a bright-yellow powder, and if obtained from boiling solutions crystallizes in thin, shining, golden-yellow scales. It has the specific gravity 6.1, is inodorous, of a slight metallic taste, and when heated turns brick red or blackish brown, and, if air be excluded, fuses to a red-brown liquid and volatilizes, partly undecomposed, at a strong red heat; on cooling, it gradually acquires again its yellow color. When heated in contact with air, it melts, iodine is given off, and basic lead iodide remains, having an orange-yellow or amber-yellow color. It is permanent in a dry atmosphere, but when exposed to the light while moist is slowly decomposed, lead dioxide and carbonate being formed, besides free iodine. The U. S. Pharmacopœia gives its solubility in cold water (at 25° C.) as 1 in about 1300 parts, and 1 in about 200 parts of boiling water. These solutions are colorless and neutral to test-paper. The salt dissolves more readily in solutions of ammonium chloride, sodium thiosulphate, and of soluble iodides and alkali acetates, and is at least partly converted into double iodides. Alcohol dissolves very little of the salt, and, according to Vogel, boiling ether decomposes it, dissolving iodine and leaving pale-yellow oxyiodide.

Tests.—If 1 Gm. of the salt be triturated with 2 Gm. of ammonium chloride and 2 Cc. of water, a nearly white mixture will result. If this be transferred to a test-tube and heated on a water-bath for a few minutes, a clear and almost colorless solution should be formed (absence of chromate and other insoluble foreign salts). On cooling this solution a solid mass of nearly colorless, fine, silky crystals will be produced, and on adding water or diluted sulphuric acid to this mass, yellow lead iodide will be separated. If 1 Gm. of the salt be boiled for a few minutes with 20 Cc. of water, the mixture then cooled and filtered, the lead removed from the filtrate by hydrogen sulphide, a portion of the second filtrate, after boiling to expel hydrogen sulphide, and carefully neutralizing with ammonia water, should not be colored red by a drop of ferric chloride test-solution (absence of acetate). Another portion of this filtrate, if evaporated to dryness, should leave no residue (absence of soluble foreign salts). If 5 Cc. of water be heated to boiling with 0.1 Gm. of the salt, cooled and filtered into a test-tube, and to the filtrate there be added 5 Cc. of potassium hydroxide test-solution and about 0.2 Gm. of aluminum wire, and a pledget of purified cotton be inserted in the upper part of the tube, and its mouth covered with a piece of moistened red litmus-paper, no blue coloration of the paper should be discernible after heating the tube on a water-bath for 15 minutes (limit of nitrate).—U. S.

Action and Uses.—Lead iodide in the form of the official ointment is a stimulating application to indolent ulcers and sores. If used over a large area or for a long time over a small area, enough of the drug may be absorbed to cause symptoms of chronic poisoning. Internally it has been employed with doubtful utility in scrofulous and other swellings in doses of from ½ to 2 grains (0.03–0.12 Gm.).

PLUMBI NITRAS, *U. S.*—Lead Nitrate.

Plumbum nitricum—Azotate (Nitrate) de plomb, Fr.; *Salpetersaures Bleioxyd, Bleisalpeter*, G.

Formula, $Pb(NO_3)_2$. Molecular weight, 328.49.

It should contain not less than 99.5 per cent. of pure salt, and be kept in well-closed vessels.—U. S.

Preparation.—No official method is given, but it may be obtained by nearly neutralizing warm dilute nitric acid with lead oxide, and crystallizing in a cool place. If prepared from litharge containing copper, the resulting copper nitrate remains at first in the mother-liquor, but will contaminate the last crops of crystals, necessitating washing with water and recrystallization.

Properties.—Lead nitrate crystallizes on slow evaporation in colorless, transparent octahedrons, and in white nearly opaque crystals when hot solutions are cooled. It has the specific gravity 4.4, is not altered by exposure, and when heated decrepitates, fuses,

and gives off oxygen and nitrous vapors, leaving finally lead oxide. It is soluble in 1.85 parts of water at 25° C. (77° F.) and in 0.75 part of boiling water (U. S.). It is likewise soluble, though less freely, in weak alcoholic liquids, but is nearly insoluble in strong alcohol and in nitric acid. The salt is inodorous, possesses a sweetish astringent and somewhat metallic taste, and deflagrates slightly on being triturated with sulphur or thrown upon red-hot charcoal. The aqueous solution has an acid reaction upon blue litmus-paper, and shows the same reactions for lead, and should respond to the same tests for purity as given under PLUMBI ACETAS.

Action and Uses.—Lead nitrate in varying solution is a healing application to sore and cracked nipples, cracked lips, chapped hands, and other excoriations. The solution commonly used contains 10 grains (0.60 Gm.) of the salt to 1 ounce (30 Cc.) of water. This same solution is a useful deodorizing agent to correct the fetor arising from gangrenous sores and offensive discharges from the nose, ears, and vagina. Powdered lead nitrate is said to be an efficient remedy in the treatment of onychia maligna. Its application at first occasions severe pain unless a solution of cocaine is previously applied to the ulcers.

PLUMBI OXIDUM, *U. S., Br.*—Lead Oxide.

Lithargyrum, P. G.; *Plumbum oxydatum. Litharge*, E.; *Protoxide de plomb*, Fr.; *Bleioxyd, Bleiglätte*, G.

Formula, PbO. Molecular weight, 221.23.

It should contain not less than 96 per cent. of pure oxide, and be kept in well-closed vessels.—U. S.

Preparation.—Lead oxide is prepared by combining metallic lead with oxygen derived from the air. If heated to near a white heat, lead begins to volatilize, and in contact with the air burns with a bright-white flame to oxide, which was formerly known as *flowers of lead.* When merely heated to fusion, the metal oxidizes, forming a yellow amorphous powder known as *massicot*, but at a higher temperature the oxide melts and congeals in crystalline scales known as *litharge*, or *semi-vitrified lead oxide.* In this state it is obtained in several processes, such as that known as *cupellation*, in which the lead is oxidized, and the litharge, as it forms, removed by a blast, leaving behind any silver which may have been contained in the lead. An identical product is obtained by passing a current of air over molten lead heated to dull redness and constantly renewing the surface. Nearly all the litharge on the market is now obtained by the cupellation process.

Properties.—Litharge is a more or less crystalline powder which is composed of small scales varying in color between yellowish and pale brick red. When of a distinct yellow tint and glossy surface it has been called *argyritis, yellow* or *silver litharge* (*Silberglätte*, G.), while the red-tinted kind is sometimes known as *crysitis, red* or *gold litharge* (*Goldglätte*, G.). Its density varies between 9.25 and 9.5. It is inodorous and tasteless; in contact with the atmosphere it gradually combines with a little carbonic acid. When heated, it acquires a red-brown color. In the presence of even a small proportion of silica it congeals to a glass-like mass, and in the presence of charcoal it is reduced to metallic lead. It is soluble in dilute nitric acid and in hot acetic acid, the solutions showing with reagents the behavior of lead salts; slightly soluble in water, requiring according to Jorks 12,000 parts for solution, which acquires an alkaline reaction; also soluble in glycerin and in solutions of sugar and other carbohydrates, which on being digested with it acquire a brownish color and a caramel-like odor. In the presence of water it saponifies fats and fatty oils, forming glycerin and lead salts of the fatty acids (lead plaster). If the oxide has absorbed carbon dioxide through careless preservation, it causes trouble in the preparation of lead plaster and lead acetate. English litharge is the best, being free from iron and copper. In the arts litharge is used in the manufacture of flint glass, drying oils, and lead salts for glazing pottery.

Tests.—Lead oxide should be soluble in diluted nitric acid with but little effervescence (limit of carbonate), and without the development of the odor of nitrous acid, leaving not more than a trifling residue (absence of silicate, barium sulphate, etc.). If from the solution in diluted nitric acid the lead be precipitated by sulphuric acid, the filtrate, after the addition of an excess of ammonia-water, should not assume more than a slight bluish tint (limit of copper), nor yield more than traces of a reddish-yellow precipitate (limit of iron). If 5 Gm. of the oxide contained in a small flask be shaken

with 5 Cc. of water, then 20 Cc. of acetic acid added and the mixture boiled for a few minutes, and filtered, the insoluble residue, when well washed and dried, should not weigh more than 0.075 Gm. (absence of more than 1.5 per cent. of insoluble impurities). If to the mixed filtrate and washings obtained in the last test, hydrochloric acid be added in excess, the remainder of the lead removed from the filtrate by hydrogen sulphide, and the liquid filtered, the second filtrate should not yield a residue of more than 0.05 Gm. upon evaporation to dryness (limit of soluble impurities). When strongly heated in a porcelain crucible, the oxide should not lose more than 2 (1, P. G.) per cent. of its weight (limit of carbonate and of moisture).—U. S.

Uses.—Oxide of lead is seldom used alone. A mixture of oxide of lead with sweet oil has been applied to superficial burns, and ordinary white paint, containing litharge, linseed oil, and oil of turpentine, is a popular and excellent remedy for the same affection. Care should be taken not to leave it in contact with the broken skin. Gerhardt has proposed a mixture of oxide of lead and potassa as a caustic for condylomata and warts of the glans penis and vagina. It produces a blackish slough, but does not penetrate deeply.

Other Oxides.—PLUMBI OXIDUM RUBRUM.—*Minium*, P. G.; *Red lead*, E.; *Oxyde rouge de plomb*, Fr.; *Mennige*, G. Pb_3O_4 or $2PbO\text{-}PbO_2$.—On heating massicot to near 450° C. (840° F.) it gradually combines with more oxygen, and is converted into red lead; the conversion of the denser litharge into red lead is attended with greater difficulties. It is a bright orange-red, granular, crystalline powder, which, on being heated, becomes deeper red, purplish, and finally black, and has a density varying between 8.7 and 9.1. It is partly soluble in dilute nitric acid, leaving lead dioxide; at a red heat it is converted into litharge, oxygen being given off; and when heated upon charcoal metallic lead is produced. When mixed with about 20 per cent. of sugar and then treated with dilute nitric acid, it is wholly dissolved. When pure, it contains 90.66 per cent. of lead and 9.34 of oxygen. A variety of red lead less dense than the ordinary kind, and of a bright orange-red color, is used as a pigment under the name of *orange mineral* or *Paris red*.

PLUMBI DIOXIDUM.—*Lead dioxide* (*peroxide*), *Puce oxide of lead*, E.; *Peroxyde* (*Oxyde puce*) *de plomb*, Fr.; *Bleihyperoxid*, G.—This is left behind as an insoluble powder on treating red lead with diluted nitric acid, and is also produced from solution of lead salts by mixing them with an excess of solution of chlorinated lime or chlorinated soda. It is a dark-brown powder, which, on exposure to the light, slowly gives off oxygen, leaving red lead, and by heat is converted into oxygen and litharge. When triturated with one-eighth of its weight of sugar or with its own weight of oxalic acid, it is reduced to oxide or converted into carbonate. Its mixture with sulphur may be ignited by friction—a behavior which renders it useful in the manufacture of matches. Since it readily parts with one-half of its oxygen, it is a valuable reagent for strychnine and some other organic bodies, yielding colored oxidation-products. Its formula is PbO_2, and it contains 86.61 per cent. of lead and 13.39 per cent. of oxygen.

PLUMBUM.—Lead.

Plomb, Fr.; *Blei*, G.

Symbol, Pb. Atomic weight, 205.35. Bivalent or quadrivalent.

Lead has been known from the most remote period. It is found in the United States and many other countries, occasionally as oxide, more frequently as carbonate (*white lead ore*), or in combination with other acids. The most abundant lead ore is *galena*, a lead sulphide, PbS, which is frequently associated with the sulphides of zinc, iron, copper, and silver. The metal is obtained from the galena by roasting it, whereby a portion is oxidized to lead sulphate, while another portion parts with its sulphur, which escapes as sulphur dioxide, the metal being converted into oxide. The newly formed compounds react with the unaltered galena, forming lead, which fuses, and sulphur dioxide, which escapes. A considerable quantity of lead remains in the slag, which is used in a subsequent operation. The extraction of silver is effected by cupellation (see page 235), and the lead oxide is then reduced to the metallic state by heating it with charcoal.

Lead has a bluish-gray color and a bright metallic lustre. It is a soft metal, and when cooled slowly leaves a mark on being drawn over paper. Its specific gravity is 11.4; it is very malleable and ductile, but less tenacious than most other common metals; fuses at 325° C. (617° F.) and volatilizes at a white heat. On congealing, it expands slightly, but afterward contracts considerably, and under some circumstances it may be obtained crystallized in regular octahedrons. When exposed to a moist

atmosphere, it is superficially oxidized and becomes covered with a grayish layer. In contact with water and air or in the presence of a minute quantity of ammonia or of nitric acid, the metal is corroded and small quantities of it are held in solution. Sulphates prevent the lead from being dissolved, or, if dissolved, precipitate an insoluble sulphate. The effect of lead pipes on drinking-water is stated under AQUA (which see).

In addition to the three oxides described elsewhere, the existence of a suboxide, Pb_2O, has been assumed, but is doubted by many chemists. *Lead sesquioxide*, $Pb_2O_3 = PbO.PbO_2$, has been obtained as a yellow precipitate by adding chlorinated soda to an alkaline solution of lead, and more recently (1878) by H. Debray as a greenish-brown powder by heating lead peroxide to 350° C. (662° F.).

There are two series of *lead salts*, in one of which lead is contained in the acidulous radical, while in the other it constitutes the base. The former, called *plumbites* and *plumbates*, analogous to zincates and stannates, are formed when strong alkalies act on lead oxide and lead dioxide, respectively, the potassium compounds being K_2PbO_2 and K_2PbO_3. The alkali plumbates are colorless, decomposed by much water, and yield plumbates of the metals by acting upon metallic salts. The *plumbic salts* are white or colorless, unless colored by the acid; mostly insoluble in water, and then usually soluble in dilute nitric acid. The salts, which are soluble in water, have a sweet and metallic taste and an acid reaction to litmus, and their solutions yield white precipitates with carbonates, sulphates, phosphates, and chlorides, the last of which is slightly soluble in water, but less soluble in hydrochloric acid, while the precipitated lead sulphate is insoluble in water and dilute sulphuric and hydrochloric acids. Alkalies produce white precipitates of plumbic hydroxide, which is insoluble in ammonia, but soluble in potassa and soda. Potassium ferrocyanide yields a white precipitate. The precipitates by potassium chromate and potassium iodide are characterized by a bright-yellow color; the latter crystallizes from hot solutions in golden-colored scales. Hydrogen sulphide precipitates black lead sulphide, which is insoluble in dilute acids and in ammonium sulphide. Iron and zinc separate from the solutions of lead salts the lead in the metallic state, and by heating the salts with sodium carbonate upon charcoal before the blow-pipe, metallic globules of lead and a reddish-yellow incrustation of lead oxide are obtained.

Action and Uses.—Lead produces, when taken internally in poisonous doses in any of its soluble forms, a widespread gastro-enteritis and death from these intense inflammatory changes and the depressant effect exerted upon the central nervous system. The vomitus is white, owing to the formation of chloride of lead, and the stools are black from the formation of sulphide of lead. Vomiting is often a symptom of such poisoning, and constipation may be present instead of purging, owing to the astringent effect of the drug. The antidote to the soluble salts of lead is any soluble sulphate, such as Epsom or Glauber's salt, which also, if given freely, purge the patient of the poison. Chronic lead-poisoning is a very common condition and occurs in all walks of life. The poison finds its way into the body in a host of ways. In painters, as a result of the absorption of the drug while working with lead paint; in artisans who work in lead, in persons who eat cakes colored by chrome yellow, in others who eat preserved fruits kept in jars glazed with lead. A characteristic symptom is a blue line on the gums in those who are not careful in the cleansing of the mouth after meals. This is due to the formation of the sulphide of lead in the capillaries of the gums. Another very marked characteristic of chronic lead-poisoning is bilateral wrist-drop owing to the paralysis of the extensor muscles of the forearm. Still another is painters' colic, or *colica pictonum*, in which an agonizing, griping pain is felt above the navel. Lead-poisoning also causes a universal neuritis in some cases, producing symptoms like those of locomotor ataxia. More rarely chronic joint-changes take place like those of gout or rheumatoid arthritis, the so-called "plumbic gout." Still more rarely convulsions ensue as the result of saturnine encephalopathy. Often, however, these convulsions are really due to uræmia produced by the effect of the poison on the kidneys. Chronic lead-poisoning is to be treated by avoiding further exposure, by the use of potassium iodide to aid in the elimination of the drug, and by the use of electricity and strychnine to restore lost nerve power. Chronic lead-poisoning is usually due to the ingestion of the insoluble rather than the salts of lead.

UNOFFICIAL COMPOUNDS OF LEAD.

Plumbi Chloridum.—*Lead chloride*, E. ; *Chlorure de plomb*, Fr. ; *Bleichlorid, Chlorblei*, G. $PbCl_2$.—Obtained by precipitating lead acetate or nitrate solution with hydrochloric acid, washing and drying the precipitate. Colorless crystalline powder, or crystals, soluble in 140 parts of cold and 30 parts of boiling water. Basic lead chloride is sold as a pigment by the name of *Mineral-, Turner's, Veronese, Paris*, or *patent yellow*.

Plumbi Chromas.—*Lead chromate*, E. ; *Bleichromat, Chromsaures Blei*, G. $PbCrO_4$.—Obtained by interaction between lead acetate or nitrate and potassium chromate or dichromate. A heavy, beautiful yellow powder, insoluble in water and dilute acetic acid, easily soluble in caustic alkalies. It is sold in the market as a pigment usually under the name of *Chrome yellow, Paris yellow*, or *lemon-chrome*. *Basic lead chromate*, $PbCrO_4.PbO$, is obtained by treating chrome yellow with very dilute caustic soda or by boiling it with lime-water. It is a heavy, bright-red powder known as *Chrome red, Chrome orange*, or *American vermilion*. A mixture of chrome yellow and Prussian blue constitutes *Chrome green*.

Plumbi Tannas.—*Lead tannate*, E. ; *Bleitannat, Gerbsaures Blei*, G.—Obtained by dropping a solution of tannin into a solution of lead acetate, washing and drying the precipitate. It is at first nearly white, but gradually turns brown.

Action and Uses.—The chloride and tannate of lead have been used externally in ointment as a soothing application to ulcers and morbid growths. Lead chromate or chrome yellow has been responsible for many cases of chronic lead-poisoning when employed to give a rich yellow color to pastry.

PODOPHYLLUM, *U. S.*—Podophyllum ; May-apple.

Podophylli rhizoma, Br. ; *Mandrake-root, Vegetable Calomel*, E. ; *Fussblattwurzel*, G. ; *Rhizoma de Podophyllum*, Fr. ; *Podifillo*, It. ; *Podofilo*, Sp.

The dried rhizome of *Podophyllum peltatum* L. (*P. callicarpum* Raf.)—Fam. *Berberidaceæ*.

American mandrake is official in most pharmacopœias. The Belgian requires that it yield from 3 to 5 per cent. of podophyllin.

Origin.—Podophyllum, commonly known as *Umbrella-plant* or *Duck's foot*, grows abundantly throughout almost the whole of eastern and central North America, preferring a rather low, heavy, and clayey soil and open or partially open exposures. It is a perennial herb, growing from very long and much branched rhizomes, so as to form very large beds. It is a plant of very striking appearance. The aërial portion from the younger rhizomes consists of a slender stem about a foot high, terminating in a centrally peltate, smooth and shining leaf about 6 to 12 inches in diameter, nearly circular in outline, the margin coarsely and irregularly lobed and somewhat drooping, thus giving to the plant one of its popular names, Umbrella Plant. The stems from the older parts of the rhizome terminate in a single, recurved, beautifully waxy, white flower, about 2 inches broad, and 2 leaves, their stout petioles rising obliquely on the two sides, the blades somewhat more than semicircular, otherwise similar to those previously described, though a little larger. The fruit is a bright-yellow, soft and fleshy, very many seeded berry, which is somewhat sweet and edible. A few cases of poisoning, 2 of them fatal, have been reported from eating this fruit. Although the cases are thoroughly authenti-

FIG. 322.

Rhizome of *Podophyllum peltatum* L.

cated, they are not easily understood, since the fruit is ordinarily eaten freely without unpleasant results, under the names *Wild* or *Ground lemon, Indian, Hog*, or *Devil's apple*. In the rich alluvial lands of our central States, the rhizome is turned up by

the plough in the greatest abundance and is collected and marketed in great quantities and at small cost.

Description.—Of horizontal growth and indefinite length, occurring in irregular pieces; cylindraceous, lightly flattened from above, consisting of joints about 5 to 10 Cm. (2–4 In.) long, the internodes 2 to 8 Mm. ($\frac{1}{12}$–$\frac{1}{3}$ In.) thick, the nodes about twice as broad; yellowish brown to dark brown, the darker pieces usually longitudinally wrinkled, the lighter ones nearly smooth, the nodes marked above by broad cup-shaped scars and underneath by whitish, short stumps of the brittle roots; fracture short and sharp, whitish to pale brown, resinous in the best drug, marked by a loose circle of very short yellow wood-wedges surrounding a large pith; nearly inodorous; taste sweetish and bitter, becoming acrid.

The powder contains simple and compound starch-grains, the former from very minute up to 6 or 7 mikrons wide, the hilum from centric to very excentric, the rings obscure, and calcium oxalate crystals in rosettes of very irregular size, mostly 35 to 40 mikrons wide.

The thinner, dark-colored, much-wrinkled portions of mandrake rhizome are deficient in active constituent.

Constituents.—With a large amount of starch, small amounts of gum and fixed oil, and a very small amount of gallic acid, podophyllum yields $3\frac{1}{2}$ to 5 per cent. of a brownish-yellow resinous substance, soluble in alcohol but not in water, in which the activity resides. This resin is commonly denominated "Podophyllin" and is a mixed substance, for the composition and properties of which see RESINA PODOPHYLLI.

Pharmaceutical Preparations.—FLUIDEXTRACT OF PODOPHYLLUM, PILLS OF PODOPHYLLUM, BELLADONNA, AND CAPSICUM, RESIN OF PODOPHYLLUM, U. S. P.

Action and Uses.—Podophyllum is the slowest-acting official purge in the Pharmacopœia, requiring from 10 to 24 hours to produce its effect. In small doses it is a mild laxative, and in large amounts it produces copious, watery stools often attended with severe griping.

In overdose it causes vomiting, hypercatharsis, gastro-enteritis with bloody stools, general depression, and sometimes death. The experiments of Rutherford indicate that the drug distinctly excites the flow of bile, which renders it a useful cholagogue.

While it may be used in any case of constipation, it is of particular value in the constipation resulting from hepatic torpor and portal congestion, and is perhaps preferable to all other drugs except calomel. In the summer diarrhœas of children, when the passages consist almost entirely of water and have a peculiar mousy odor, the resin of podophyllum, in doses of from $\frac{1}{60}$ to $\frac{1}{50}$ grain (0.0010–0.0013 Gm.), repeated every few hours, will often cure when all other remedies have failed.

The Resina Podophylli, improperly called podophyllin, is the preparation usually employed when podophyllum is indicated. Its dose as a laxative is from $\frac{1}{20}$ to $\frac{1}{1}$ grain (0.003–0.006 Gm.); as a purge, from $\frac{1}{8}$ to $\frac{1}{2}$ grain (0.008–0.032 Gm.). The drug in substance is given in from 5- to 10-grain (0.30–0.60 Gm.) doses as a laxative, 10 to 20 grains (0.60–1.30 Gm.) as a purge. The dose of the extract is about one-half that of the drug.

Other Species.—5 species of *Podophyllum* are recognized. Only 1 other than the above has been investigated pharmacologically, namely, *P. Emodi* Wall., of the East Indies, especially of the Himalayan region. This is a somewhat larger plant and produces a larger, orange-red or scarlet berry. The rhizome yields 2 or 3 times as much resin as the official article, but this resin has a different composition and is considered inferior.

POLYGONACEÆ.—The Smart-weed Family.

A family of 30 genera and nearly 700 species, of world-wide distribution and most diverse habits and properties. The economic importance of the family is considerable. Under the name *Buckwheat*, the seeds of *Fagopyrum Fagopyrum* (L.) Karsten (*Polygonum F.*—L.; *F. esculentum* Mœnch), ordinary *Buckwheat* or *Indian wheat*, *Crap*, *Heath*, or *Saracen's corn*, *Buchweitzen* (G.), *Sanasin* or *Blé noir* (Fr.), of *F. cymosum* Meissn., the *Chinese perennial buckwheat*, and of *F Tartaricum* (L.) Gærtn. (*Polygonum F.*—L.), the *Tartary* or *Rough buckwheat*, constitute an important source of flour. The fleshy fruits of several species of *Coccoloba*, of tropical America, are edible, as are the petioles of several species of *Rheum*, the well-known *Pie-plant*, and the leaves of *Rumex crispus* L. and of other species of *Rumex*. From a

medicinal point of view, the family is of considerable importance, yielding RHEUM and RUMEX, elsewhere considered. The prevailing property of the family is its astringency.

The root of *Rumex hymenosepalus* Torr. (*Cañaigre*) is an important tanning agent. This is a low-growing species, forming clumps or small beds in sandy soil through the southwestern United States and Mexico. The petioles are acid, and are sometimes used as a substitute for pie-plant. The fusiform, turnip-like roots are mostly about 15 Cm. (6 In.) long and a third as thick, when fresh, losing a third to a half of this thickness on drying. If dried entire, they are of a dark red-brown color, bearing a number of short transverse cracks, through which a light-brown inner layer can be seen. Internally they are of a bright reddish brown, with narrow wood-bundles and broad medullary rays. If first peeled, they dry with a number of sharp ridges separated by broad grooves. They contain about 25 per cent. of rheotannic acid, 18 of starch, about 1 of yellow resin, 20 of coloring-matter and sugar, and a trace of emodin.

Coccoloba Unifera L., the *Sea-* or *Tree-grape* or *Lobe-berry* of the West Indies, is similarly astringent, and an extract of its wood is somewhat known as *West Indian* or *Curaçoa Kino.*

The roots of many species of the large West American genus *Eriogonum* are highly astringent and furnish intestinal astringents to the aborigines and settlers.

The roots of many species of *Polygonum* (see *Bistorta*, sub GERANIUM) are similarly astringent. This genus is most noted, however, for the sharp acridity of the juices of a number of species, called on this account *Smart-weeds.* In medicine, the names *Polygonum*, *Water pepper*, and *Smart-weed* are commonly understood as applying to the fresh herbage of *P. hydropiper* L. It is a smooth annual, with weak stems, from 1 to 3 feet high, growing in and near water, in mud. The nodes are swollen and surrounded by cylindrical, shortly fringed sheaths. The leaves are lanceolate, more or less acuminate, ciliate, and pellucid-punctate, like the greenish, mostly 4-lobed calyx. The flowers are in panicled, drooping, mostly interrupted racemes and are greenish white, and usually 4-merons. The active principle is not understood, but has been called *polygonic acid.* It is destroyed by heating or drying. The plant contains 3 or 4 per cent. of tannin.

About 40 species of *Polygonum* are recorded as being medicinally employed. A number of species yield blue or yellow dyestuffs, and *P. tinctorium* Ait. is a source of Indigo in the Orient.

POPULUS CANDICANS.

Balm of Gilead Buds.

The buds of *Populus candicans* Ait. (*P. balsamifera candicans* A. Gray), gathered in late winter or early spring.

Origin.—The Balm of Gilead tree reaches a height of nearly 100 feet and a trunk diameter of 6 feet or more, abounding through eastern and central Canada and extending into the northern United States. The winter buds are very large and open in earliest spring, hence are very subject to injury from inclement weather and are specially protected by tough cartilaginous scales, heavily coated with oleoresin, the latter giving them their aromatic and medicinal properties.

FIG. 323.

Populus candicans buds (⅔ Nat.).

Description.—Solitary or 2 or 3 united by the bases; from 2 to 3.5 Cm. ($\frac{3}{5}$ to $1\frac{2}{5}$ In.) long by 6 to 9 Mm. ($\frac{1}{4}$ to $\frac{1}{3}$ In.) broad, ovate, long and sharply pointed, more or less flattened; surface exhibiting several large scales, dark brown, shining from the presence of a thick coat of soft and sticky resin; consisting of a series of thick, imbricated scales and enclosing one or more rudimentary catkins of rudimentary flowers, each subtended by a small fringed scale, and the whole held together by soft, sticky, yellowish-brown resin similar to that upon the surface; odor and taste pleasantly balsamic, the latter afterward a little acrid.

Constituents.—No examination of the constituents appears to have been made. The presence of volatile oil and resin are obvious. Black Poplar Buds contain an oil having the odor of chamomile, but that of the species under consideration is evidently quite distinct.

Action and Uses.—Populus candicans may be employed, like the other terebinthinates, as a stimulating expectorant, and in the form of ointment as an application to sluggish ulcers and sores.

POTASSA SULPHURATA, *Br.*—Sulphurated Potash.

Kalium sulfuratum, P. G.; *Hepar sulphuris.—Sulphurated potassa. Sulphuret of potassium, Liver of sulphur*, E.; *Sulfure de potasse, Foie de soufre*, Fr.; *Schwefelleber*, G.

A mixture of salts of potassium, of which the chief are potassium sulphides.

Origin.—The name "liver of sulphur" was introduced by Basilius Valentinus in the fifteenth century, but the process of melting together sulphur with an alkali was known already to Albertus Magnus in the thirteenth century, and the solubility of sulphur in alkalies to Geber in the eighth century. Spielmann (1766) recommended the preparation of liver of sulphur from 2 parts of potassium carbonate and 1 part of sulphur, in which proportions the ingredients are still employed.

Preparation.—The Br. P. directs sulphurated potash to be made by mixing potassium carbonate, previously dried, 10 ounces, and sulphur, 5 ounces, in a warm mortar, introducing the mixture into a crucible, which is heated, at first gradually, until effervescence has ceased, and finally to dull redness, so as to produce perfect fusion. The liquid contents of the crucible are poured out on a clean flagstone and quickly covered with an inverted porcelain basin, in order to prevent free access of air while solidifying. The solid product should, when cool, be broken into fragments and immediately enclosed in a green glass bottle furnished with an air-tight stopper.

On fusing sulphur with potassium carbonate the latter is decomposed, with the evolution of carbon dioxide, the sulphur uniting with the potassium to form a potassium polysulphide, a portion of which is oxidized by the oxygen of the carbonate, in excess over that contained in the carbon dioxide, to form potassium sulphate or thiosulphate; $4K_2CO_3 + 5S_2$ yields $K_2SO_4 + 3K_2S_3 + 4CO_2$, and $3K_2CO_3 + 4S_2$ yields $K_2S_2O_3 + 2K_2S_3 + 3CO_2$. But the degree of heat is likewise of importance, since at a high temperature the potassium thiosulphate is decomposed into pentasulphide and sulphate; $4K_2S_2O_3$ yields $K_2S_5 + 3K_2SO_4$. It is evident from this that products of very different composition are obtained by varying the proportion of the material; or, if this be used in the same relative proportions, by the injudicious application of heat, by which a part of the sulphur may be sublimed.

Properties and Tests.—Sulphurated potash, when recently made or well preserved in closed vessels, is in irregular fragments, breaking with a shallow conchoidal fracture and having a liver-brown color, which in contact with moisture changes to greenish yellow or brownish yellow. It has a slight odor of hydrogen sulphide, a bitter and acridly alkaline sulphurous taste, and an alkaline reaction to test-paper. It is partly deliquescent on exposure, and yields with water a brownish-yellow solution which has a strong odor of hydrogen sulphide, and evolves the latter freely on the addition of hydrochloric acid, sulphur being at the same time deposited. After boiling the hydrochloric acid solution until the hydrogen sulphide has been expelled, the liquid, freed from sulphur by filtration, will yield an abundant white crystalline precipitate with solution of tartaric acid (P. G.). About 50 per cent. of the sulphurated potash should be soluble in 90 per cent. alcohol (Br.).

When intended for internal use, the compound should be perfectly soluble in 2 parts of water. For external use an impurer article, *Kalium sulfuratum ad balneum*, is made like the above, with the exception that impure potassium carbonate (pearlash) is substituted for the purified.

If not protected from contact with air, sulphurated potash becomes green, and afterward gray, being partly converted into carbonate through the carbon dioxide of the air, and partly oxidized to thiosulphate, sulphite, and sulphate, sulphur being at the same time liberated.

Potassii Sulphidum.—*Potassium monosulphide.* K_2S.—Hydrogen sulphide gas is conducted into a solution of potassium hydroxide as long as it is absorbed, and an equal bulk of a like solution is added. The colorless liquid has a bitter taste and a strongly alkaline reaction, and on evaporation *in vacuo* yields colorless deliquescent quadrangular prisms, containing $5H_2O$, which are somewhat soluble in alcohol. The reactions taking place are: $KOH + H_2S = KSH + H_2O$ and $KSH + KOH = K_2S + H_2O$.

Besides the monosulphide and trisulphide, there are three others, namely, K_2S_2, K_2S_4, and K_2S_5. All except the monosulphide are yellow, and are oxidized when in contact with the air, forming potassium thiosulphate. They may be obtained by the action of sulphur on a solution of potassium hydrosulphide.

Potassii Sulphocarbonas.—*Potassium sulphocarbonate* or *thiocarbonate*, K_2CS_3.—On agitating a solution of potassium monosulphide with carbon disulphide the liquid acquires a yellow or red-brown color, according to its concentration and purity, and on careful evaporation at 30° C. (86° F.) yields orange-yellow deliquescent crystals of the hydrated salt, or a crystalline precipitate of the same salt on mixing the brown liquid with alcohol. It has a cooling, pungent, and somewhat sulphurous taste, and is sparingly soluble in alcohol. A solution containing also potassium carbonate, but sufficiently pure for destroying the *phylloxera* and other insects, is made by agitating potassium hydroxide solution with carbon disulphide as long as the latter is dissolved; and if alcohol be present, *potassium xanthogenate*, $K(C_2H_5)CS_2O$, is also formed. Both salts are slowly decomposed in the soil, with the liberation of carbon disulphide. Such a solution has been employed in Europe for the destruction of the phylloxera insect which infests grapevines.

Potassium Dithiocarbonate. K_2COS_2.—This is formed, as just stated, when carbon disulphide acts on hot caustic potash. It forms a reddish deliquescent salt, soluble in water and alcohol, and is employed in skin diseases as a 5 per cent. solution or ointment.

Action and Uses.—The disagreeable odor and taste of sulphurated potassa, and especially the doubt as to its merit in the host of diseases for which it has been recommended, account for its rare employment in internal medicine. Some of the diseases which it was thought to benefit were membranous croup, chronic rheumatism, gout, asthma, pulmonary tuberculosis, whooping-cough, and acute poisoning by lead, arsenic, and mercury. Externally, in lotions, baths, and ointments, it is employed with good effect in acne, psoriasis, scabies, and other skin eruptions. The strength of the lotion should be about 15 grains (1 Gm.) of the drug to the ounce (30 Cc.) of water, and of the bath, 15 grains (1 Gm.) to the gallon (4 L.). An ounce of ointment should contain about 30 grains of potassa sulphurata. If given internally, the dose is from 3 to 10 grains (0.20–0.60 Gm.).

POTASSII ACETAS, *U. S., Br.*—Potassium Acetate.

Kalium, s. Kali aceticum, Terra foliata tartari. Acetate of potash, E.; *Acétate de potasse*, Fr.; *Kaliumacetat, Essigsaures Kali*, G.

Formula, $KC_2H_3O_2$. Molecular weight, 97.44.

Potassium acetate should be kept in well-stoppered bottles and contain not less than 98 per cent. of pure salt.—U. S.

Preparation.—No method of preparation is given in the pharmacopœias. It may be obtained by almost neutralizing a solution of acetic acid with pure potassium carbonate or bicarbonate, filtering if necessary, and evaporating, first on a water-bath, then on a sand-bath, to complete dryness. Toward the end of the evaporation the mass must be stirred to prevent spurting. Acetic acid should be slightly in excess, since any excess of alkali would give rise to discoloration, which would also result if the temperature of the sand-bath were too high. With care, the powdery acetate may be fused without decomposition and obtained in masses on cooling. The salt should be bottled at once and the corks paraffined.

On adding potassium carbonate or bicarbonate to acetic acid effervescence of carbon dioxide takes place, and water and potassium acetate are formed; $K_2CO_3 + 2HC_2H_3O_2$ yields $2KC_2H_3O_2 + H_2O + CO_2$, and $KHCO_3 + HC_2H_3O_2 = KC_2H_3O_2 + H_2O + CO_2$.

Potassium bicarbonate is preferable in being nearly free from impurities and yielding at once a salt perfectly soluble in water. Potassium carbonate is less pure, but usually yields a clear solution with acetic acid, which, on being evaporated to dryness and again dissolved in water containing a little acetic acid, leaves some floccules of silica behind, from which it may be filtered and afterward again evaporated.

Potassium acetate may also be prepared from lead acetate by precipitating its solution with a slight excess of potassium carbonate, filtering, acidulating the filtrate with acetic acid, testing with hydrogen sulphide to insure its complete freedom from lead, and evaporating.

Properties.—Potassium acetate is a white salt forming a crystalline soft mass or a dry granular powder, or more frequently it is seen as a satiny, foliaceous, crystalline mass which melts to an oily liquid at about 292° C. (557.6° F.), and at a higher temperature evolves acetic acid, acetone, empyreumatic, and inflammable products (an alliaceous odor would indicate the presence of arsenic), and finally leaves a white residue

of potassium carbonate, which should be completely soluble in water. The salt is nearly inodorous, is free from acetous odor, has a warm and somewhat pungently saline taste, and is very deliquescent in the air. It dissolves at 25° C. (77° F.) in 0.40 part of water and in 2 parts of alcohol. The aqueous solution, saturated while boiling, contains 1 part of the salt to 0.125 part of water, and boils at 169° C. (336° F.) (Berzelius). Cold absolute alcohol dissolves one-third, and at the boiling temperature one-half, its weight of the salt. The alcoholic solution on the addition of ether gives a crystalline precipitate of the salt, and on passing carbon dioxide through it potassium carbonate is separated and acetic ether produced. The aqueous solution has a faintly alkaline reaction to litmus, but no effect on phenolphthalein, and disengages acetous vapors on the addition of sulphuric acid. The addition of sodium bitartrate test-solution to the concentrated aqueous solution causes a white precipitate of potassium bitartrate. With ferric chloride a dark-red color (ferric acetate) is produced, and, on boiling, a brown-red precipitate (ferric hydroxide). On triturating the salt with iodine it aquires an indigo-blue color, changing to brown on the addition of water.

Tests.—A solution of potassium acetate in distilled water slightly acidulated with acetic acid should not give a precipitate or a turbidity on the addition of an equal volume of hydrogen sulphide solution, when kept corked and warm for at least half an hour, either before or after making slightly alkaline with ammonia-water (absence of heavy metals). 5 Cc. of the aqueous solution (1 in 10) of the salt should not respond to the modified Gutzeit test for arsenic (see under ARSENI TRIOXIDUM).

If 1 Gm. of dry potassium acetate be thoroughly ignited, at red heat, and converted, the residue extracted with hot water and filtered, the filtrate should require for complete neutralization not less than 20.1 Cc. of half-normal sulphuric acid, methyl-orange being used as indicator.—U. S. Each Cc. of the acid solution represents 0.04872 Gm. of the acetate after it has been converted to carbonate, and 20.1 Cc. would show 97.93 per cent., instead of 98 as given above. This test is intended to prove the absence of sodium acetate and of more than 2 per cent. of moisture. The latter is more readily estimated by drying the salt at 120° C. (248° F.); considering the hygroscopic nature of the salt, 3 or 4 per cent. of moisture would seem to be admissible. The presence of notable quantities of sodium acetate is best determined by the intense yellow color imparted by the salt to a non-luminous flame. 4.9 Gm. of dry potassium acetate, evaporated to dryness with an excess of hydrochloric acid, leave a residue of KCl weighing 3.72 Gm., or, allowing for 2 per cent. of moisture, 3.645 Gm. The same weight of exsiccated sodium acetate leaves only 3.49 Gm., and of the crystallized sodium salt 2.104 Gm., NaCl. The U. S. P. (1900) has dropped the test for limit of chloride, while the Br. demands the absence of more than a trace.

Pharmaceutical Uses.—Potassium acetate, being unfit for dispensing in the dry state, is always prescribed in solution. For convenience in dispensing, the German Pharmacopœia recognizes—

Liquor Kalii Acetici, which contains one-third of its weight of the dry salt, and is prepared by neutralizing 100 parts of acetic acid, specific gravity 1.041, with 48 or 50 parts of potassium bicarbonate, expelling the carbon dioxide by heat, and diluting with sufficient water to obtain 147 parts. Its specific gravity is 1.176–1.180.

Action and Uses.—Potassium acetate, like the other alkaline salts of vegetable acids, is decomposed in the alimentary canal and absorbed into the blood as a carbonate, thereby increasing the normal alkalinity of that fluid and decreasing the normal acidity of the urine, which may be rendered distinctly alkaline if a sufficient quantity of the drug be given. The salt also increases the quantity of urine excreted. Because of these properties potassium acetate is employed in the alkaline treatment of acute rheumatism, and is held in esteem by some practitioners in the treatment of the so-called uric-acid diathesis and uric-acid gravel. It probably does good in these conditions by the thorough flushing the kidneys receive through the increase in the urinary flow, and by reducing the hyperacidity of the urine it relieves the irritability of the bladder. In the quantities that can be safely ingested the drug has no effect whatever toward the solution of calculi already formed. As a diuretic it may be given with advantage in dropsy due to acute desquamative nephritis and in other forms of renal and cardiac dropsy. It is a useful diaphoretic in acute febrile affections, especially in children. In doses of from ½ to 1 ounce (16–30 Gm.) it possesses purgative properties, for which it has been employed in catarrhal jaundice and in the jaundice of chronic malaria and hepatic torpor. At

one time it was supposed to purify the blood by aiding the oxidation of effete material. In psoriasis, eczema, and other cutaneous eruptions it may be given with benefit. The dose of potassium acetate as a diuretic is from 10 to 30 grains (0.60–2 Gm.) in a large quantity of water; as a purge, from ½ to 1 ounce (16–30 Gm.).

POTASSII BICARBONAS, *U. S.*, *Br.*—Potassium Bicarbonate.

Kalium bicarbonicum, P. G.; *Kali carbonicum acidulum.—Bicarbonate of potash, Potassium hydrogen carbonate*, E.; *Bicarbonate de potasse*, Fr.; *Kaliumbicarbonat, Doppeltkohlensaures Kali*, G.

Formula, $KHCO_3$. Molecular weight, 99.41.

The salt should be kept in well-stoppered bottles and contain not less than 99 per cent. of pure bicarbonate.—U. S.

Preparation.—This salt was first prepared by Cartheuser (1757) from potash and ammonium carbonate. Cavendish originated the process which is still used, acting with carbon dioxide upon a solution of the carbonate. The salt is best prepared on a large scale, and the essential feature of any method is the conversion of the very soluble normal carbonate, K_2CO_3, into the less soluble acid carbonate by the action of carbon dioxide; thus, $K_2CO_3 + CO_2 + H_2O = 2KHCO_3$. The completion of the change to bicarbonate is determined by adding to a portion of the solution mercuric chloride solution, which should give no red precipitate, or magnesium sulphate solution, which should give no precipitate (carbonate would give a red precipitate in the first case and a white one in the second). After 24 hours' standing in a cool place the crystals are filtered and washed with ice water and dried at 25° C. (77° F.) in an atmosphere of carbon dioxide. Potassium bicarbonate is manufactured to some extent from potassium chloride by the Solvay process described under SODII CARBONAS, but trimethylamine is used instead of ammonia, since the chloride of the former produced in the process is more soluble than the ammonium chloride, and thus permits of a greater concentration of the solution and larger yield of the potassium bicarbonate. The reaction is: $KCl + N(CH_3)_3 + H_2O + CO_2 = KHCO_3 + N(CH_3)_3HCl$. Another method of manufacture consists in saturating with carbon dioxide the caustic potash solution obtained by electrolyzing potassium chloride (see under POTASSIUM HYDROXIDE).

Properties.—Potassium bicarbonate crystallizes in transparent, colorless, monoclinic prisms, which are permanent in the air, inodorous, and have a saline and slightly alkaline, but not a caustic taste. At 100° C. (212° F.) it begins to lose CO_2 slowly, but the conversion to carbonate is not complete until 350° C. (662° F.) is reached, whereby 30.97 per cent. of the weight is lost. The salt is very sparingly soluble in alcohol, and at 25° C. (77° F.) dissolves in 3 (U. S.) (4, Br., P. G.) parts of water, or in 1.9 parts at 50° C. (122° F.) (U. S.). According to Poggiale, 100 parts of water dissolve at 10° C. (50° F.) 23.23 parts, at 20° C. (68° F.) 26.91 parts, and at 60° C. (140° F.) 41.35 parts of the salt; the solution of the pure salt has at first a neutral reaction to litmus-paper and phenolphthalein, but soon becomes feebly alkaline by partial conversion of the salt into carbonate, effervesces briskly on the addition of acids, yields with an excess of tartaric acid a white crystalline precipitate of potassium bitartrate, and loses carbon dioxide slowly when evaporated *in vacuo*, and rapidly when heated to the boiling-point, leaving carbonate in solution. 5 Gm. of the salt exposed to a low red heat leave 3.45 Gm. of a white residue consisting of potassium carbonate.

14 parts of citric and 15 parts of tartaric acid are neutralized by 20 parts of potassium bicarbonate. A less pure potassium bicarbonate in a pulverulent state is met with in commerce under the name of *sal aëratus*, but much sold as such is sodium bicarbonate.

Tests.—The presence of potassium carbonate causes the bicarbonate to become moist on exposure, and its solution in cold water to yield a white precipitate with magnesium sulphate and a yellow or brick-red one with corrosive sublimate; the latter reagent produces a white precipitate with pure potassium bicarbonate. If to 1 Gm. of the salt, dissolved in 20 Cc. of water at or below 15° C. (59° F.) without agitation, 0.2 Cc. of normal hydrochloric acid and 2 drops of phenolphthalein test-solution be added, a red tint should not appear immediately (limit of carbonate). The aqueous solution of the salt, slightly acidulated with hydrochloric acid, should not give a precipitate or coloration when treated with hydrogen sulphide solution as described under POTASSIUM

Carbonate (absence of heavy metals). To neutralize 1 Gm. of potassium bicarbonate should require not less than 9.96 Cc. (10 Cc., Br. P. and P. G.) of normal sulphuric acid (corresponding to 99 per cent. of the pure salt), methyl-orange being used as indicator.—U. S. Each Cc. of normal acid is equivalent to 0.09941 Gm. of the salt. When heated to redness, the residue should be 69 per cent. of the weight of the salt (Br. P. and P. G.), which should not undergo temporary charring (P. G.). The U. S. P. of 1900 has omitted tests for limit of iron and chloride, while the Br. P. and P. G. give tests for these and sulphate, and in addition the Br. P. has tests for calcium, magnesium, sulphides, and nitrates. The latter seems to be a case of excessive refinement.

Metallic salts, if present as impurities, remain behind on dissolving the salt in water, or are indicated by producing a precipitate on the addition of hydrogen sulphide. Sodium salts present as impurities will impart an intense yellow color to a non-luminous flame. The complete solubility of the salt in 4 parts of cold water excludes notable quantities of sodium bicarbonate. Potassium bicarbonate represents 47 per cent. of K_2O, 44 per cent. of CO_2, and 9 per cent. of H_2O.

Action and Uses.—Potassium bicarbonate acts like the acetate and citrate in increasing the excretion of urine and reducing its acidity. Because of this action it relieves the pain and irritability of the bladder caused by a too acid urine. Its value in the gouty and uric-acid diathesis depends more upon the increased flow of urine produced by the drug than upon any specific action attributed to it in preventing the formation and deposition of uric acid or urates in the tissues. As an antacid it is beneficial in relieving the pain and eructations due to hyperacidity of the stomach contents, but it has been largely replaced by sodium bicarbonate in this condition.

Potassium bicarbonate frequently relieves jaundice, especially that due to a catarrhal condition of the mucous membrane of the bile-ducts and duodenum. Added to expectorant mixtures, it increases the bronchial secretion and renders it more fluid.

From potassium bicarbonate are made the liquor potassii citratis and neutral mixture, the latter by adding enough potassium bicarbonate to lemon-juice to neutralize it. The dose of potassium bicarbonate is from 5 to 40 grains (0.3–2.6 Gm.), but as much as 2 drachms (4 Gm.) may be given, well diluted with water.

POTASSII BITARTRAS, *U. S.*—Potassium Bitartrate.

Potassii tartras acidus, Br.; *Tartarus depuratus*, P. G.; *Cremor tartari, Kalium-bitartaricum.—Acid tartrate of potash, Cream of tartar*, E.; *Bitartrate de potasse, Crème de tartre, Pierre de vin*, Fr.; *Weinstein*, G.

Formula, $KHC_4H_4O_6$. Molecular weight, 186.78.

Potassium bitartrate should contain at least 99 per cent. of the pure salt.—U. S.

Origin.—Acid potassium tartrate is contained in many acidulous fruits, but is collected altogether from the juice of the grape, in which it becomes insoluble after fermentation, and is deposited in the casks in crystalline crusts. These form the *crude tartar* or *argol*, and consist of potassium bitartrate, with calcium tartrate, coloring and extractive matters, and yeast and other vegetable fragments. *Red argol* is deposited from red wines, and has a brownish color; *white argol*, obtained from white wines, is gray or brownish white. Crude tartar is not used medicinally, and little is collected in the United States; but the importation of it has increased from 6,965,015 pounds in 1876 to nearly 28,000,000 pounds in 1895, and nearly 23,500,000 pounds in 1897, the latter being valued at about $1,900,000. The quantity of crude tartar obtained from American wines is rapidly increasing.

Purification.—Crude tartar is boiled with water, much of the coloring-matter precipitated by the addition of clay, the liquid filtered through animal charcoal or otherwise clarified, and crystallized. The operation has to be repeated several times. The amount of calcium tartrate contained in crude tartar varies between about 5 and 15 per cent. Although this salt is insoluble in water, it dissolves to some extent (more in hot than in cold) solutions of tartrates; hence it can not be completely removed from cream of tartar by simple recrystallization. However, the crystals forming on the side of the crystallizing-vats contain less of this impurity than the crusts deposited at the bottom, and by careful management the amount may be reduced to about 3 per cent. or less.

To obtain potassium bitartrate free from calcium salt, finely powdered cream of tartar is macerated for 24 hours with 8 or 10 per cent. of hydrochloric acid, previously diluted with water; or it is dissolved in boiling water, the same amount of hydrochloric acid added, and the solution continually stirred while it cools. The mother-liquor is drained off, the crystalline powder washed with cold water, and dried. A considerable proportion of potassium bitartrate remains in the mother-liquor, and may be utilized in the preparation of tartaric acid by neutralizing it with lime, when calcium tartrate is deposited.

At the present time large quantities of cream of tartar are obtained in a high state of purity and in the form of fine powder, by what is termed the precipitation method. The lees or acid residues of wine-casks are partially neutralized with sodium carbonate and brought into solution in water, which solution is then allowed to percolate through soda-ash contained in stone cylinders. The solution of potassium and sodium tartrate thus obtained is allowed to crystallize for the purpose of purification, after which the slightly colored crystals are redissolved in water and decomposed by addition of acetic acid, as a result of which acid potassium tartrate, almost absolutely pure, is precipitated in powder-form, while sodium acetate remains in solution.

Properties.—When a hot solution of potassium bitartrate is rapidly cooled, the salt separates in very small crystals, which float on the liquid, and from this behavior it has received the name *cream of tartar*. The larger crystals, which are deposited, were formerly distinguished as *crystalli tartari*. They are rhombic prisms, and when pure are transparent, but as usually seen are more or less opaque from the presence of calcium tartrate. But in this form it is rarely kept in the shops, where it is almost exclusively employed in the form of powder. This is white, somewhat gritty, not altered on exposure, inodorous, and has a pleasant acidulous taste and distinct acid reaction. Potassium bitartrate requires at 25° C. (77° F.) 200 (U. S.), 192 (P. G.) parts, and at 100° C. (212° F.) 16.7 (U. S.), 20 (P. G.) parts of water for solution; it is freely soluble, with the formation of neutral salts, in ammonium and potassium hydroxide solutions, and in solution of alkali carbonates, with the evolution of carbon dioxide. It is insoluble in alcohol, is more soluble in dilute hydrochloric acid than in water, and is precipitated from this solution by alcohol; the solutions in dilute sulphuric and nitric acids, however, when mixed with alcohol, deposit potassium sulphate and nitrate. The solutions in alkaline liquids again deposit the salt on being sufficiently acidulated with hydrochloric, acetic, or other acid. In the aqueous solution of the salt, rendered neutral by potassium or sodium hydroxide test-solution, silver nitrate test-solution produces a white precipitate which, on boiling, becomes black by the separation of metallic silver. If, before boiling, sufficient ammonia-water be added to dissolve the white precipitate, the metal will, on boiling, form a mirror on the sides of the test-tube. When heated in a crucible it evolves inflammable gas and the odor of burning sugar, and leaves a black residue known as *black flux*, which is a mixture of potassium carbonate and charcoal; the latter is finally consumed on continuing the ignition with free access of air, leaving potassium carbonate or *white flux*. These fluxes are often made by deflagration of intimate mixtures of 2 parts of cream of tartar with potassium nitrate, using 1 part of the latter for the black and 4 parts for obtaining the white flux. On subjecting potassium bitartrate to destructive distillation, carbon dioxide, carbonic oxide, and various hydrocarbons are obtained in the gaseous state; also an aqueous liquid containing much acetic acid, a sublimate of pyrotartaric acid, various tarry products, and in the retort potassium carbonate.

Tests.—When potassium bitartrate is treated with a hot solution of potassium hydroxide whatever remains undissolved is impurity. In this way only the coarser adulterations, such as *terra alba*, sand, etc., or calcium tartrate if present as impurity to a considerable extent, can be detected. Cream of tartar has been adulterated with gypsum, chalk, alum, amylaceous substances (stale bread, etc.). These substances are best detected by treating 0.5 Gm. of the powder with 3 Cc. of ammonia-water, wherein it should be completely soluble. The residue left by ammonia will acquire a blue color on the addition of iodine if starch is present; cold dilute hydrochloric acid added to the residue will leave terra alba, starch, and some gypsum undissolved, and produce effervescence if chalk is present.

If 1 Gm. of the salt be well triturated with about 1 Gm. of potassium carbonate and 0.5 Gm. of potassium nitrate, and the mixture heated gradually to dull redness in a porcelain crucible, and, upon cooling, the resulting mass be treated with a slight excess of

diluted hydrochloric acid and filtered, the filtrate should not yield a gelatinous precipitate upon being made slightly alkaline with potassium hydroxide test-solution, soluble in excess of the reagent (absence of alum). If the precipitate be insoluble, it is collected and, after thoroughly washing with hot distilled water and dissolving in hot dilute nitric acid, no yellow precipitate should appear upon the addition of an excess of ammonium molybdate test-solution (absence of phosphates).

Chlorides and sulphates are most conveniently detected in the aqueous solution of cream of tartar, which, after addition of a few drops of nitric acid, should not be precipitated by barium nitrate (sulphates) or silver nitrate (chlorides). The aqueous solution (1 in 20) of the salt, slightly acidulated with hydrochloric acid, to which an equal volume of hydrogen sulphide solution is added, should not give a precipitate or coloration when kept closed in a warm place for at least half an hour, either before or after rendering slightly alkaline with ammonia-water (absence of lead, arsenic, etc.). No odor of ammonia should be evolved on heating the salt with a slight excess of potassium or sodium hydroxide test-solution. If 1 Gm. of potassium bitartrate be thoroughly ignited at a red heat, and the residue extracted with hot water and filtered, the filtrate should require for complete neutralization not less than 10.60 Cc. of half-normal sulphuric acid solution, methyl-orange being used as an indicator.—U. S. Each Cc. of the acid corresponds to 0.09339 Gm. of the salt and 10.60 Cc. corresponds to 0.9899 Gm., or 98.99 per cent. of pure salt. The German Pharmacopœia permits the presence of traces of chloride and of not more than 0.25 per cent. of calcium tartrate. For the detection of the latter it has adopted the test proposed by Biltz: 1 Gm. of the salt is repeatedly agitated and macerated for half an hour with 5 Cc. of 30 per cent. acetic acid; then dilute with 25 Cc. of distilled water, and to the clear decanted liquid add 8 drops of ammonium oxalate test-solution, when it should not become cloudy in less than 1 minute (P. G.). The diluted acetic acid (P. G.) is nearly identical with the acetic acid (U. S.). In the above test with 8 drops of ammonium oxalate solution a turbidity beginning after ½, 1, or 2 minutes indicates respectively $\frac{1}{3}$, $\frac{1}{4}$, or $\frac{1}{6}$ per cent. of calcium tartrate. This test has been omitted from the U. S. P. of 1900. The British demands that 1 Gm. of the salt shall require at least 5.2 Cc. of normal sodium hydroxide solution for neutralization, corresponding to 95.55 per cent., each Cc. of the acid corresponding to 0.18375 Gm. of the salt (Br. molecular weight = 183.75). This result seems contradictory to the further requirement of the Br. that the total amount of impurities should not exceed 2.5 per cent. of the dried salt.

Tartarus Boraxatus, P. G. *Cremor tartari solubilis, Kalium tartaricum boraxatum, Borax tartarisata.—Boro-tartrate of potassium and sodium*, E.; *Tartro-borate de potasse et de soude*, Fr.; *Boraxweinstein*, G.—2 parts of borax are dissolved in 15 parts of distilled water and digested with 5 parts of cream of tartar. When entirely dissolved, the filtered liquid is evaporated with constant stirring, the resulting residue dried in thin layers, and while still warm reduced to powder and preserved in well-corked bottles. —P. G. It is a white, amorphous, deliquescent powder of an agreeably acidulous taste and acid reaction. It is soluble in its own weight of cold and less than half its weight of boiling water, insoluble in alcohol, and when heated is decomposed, leaving a residue of borax, potassium carbonate, and charcoal. The aqueous solution of the salt is not altered by acetic acid or by a small quantity of diluted sulphuric acid, but after the addition of tartaric acid a crystalline precipitate is produced. Moistened with sulphuric acid, the salt imparts a green color to the flame of alcohol. A 10 per cent. aqueous solution should not be altered by ammonium sulphide (metals), should not evolve ammonia on being warmed with potassa, should not be precipitated by ammonium oxalate (calcium), and after the addition of a few drops of nitric acid it should not be precipitated by barium nitrate, and should merely become opalescent with silver nitrate.

Potassii Tartroboras.—*Potassium boro-tartrate*, E.; *Tartrate borico-potassique, Crême de tartre soluble, Tartre boraté*, Fr.; *Borsäureweinstein*, G.—4 parts of cream of tartar, 1 of boric acid, and 10 of water are heated together until dissolved; the solution is evaporated to dryness and the residue powdered.—Fr. Cod. It forms a white inodorous powder or may be obtained in thin transparent scales, has an acidulous taste, is not deliquescent, and dissolves in 2 parts of cold water. When long kept, it becomes less soluble in water, but its solubility is restored on treating it with boiling water.

Action and Uses.—Unlike the other potassium salts of vegetable acids, potassium bitartrate does not render the urine neutral or alkaline; on the contrary, it has a tendency to increase its acidity, and may be employed to neutralize or acidify an alkaline urine.

It resembles the above-mentioned salts, however, in that it produces diuresis, and is employed as a valuable diuretic in dropsy due to acute or chronic nephritis. In the latter disease it is administered in combination with jalap or senna or dissolved in infusion of juniper-berries (1 ounce (30 Gm.) of salt to 1 pint (480 Cc.) of infusion). In acute renal inflammation it should be used without the juniper. In large doses it exercises a laxative influence, and is occasionally combined with sulphur for this effect in the treatment of hemorrhoids. In household medicine it is frequently used to "cool the blood" in mild febrile attacks and skin diseases, and to allay thirst in summer. Added to sweetened water it makes a pleasant, acidulous, refrigerant drink.

The dose of the drug as a diuretic is from ½ to 2 drachms (2–8 Gm.), largely diluted with water; as a laxative, from ½ to 1 ounce (16–30 Gm.).

POTASSII BROMIDUM, *U. S.*, *Br.*—Potassium Bromide.

Kalium bromatum, P. G.; *Bromure de potassium*, Fr.; *Bromkalium, Kaliumbromid*, G.

Formula, KBr. Molecular weight, 118.22.

Potassium bromide should contain not less than 97 per cent. of pure salt.—U. S.

Preparation.—This salt, like many others, is best made on a large scale. One method consists in decomposing a solution of ferrous bromide (obtained by the action of bromine on iron under water) with potassium carbonate, heating the mixture, filtering, evaporating the filtrate, and crystallizing. The reaction is: $FeBr_2 + K_2CO_3 = FeCO_3 + 2KBr$, insoluble ferrous carbonate being precipitated. The latter is very bulky, but by boiling for some time it is converted into a denser ferric hydroxide, which is more readily washed out with water than the carbonate. The process followed by large manufacturers is to add bromine to a solution of potassium hydroxide until the liquid remains colored, evaporate it to dryness, and expose the saline residue, mixed with charcoal, in small portions at a time, to red heat in an iron crucible; the fused mass is treated with water, the resulting solution filtered and set aside to crystallize. When bromine and potassa are brought together, potassium bromide and bromate are formed; thus, $6KOH + 6Br = 5KBr + KBrO_3 + 3H_2O$; by heating the mixed salts with charcoal all bromate is reduced to bromide; thus, $KBrO_3 + 3C = KBr + 3CO$.

Properties.—Pure potassium bromide crystallizes in colorless cubes which are neutral to test-paper. It is met with in commerce in the form of a granular crystalline powder or of cubical crystals, which are white and glossy, and, having been obtained from an alkaline solution, have a slight alkaline reaction. It is permanent in the air, inodorous, has a pungent, saline taste, and when heated decrepitates, melts at 700° C. (1200° F.), and on cooling congeals again to a transparent mass; at a bright-red or at a white heat it is slowly volatilized without decomposition, communicating a violet color to the flame. It is soluble at 25° C. (77° F.) in about 1.5 (2, Br., P. G.) parts of water and in 180 parts of alcohol; in less than 1 part of boiling water, and in 16 parts of boiling alcohol; also soluble in 4 parts of glycerin.—U. S. The aqueous solution yields a white crystalline precipitate on the addition of tartaric acid or of a saturated solution of sodium bitartrate, and on the cautious addition drop by drop of chlorine-water diluted with an equal volume of water liberates bromine, which dissolves in chloroform or carbon disulphide with a reddish-yellow or brown-yellow color; this color should be free from any violet tint (absence of iodide). 1 Gm. of the powdered and dried salt, when completely precipitated by silver nitrate, yields, if perfectly pure, 1.579 Gm. of dry silver bromide. The precipitate is insoluble in nitric acid and in a moderate excess of ammonia-water.

Tests.—If 1 Gm. of the salt be dissolved in 10 Cc. of water and 0.1 Cc. (2 drops) of tenth-normal sulphuric acid be added, no color should be produced by the subsequent addition of a drop of phenolphthalein test-solution, even after heating (limit of alkali). If diluted sulphuric acid be dropped upon crushed crystals of the salt, and the mixture be shaken with 1 Cc. of chloroform, the latter should not assume a pink color (absence of bromate).—U. S. This test depends on the fact that bromic acid acts on hydrobromic acid liberating bromine: $5HBr + HBrO_3 = 3H_2O + 3Br_2$. 10 Cc. of the aqueous solution (1 in 20) should not be rendered turbid by an equal volume of hydrogen sulphide test-solution (absence of metals), P. G.; nor, when acidulated with hydrochloric acid, by 1 Cc. of potassium sulphate test-solution (barium), U. S., P. G.; nor by 1 Cc. of

barium chloride test-solution (sulphate), P. G.; nor be colored blue by 0.5 Cc. of potassium ferrocyanide test-solution after acidifying (iron), P. G. The Br. P. demands the absence of calcium, magnesium, sodium, ammonium, cyanide, thiocyanate, besides heavy metals, and allows only the slightest reactions for chlorides, iodides, and sulphates. The aqueous solution (1 in 20) of the salt, slightly acidulated with hydrochloric acid and mixed with an equal volume of hydrogen sulphide solution, should not give a precipitate or coloration after standing corked in a warm place for at least half an hour, either before or after addition of ammonia-water to slight alkalinity (absence of heavy metals). If 0.3 Gm. of the well-dried salt be dissolved in about 50 Cc. of water, and 2 or 3 drops of potassium chromate test-solution be added, it should require not less than 24.6 Cc., nor more than 25.85 Cc. (not less than 25.11 Cc., nor more than 25.62 Cc., Br.; 25.4 Cc., P. G.) of tenth-normal silver nitrate solution to produce a permanent red color. —U. S. 0.3 Gm. of pure potassium bromide would require 25.38 Cc. of the volumetric solution, while 0.3 Gm. of potassium chloride would require 40.51 Cc.; hence 1 per cent. of chloride is represented by each 0.1513 Cc. of tenth-normal silver solution used in excess of 25.38 Cc. for 0.3 Gm. of the salt; therefore 0.47 Cc. (25.85–25.38 Cc.) excess of silver nitrate solution allowed in titration represents 3.1 per cent. of potassium chloride, assuming this to be the impurity present. If the quantity of silver solution used falls below that theoretically required, it is due to the presence of impurities which do not react with the silver nitrate, or to iodides. As the U. S. P. does not allow the presence of iodide, the lower figure, 24.6 Cc. of silver nitrate solution limits the amount of impurities having no action on it, and corresponds to 96.92 per cent. of bromide. The Br. P. places the limit of chloride at 1.6 per cent., and the P. G. restricts the impurity of chloride to 1.46 per cent. A very delicate test for chloride is the following: To a solution of the salt are added potassium dichromate and sulphuric acid, and the mixture distilled; the distillate will contain chlorochromic anhydride, CrO_2Cl_2, and after neutralization with ammonia will have a yellow color and show the reaction of chromates.

Action and Uses.—The chief influence of potassium bromide, which may be taken as a type of all the bromides which are employed in medicine, is exercised upon the nervous system. Upon the brain it acts as a sedative, its dominant effect being exercised upon that portion of the cerebral cortex which controls voluntary movements. In large doses it also acts as a sedative to the intellectual centres of the brain in the anterior convolutions, and massive doses, or large doses, frequently repeated, probably depress the perceptive centres in the posterior convolutions. Upon the motor pathways of the spinal cord it exercises little effect when given in medicinal amount, but upon the sensory portions of the spinal cord it is distinctly sedative in its influence. Medicinal doses probably have no effect upon the peripheral sensory nerves. It is eliminated from the body in all the secretions, but escapes chiefly through the kidneys. Its elimination is very slow, and for this reason, when administered day after day, it rapidly accumulates in the body, and produces more and more marked effects. The therapeutic deduction to be drawn from this fact is that many patients who require large doses at the beginning of its employment may, after several days, be kept thoroughly under its influence by doses which are not more than half as large as those which were first administered. Upon other portions of the body the bromide of potassium exercises comparatively little effect which can be used advantageously in medicine. When taken for a considerable period of time, particularly if the doses are large, it is very prone to produce acne of the face and back, which eruption progressively increases, both as to its distribution and severity, if the drug is continued, until a large number of well-developed pustules may be present. Associated with this acne the patient is found to be heavy and stupid, and often somnolent, his mental processes being so slow that a considerable length of time is required for him to grasp ideas or to express his thoughts.

The great diminution in reflex activity produced by the action of the drug upon the sensory portions of the nervous system results in a number of conditions which become more and more noteworthy as the use of the drug is continued. Digestion becomes impaired because the benumbing of the sensory nervous apparatus of the stomach results in a lack of recognition on its part of the presence of food, and a consequent failure to promptly secrete an adequate quantity of gastric juice. Constipation develops for similar reasons. The disorder of the digestion and the constipation are also in part due to the depressant influence which is exercised by the potash itself, and it is important to remember when large doses of the bromide of potassium are used that many of the

marked symptoms presented by the patient depend upon the action of the potassium rather than upon the bromine which is associated with it, and for the effects of which the combination has been employed. A few cases of epilepsy have been reported in which, because of idiosyncrasy to the drug, a condition of mental excitement has developed instead of mental sedation, the degree of excitement being so marked that the patient was insane for the time being. These cases are, however, so rare that they are curiosities in medicine. Those physicians who have employed the bromides in large doses and for long periods of time are agreed that the pustular acne, to which reference has already been made, may be diminished in its severity, or prevented from appearing to some extent by careful attention to the condition of the patient's bowels, holding that in many instances the eruption is in part due to the absorption of toxic matter from the alimentary canal. It is also the habit of these physicians to prescribe small doses of Fowler's solution of arsenic during the time that the bromide is being used, not only for its tonic influence, but to exercise a beneficial influence upon the skin.

Bromide of potassium is employed in medicine solely for its influence upon those portions of the nervous system which have already been named. In many instances it is a symptomatic remedy; that is to say, it is of value for the purpose of relieving symptoms which may be annoying, without any expectation that it will relieve the underlying disease. Thus, in epilepsy, the bromide of potassium is a standard palliative. In this malady it does good by depressing or quieting the motor area of the cerebral cortex, so that its disordered cells will not send out convulsive impulses. It probably does good in this disease, too, by its sedative influence upon the sensory portions of the system whereby excitation of the motor cortex of the brain is prevented by reason of the fact that the drug depresses the sensory pathways in the spinal cord, and so prevents peripheral impulses from reaching the central nervous system. When used in epilepsy it must be given in large enough doses to produce distinct physiological effects. In the majority of instances the best results which can be obtained from its use consist in the diminution in the frequency and severity of the fits. Occasionally, if all other conditions in and about the patient are favorable, it may diminish the frequency of the attacks to so great an extent as to produce a virtual cure, but these cases are, unfortunately, in the minority. Care must be taken that the drug is not used so long and in such full doses as to add its depressant effects to the mental deterioration which sometimes develops in epileptics. Its administration, therefore, must be cautious and carefully watched. Next to its employment in epilepsy, it has its greatest field of usefulness in the control of various manifestations of nervous excitation, varying from the mental distress and nervous irritability of overwrought men and women to the manifestations of fully developed hysteria. Here, again, it relieves the symptoms without curing the underlying cause of the condition. In infantile convulsions it is a most useful drug because of the physiological action already described. Under these circumstances, it may be given either by the mouth or by the rectum, according to the condition of the patient's stomach. In tetanus and strychnine-poisoning it does good by quieting the sensory portions of the spinal cord. One or two drachms are required in cases of this kind, and it may be necessary to repeat the dose several times. Certain forms of neuralgia, dependent upon irritability of the nervous system, may also be benefited by its use, particularly if it is combined with citrate of caffeine and one of the coal-tar products, this combination being the basis of most of the popular headache remedies of the day.

In persistent vomiting, due to irritability of the vomiting centre in the medulla, the bromide of potassium is a sovereign remedy. As a rule, it must be given by the rectum, as the stomach is not retentive enough to permit its absorption before it is vomited. In delirium tremens it is often used in full doses for its sedative effect, particularly if it is combined with chloral. Among the other uses of the bromide may be mentioned its employment in cases of hyperchlorhydria, in which condition it does good by diminishing the reflex activity of the nervous supply of the stomach. It is also of value in cases of sexual excitement or nymphomania, in irritability of the bladder, and in certain forms of nervous dysmenorrhœa. Certain physicians are in the habit of employing it, in moderate doses, for the relief of cardiac palpitation affecting neurotic persons or those who use tobacco to excess.

The dose of bromide of potassium varies from 5 to 60 grains (0.3–4 Gm.). For children the dose varies from 2 to 20 grains (0.05–1.3 Gm.).

POTASSII CARBONAS, *U. S., Br.*—Potassium Carbonate.

Kalium carbonicum, P. G.; *Potassii carbonas purus, Sal tartari.—Carbonate of potash, Salt of tartar*, E.; *Carbonate de potasse*, Fr.; *Kaliumcarbonat, Kohlensaures Kali*, G.

Formula, K_2CO_3. Molecular weight, 137.27.

Potassium carbonate should be kept in well-stoppered bottles and contain, when thoroughly dried, at least 98 per cent. of pure salt.—U. S.

Origin and Preparation.—Potassium carbonate is contained in many mineral waters, and is met with in the animal economy chiefly after the administration of potassium citrate or tartrate. Plants take their inorganic constituents from the soil, and when incinerated leave them behind as *ashes*. The ash of most plants contains potassium, sodium, calcium, and magnesium in combination with chlorine, carbonic, sulphuric, phosphoric, and silicic acids, usually ferric oxide, and occasionally some other elements. As a rule, plants grown near the seashore yield an ash rich in sodium, and those grown inland an ash in which potassium salts predominate. Succulent plants or parts of plants generally yield a larger percentage of ash (calculated for the exsiccated substance) than dry or woody parts. The amount of ash and its constituents necessarily varies to a certain extent, being influenced by the nature of the soil, the age of the plant, and by various other causes; the composition of the ash and of its soluble portion must therefore vary for the same species.

For a long time this article was chiefly obtained in those countries, as in some parts of Europe and North America, where wood is cheap or where its transportation to more remunerative markets is too costly, by burning the wood and lixiviating the ashes. The solution is obtained as concentrated as possible by passing the weaker liquids through fresh portions of ash, afterward evaporated and heated in iron vessels, so that on cooling it will solidify to a hard mass; this constitutes the *crude potash* of the market. This crude potash is of a more or less deep-brown, reddish-brown, or bluish color, due to organic impurities, and to iron, copper, or manganese; it is deliquescent on exposure and has a very caustic taste. It is not recognized by any of the pharmacopœias.

Large quantities of carbonate of potash are at present prepared from the ash obtained from the residue of the beet-sugar manufacture, which contains about one-third its weight of this salt, and is freed from other potassium and sodium salts by allowing these to crystallize from concentrated solutions at different temperatures. On washing the fleece of sheep with water, evaporating the solution, and igniting the residue, an ash is obtained containing but a small percentage of sodium salts and a larger proportion of potassium chloride and sulphate. The potassium salts obtained in these processes, notably in the former one in large quantities, also the potassium salts from the Stassfurt mines, are by suitable processes converted into potassium sulphate, and this salt into carbonate by a process similar to that of Leblanc for soda (see SODII CARBONAS), by heating the sulphate with lime and charcoal, whereby potassium carbonate and an insoluble calcium oxysulphide are formed.

Various methods of obtaining potassium carbonate from other sources have been recommended, and to some extent are used. E. Meyer (1857) proposed to ignite an intimate mixture of 10 parts of *feldspar* (aluminum and potassium silicate) with from 14 to 18 parts of lime, to boil the mass with water under pressure, and to evaporate the solution, at the same time conducting the products of combustion over the liquid, in order to convert the caustic potassa into carbonate and to precipitate the alumina which was in solution.

Another method recently applied consists in bringing together potassium chloride, crystallized magnesium carbonate, $MgCO_3.3H_2O$ (see MAGNESII CARBONAS), in water, and passing into the mixture carbon dioxide under pressure, when a double carbonate is formed, $KHMg(CO_3)_2 + 4H_2O$, which is difficultly soluble in water and even in dilute acids. By heating this salt with water to 120° C. (248° F.) it is decomposed, potassium carbonate going into solution.

Potassium carbonate from wood-ashes, at the present time, scarcely makes up one-half of the total production, and the supply from this source is becoming less each year.

When crude potash (*black salts*) is heated in a reverberatory furnace, organic impurities are burned out and a mass is obtained which, when cold, has a bluish-white color and is known as *Pearlash*. This is official in the P. G. as Kalium Carbonicum Crudum

(Potasche), and is required to contain for the anhydrous salt 90 per cent. of potassium carbonate, and 1 Gm. should require at least 13 Cc. of normal hydrochloric acid for neutralization.

It is a tedious matter to prepare pure potassium carbonate from pearlash, as the carbonate does not crystallize well and is very soluble in water, which facts render it almost impossible to get rid of all impurities. A pure salt can be obtained more expeditiously in an indirect way. When an organic salt of potassium is ignited, the residue left contains potassium carbonate. Cream of tartar, being the most common salt available for this purpose, was formerly more extensively employed than at present for preparing pure potassium carbonate; hence the name *salt of tartar*, which is, however, in the United States usually employed as a synonym for *purified* potassium carbonate. In making carbonate from potassium bitartrate, the latter is usually mixed with saltpeter, which should be entirely free from chloride, and then deflagrated by throwing the mixture in small portions into a red-hot crucible, when the potassium of both the bitartrate and nitrate is left behind as carbonate. In this way, *black* and *white flux* are prepared, of which the latter usually contains potassium nitrite. By exhausting the black flux with water and evaporating the solution a very pure potassium carbonate is obtained.

Pearlash may be considerably purified by extracting it with an equal weight of cold water, by which most of the less soluble impurities remain behind, and evaporating the solution to dryness. By converting the carbonate thus obtained into bicarbonate the latter salt may be obtained nearly chemically pure, and when heated to redness will give off water and carbon dioxide, and leave an equally pure carbonate; $2KHCO_3$ yields $K_2CO_3 + H_2O + CO_2$. In these operations only silver or clean iron vessels should be employed, for reasons explained under POTASSIUM HYDROXIDE.

Properties.—Potassium carbonate in its pure state is a white inodorous salt, sometimes crystalline, but usually in the form of a granular powder, which has a strong alkaline reaction and a strongly alkaline but scarcely a caustic taste, and is deliquescent in the air, forming a colorless or yellowish liquid of an oily appearance (*Oleum tartari per deliquium*). It is soluble in 0.91 part of cold water and in two-thirds its weight of boiling water, and from its concentrated solution may with some difficulty be obtained in transparent crystals containing 16.36 per cent. of water. It is insoluble in alcohol, dissolves in dilute acids with effervescence, and has the chemical behavior of potassium salts. A fragment of the salt attached to the loop of a platinum wire should impart a pure violet color to a non-luminous flame. A solution of the salt in a slight excess of diluted hydrochloric acid will give a yellow precipitate with platinic chloride test-solution, a white crystalline precipitate with a saturated solution of tartaric acid, and a yellow one with sodium cobalt nitrite solution. The salt when heated to 130° C. (266° F.) loses all the water it may have retained or absorbed (about 16 per cent., Br.); this exsiccated salt melts at a bright-red heat, and slowly volatilizes at a white heat.

Tests.—The aqueous solution (1 in 20), slightly acidulated with hydrochloric acid and mixed with an equal volume of hydrogen sulphide solution, should not give a precipitate or coloration after standing corked in a warm place for at least ½ hour, either before or after adding ammonia-water to slight alkalinity (absence of metallic impurities). If 5 Cc. of the aqueous solution be carefully mixed with an equal volume of concentrated sulphuric acid, and after cooling, 3 Cc. of ferrous sulphate test-solution be poured upon it so as to form a separate layer, no brown color should appear at the line of contact (absence of nitrate). No residue should be left on dissolving 1 Gm. of the salt in 20 Cc. of water (absence of earthy impurities). 20 Cc. of a solution of the salt (1 in 20) acidulated with hydrochloric acid should not be colored blue by 0.5 Cc. of potassium ferrocyanide test-solution (iron).—P. G. The 1900 U. S. P. has dropped the tests for thiosulphate, sulphate, sulphide, cyanide, and limit of chloride, for which see U. S. P., 1890, and the preceding edition of this book. The Br. P. and P. G. still retain tests for these impurities. 1 Gm. of the salt, weighed after thoroughly drying at 130° C. (266° F.), dissolved in about 50 Cc. of water, should require not less than 14.28 Cc. of normal sulphuric acid for neuralization, with methyl-orange as indicator. —U. S. 1 Cc. of the acid represents 0.068635 Gm. of the salt, hence 14.28 Cc. of the acid corresponds to 98 per cent. of pure salt in the dried specimen. According to the P. G., 1 Gm. of the salt, not dried, should require not less than 13.84 Cc. of normal acid, corresponding to 95 per cent. According to the Br., 1 Gm. should require at least 11.9 Cc. of normal sulphuric acid for neutralization, corresponding to 82 (81.64) per

cent. of anhydrous carbonate. Before applying the volumetric test the absence of notable quantities of sodium carbonate should be proved.

Liquor Kali Carbonici.—11 parts of pure potassium carbonate are dissolved in 20 parts of distilled water; the solution has the specific gravity 1.330 to 1.334, and 3 parts of it should contain 1 part of potassium carbonate.—P. G.

Potassii Percarbonas.—*Potassium percarbonate.* $K_2C_2O_6$.—This salt is obtained by passing an electric current through a saturated solution of potassium carbonate at —10° C. (14° F.). When dry, it is colorless and stable; but when moist, it has a bluish color and decomposes. Cold water decomposes it slowly, but when heated the action is more rapid: $K_2C_2O_6 + H_2O = 2KHCO_3 + O$. It is a good oxidizing agent, decolorizing indigo, etc. With dilute acids hydrogen peroxide is formed. It has been proposed to use the salt to bleach cotton-wool, silk, hair, wool, and feathers.

Action and Uses.—Potassium carbonate may be given for the same purposes as potassium bicarbonate (which see), but is rarely employed, because it is more apt to produce irritation of the stomach than is the latter drug. In concentrated solution it exercises a decided corrosive influence upon mucous membranes with which it comes in contact, and has produced death when taken into the stomach. The antidotes to it are vegetable acids and fixed oils. In the form of lotion, bath, and ointment it is used in some cutaneous diseases. The lotion should contain from 1 to 2 drachms (4–8 Cc.) of potassium carbonate to the pint (480 Cc.) of water, and the ointment 10 to 40 grains (0.6–2.60 Gm.) to the ounce (30 Cc.). The dose of potassium carbonate is from 10 to 30 grains (0.60–2 Gm.), well diluted in water.

POTASSII CHLORAS, *U. S., Br.*—Potassium Chlorate.

Kalium chloricum, P. G.; *Kali oxymuriaticum, Kali muriaticum oxygenatum.—Chlorate of potash*, E.; *Chlorate de potasse*, Fr.; *Kaliumchlorat, Chlorsaures Kali*, G.

Formula, $KClO_3$. Molecular weight, 121.68.

Potassium chlorate should be kept in glass-stoppered bottles and contain not less than 99 per cent. of pure salt. Great caution should be observed in handling it, as dangerous explosions are liable to occur when it is mixed with organic matter (cork, tannic acid, sugar, etc.) or with sulphur, antimony sulphide, phosphorus, or other easily oxidizable substances, and the mixture subjected to heat, or trituration, or concussion.—U. S.

Preparation.—At present potassium chlorate is largely made by a process similar to that given in the British Pharmacopœia, which consists in passing chlorine gas into water holding lime, or preferably magnesia, in suspension, by which means chloride and hypochlorite of the respective metals are formed. The latter salt is decomposed by heat into chlorate and chloride, and upon treating the solution with potassium chloride a reaction sets in, by which potassium chlorate and calcium or magnesium chloride are formed, the latter salts remaining in solution, while the potassium chlorate crystallizes out. Magnesia is preferred to lime, as potassium chlorate is less soluble in solution of magnesium chloride than of calcium chloride. The reactions involved may be expressed as follows: $2Ca(OH)_2 + Cl_4 = Ca(ClO)_2 + CaCl_2 + 2H_2O$; $3Ca(ClO)_2 = Ca(ClO_3)_2 + 2CaCl_2$; $Ca(ClO_3)_2 + 2KCl = 2KClO_3 + CaCl_2$.

Large quantities of the salt are produced both in this country and in Europe by a process which consists in passing an electric current through a heated solution of potassium chloride, whereby chlorine collects around one pole (the positive) and potassium hydroxide around the other. The solution of potassium hydroxide by a process of circulation is carried to the compartment of the next cell containing the positive pole, and so on, by which it comes in contact with chlorine and forms chlorate, which continually crystallizes out. The change is most simply expressed thus: $2Cl + H_2O = 2HCl + O$; $KOH + HCl = KCl + H_2O$; $KCl + 3O = KClO_3$.

The salt is also manufactured by boiling together in solution chlorinated lime and potassium chloride: $KCl + 3CaOCl_2 = KClO_3 + 3CaCl_2$. On cooling, the chlorate crystallizes out.

Potassium chlorate seems to have been known to Glauber (1657); it was described by Higgins (1786) as a kind of saltpeter, and was recognized by Berthollet (1786) as the compound of a hitherto unknown acid.

Properties.—Potassium chlorate crystallizes in colorless shining plates or in short monoclinic prisms. It is inodorous, has a cooling, saline taste, and neutral reaction, is

permanent in the air, melts without decomposition at 334° C. (633.2° F.), gives off oxygen above 352° C. (665.6° F.); at the same time it forms potassium perchlorate, and at a higher temperature, above 400° C. (752° F.), parts with all its oxygen (39.2 per cent. of its weight), leaving 60.8 per cent. of potassium chloride having the properties described below. It requires, at 25° C. (77° F.), 16 U. S., 16 Br., P. G., parts of water for solution, or 1.7 U. S., 3 Br., 2 P. G., parts of boiling water.—U. S.

Ammonium nitrate increases, but ammonium chloride and acetate decrease the solubility in water (Pearson, 1869). The salt is slightly soluble in diluted alcohol, but is insoluble in absolute alcohol. As ordinarily met with in commerce, the salt contains traces of calcium chloride, from which it is freed by dissolving it in 2 or 3 times its weight of hot distilled water, and stirring the solution while cooling; it will then be obtained in small crystals, which, after draining and washing with cold water, are pure. The saturated aqueous solution of the salt yields with tartaric acid a white precipitate of potassium acid tartrate, and with platinic chloride solution a copious yellow precipitate is produced. When strong sulphuric acid is added to potassium chlorate, *chlorine dioxide*, ClO_2, is formed: this is a yellow heavy gas, which, in the presence of combustible matter or by a slight elevation of temperature, is decomposed with a powerful explosion into oxygen and chlorine. On adding hydrochloric acid to potassium chlorate a deep-yellow, dangerously explosive gas, the *euchlorine* of Davy, is produced; it is a mixture of chlorine and chlorine dioxide.

Tests.—The aqueous solution, containing 5 (Br. P., P. G.) per cent. of potassium chlorate, should not be precipitated by barium chloride (sulphate), silver nitrate (chloride), or ammonium oxalate (calcium salt). The U. S. P., 1900, has omitted these three tests as the impurities are innocuous, and with a limit of purity of 99 per cent. may be disregarded. If 1 Gm. of the salt, 5 Cc. of water, 5 Cc. of potassium hydroxide test-solution, and about 0.2 Gm. of aluminum wire, contained in a 40 Cc. test-tube, into the upper part of which is inserted a pledget of purified cotton, be heated on a water-bath for 15 minutes, no blue coloration should be imparted to moistened red litmus-paper placed over the mouth of the tube (limit of nitrates and nitrites). The aqueous solution (1 in 20) of the salt should not become discolored upon adding ammonium sulphide test-solution (absence of heavy metals).

Action and Uses.—The chlorate of potassium is a drug which has a very limited range of usefulness. At one time it was largely employed with the idea that by its administration the body might be provided with an additional quantity of oxygen over and above that taken from the air by the lungs. We now know that the quantity of oxygen which can be obtained from any dose of chlorate of potassium which is safe to administer is too small to be of any use, and we also know that chlorate of potassium does not part with its oxygen until it is heated to a temperature far higher than that of the human body. Increasing experience has also taught us that, next to the cyanide of potassium, it is one of the most poisonous of the potash salts which are used in medicine, not only exercising a destructive action upon the blood and producing methæmoglobin, but also by its depressant action upon the nervous system and by its irritant effect upon the kidneys. It is also capable of producing widespread fatty degeneration if taken in poisonous doses. In a number of cases its use in very large doses has resulted in death. In all probability its administration to patients whose kidneys are impaired by disease has in the past hastened dissolution, particularly as some practitioners have given it internally in large doses in the treatment of diphtheria with the idea that it would favorably affect the diseased mucous membrane of the pharynx or provide more oxygen to the tissues.

The drug escapes from the body by all the secretions, and particularly in the saliva. Because of its elimination through the salivary glands it exercises a continual influence upon the oral mucous membrane, and in cases in which the kidneys and stomach are healthy it may be given in small doses internally in the treatment of aphthous stomatitis with advantage. It is also used as a gargle, in the strength of from 2 to 10 grains (0.1–0.60 Gm.) to the ounce (30 Cc.), in cases of simple and follicular pharyngitis. Certain English practitioners have also advised its internal use in women who have a tendency to abort. How it can do good under these circumstances it is difficult to understand.

The dose of chlorate of potassium for internal use is 2 to 10 grains (0.1–0.60 Gm.).

POTASSII CITRAS, *U. S., Br.*—Potassium Citrate.

Kalium citricum.—Citrate of potash, E.; *Citrate de potasse,* Fr.; *Kaliumcitrat, Citronsaures Kali,* G.

Formula, $K_3C_6H_5O_7 + H_2O$ or $C_3H_4(OH)(COOK)_3 + H_2O$, U. S.; $C_3H_4(OH)(COOK)_3$, Br. Molecular weight, 322.08.

Potassium citrate should be kept in well-stoppered bottles and contain not less than 99 per cent. of pure salt.—U. S.

Preparation.—The pharmacopœias give no formula for preparing this salt. It may be prepared by neutralizing a solution of citric acid with potassium carbonate, or bicarbonate, and evaporating the solution to dryness, with constant stirring, so as to obtain the salt in small granules. The finished product retains a little over 5.5 per cent. of water, but should be free from impurities; the commercial article is frequently acid, showing imperfect saturation. As the salt is deliquescent, it must be well protected against air. The reaction taking place is: $3KHCO_3 + H_3C_6H_5O_7.H_2O = K_3C_6H_5O_7 + 3CO_2 + 4H_2O$. On evaporating the clear solution the heat should not be permitted to rise high enough to burn the salt. When dry, it may be triturated in a warm mortar; and may thus be rendered uniformly pulverulent.

Properties.—Potassium citrate is a white granular inodorous powder having an alkaline reaction to litmus-paper, but no effect on phenolphthalein, and a saline, cooling (feebly acid, Br.) taste. It is deliquescent on exposure, dissolves in 0.5 part of water at 25° C. (77° F.) (U. S.), and is more freely soluble in boiling water. It is insoluble in absolute alcohol, and forms with dilute alcohol a solution upon which a stronger alcohol floats. Its solution gives a white crystalline precipitate with a saturated solution of sodium bitartrate, but it remains clear on the addition of calcium chloride till it is boiled, when a white precipitate of calcium citrate takes place, which is readily soluble in acetic acid. From its concentrated solution it may be procured in transparent needles which have the above composition and contain $H_2O = 5.55$ per cent. This water of crystallization is not completely expelled until the heat is raised to about 200° C. (392° F.), a portion being retained by the salt as prepared by the above process. At about 230° C. (446° F.) the salt begins to turn brown, and at a higher temperature is completely decomposed, inflammable vapors having a very pungent, acid odor being given off, while potassium carbonate remains behind mixed with charcoal, which latter is with difficulty completely consumed by continued heating. The salt, heated with strong sulphuric acid, yields a brown liquid, gives off an inflammable gas (carbonic oxide), and evolves the odor of acetic acid. If 1 Gm. of potassium citrate be thoroughly ignited at red heat, and the residue extracted repeatedly with hot water, the filtrate on cooling should require for complete neutralization not less than 18.4 Cc. of half-normal hydrochloric acid, methyl-orange being used as indicator. This corresponds to 98.77 per cent. of pure salt. Each Cc. of the acid represents 0.05368 Gm. of the salt. This test recognizes a salt containing 5.55 per cent. or less of water, while the Br. P. requires the anhydrous salt, of which 1 Gm. heated to redness until gases cease to be evolved, leaves an alkaline residue requiring for exact neutralization at least 9.7 Cc. of normal solution of sulphuric acid, corresponding to 98.33 per cent. of anhydrous salt.

Tests.—The aqueous solution of the salt should not be colored red by a drop of phenolphthalein test solution nor effervesce on the addition of acetic acid (absence of carbonate) or produce with it a crystalline precipitate (absence of tartrate). The aqueous solution (1 in 20), slightly acidulated with acetic acid, should not give a precipitate with hydrogen sulphide, neither before nor after addition of ammonia-water, after standing corked in a warm place for at least half an hour (absence of heavy metals).

Action and Uses.—Potassium citrate is an efficient refrigerant, diaphoretic, and diuretic in acute febrile attacks, especially in children. Its efficiency in fever may be enhanced by the adding to its solution spirit of nitrous ether and small doses of aconite. Under its influence highly acid and irritating urine becomes neutral or alkaline and bland. The official solution of the drug (Liquor Potassii Citratis) is a convenient substitute for the old neutral mixture made from lemon-juice and potassium bicarbonate or carbonate, but it lacks the pleasant taste of the latter preparation. Potassium citrate is given in the dose of from 5 to 30 grains (0.3–2 Gm.), the liquor potassii citratis, in the dose of from 2 to 8 drachms (8–30 Cc.).

POTASSII CITRAS EFFERVESCENS, *U. S.*—Effervescent Potassium Citrate.

Preparation.—Potassium citrate, 200 Gm.; citric acid, in uneffloresced crystals, 162 Gm.; sodium bicarbonate, dried and powdered, 477 Gm.; tartaric acid, dried and powdered, 252 Gm. Dry the potassium citrate on a water-bath until it ceases to lose weight; powder and mix it intimately with the citric and tartaric acids, then thoroughly incorporate the sodium bicarbonate. Place the mixture on a plate of glass or in a suitable dish, in an oven heated between 93° and 104° C. (199.4° and 219.2° F.). When the mixture, by the aid of careful manipulation with a wooden spatula, has acquired a moist consistence, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Keep it in well-stoppered bottles. The yield is about 1000 Gm.—U. S.

When the salt is dissolved in water, the sodium bicarbonate is decomposed by the free acids, causing effervescence by the escape of carbon dioxide, and the formation of sodium citrate and sodium tartrate. 1 part of tartaric acid decomposes 1.12 parts, and 1 part of citric acid decomposes 1.203 parts of sodium bicarbonate. Hence the quantity of the respective acids in the formula will decompose 477 Gm. of the bicarbonate, which is the weight given in the official formula. Upon solution of the effervescent salt in water, the carbonic acid present renders the taste agreeably acidulous and refreshing. The temperature prescribed by the pharmacopœia must not be exceeded, to avoid fusion and subsequent decomposition, which would color the mixture and develop a disagreeable, bitterish taste.

Action and Uses.—This preparation affords a convenient and pleasant means of administering potassium citrate. It is given in doses of from 1 to 2 drachms (4–8 Gm.) in water, to be drunk while effervescing.

POTASSII CYANIDUM, *U. S.*—Potassium Cyanide.

Kalium cyanatum, Cyanuretum potassicum s. kalicum.—Cyanure de potassium, Fr.; *Kaliumcyanid, Cyankalium*, G.

Formula, KCN. Molecular weight, 64.7.

The salt should be kept in well-stoppered bottles and should contain not less than 95 per cent. of pure potassium cyanide.—U. S. It has been dropped from the Br. (1898).

Preparation.—Potassium cyanide of the purity required by the U. S. Pharmacopœia is best prepared by generating hydrocyanic acid from 2 parts of potassium ferrocyanide with the requisite quantity of sulphuric acid, and conducting the gas into a solution of 1 part of potassium hydroxide in 5 or 6 parts of strong alcohol; the bulky crystalline precipitate is drained upon a funnel, washed with strong alcohol, and dried between bibulous paper at a moderate heat.

Another process for obtaining pure potassium cyanide consists in heating dry potassium ferrocyanide to low redness, excluding the air until the residue has cooled. Nitrogen is liberated and escapes, and the potassium cyanide remains mixed with carbide of iron; $K_4Fe(CN)_6$ yields $4KCN + FeC_2 + N_2$. Air is excluded to prevent oxidation of cyanide to cyanate. The cold mass is extracted with hot 60 per cent. alcohol, and the solution evaporated, when pure cyanide is obtained. The mass can also be extracted with hot water, but on evaporating this solution some cyanide is decomposed into ammonia and potassium formate and a less pure product results: $KCN + 2H_2O = HCOOK + NH_3$.

F. and E. Rogers (1834) devised a process which is extensively used on a large scale. It consists in heating desiccated potassium ferrocyanide (8 parts) with potassium carbonate (3 parts) to redness, until the mass ceases to effervesce, and pouring out the upper white layer, which is free from the black residue of iron, on a slab. The reaction is explained by the equation, $2K_4Fe(CN)_6 + 2K_2CO_3 = 10KCN + 2KCNO + Fe_2 + 2CO_2$, showing that, besides cyanide, potassium cyanate is also formed, carbon dioxide is evolved, and iron is separated in the metallic state: the cyanate may be removed by means of alcohol or carbon disulphide. Both salts must be well dried before they are

mixed, otherwise considerable ammonia is given off; and if the carbonate is contaminated with sulphate, the fused mass will contain a corresponding amount of potassium sulphide. A portion of the product remains in the crucible with the iron; but if it is dissolved with water, it becomes contaminated again with potassium ferrocyanide, which may be regenerated by digestion with sulphide of iron and crystallization to free it from potassium sulphide. The commercial cyanide prepared thus is usually very impure, containing hydroxide, carbonate, cyanate, and formate of potassium, sometimes as much as half the weight of the product. It is known in commerce as *Liebig's cyanide.*

A very pure cyanide is now made by fusing together anhydrous potassium ferrocyanide and metallic potassium and filtering the molten mass through porous clay. The reaction is: $K_4Fe(CN)_6 + K_2 = 6KCN + Fe$. For commercial purposes a mixed cyanide of potassium and sodium is produced by the same method, except that in place of metallic potassium the less expensive sodium is used.

Properties.—Thus prepared, potassium cyanide is a white granular powder consisting of minute transparent cubes, or after melting at a dull-red heat it forms on cooling a white, opaque crystalline mass. When perfectly dry, it is inodorous; but when moist, it is decomposed by the carbon dioxide of the atmosphere and has the odor of hydrocyanic acid. It has an alkaline and bitter taste, reacts strongly alkaline upon test-papers, is deliquescent on exposure, and is freely soluble in water, but is nearly insoluble in absolute alcohol. 80 parts of boiling 90 per cent. alcohol dissolve 1 part of the cyanide; weaker alcohol dissolves it in larger proportion. The aqueous solution dissolves iron, zinc, copper, and nickel, with the evolution of hydrogen, and, in the presence of oxygen, also silver and gold. The solution yields with a saturated solution of sodium bitartrate a white crystalline precipitate, and with sodium cobaltic nitrite test-solution a copious yellow precipitate is produced. The aqueous solution is decomposed on exposure to the air, absorbs carbon dioxide, becomes brown, and deposits a dark-brown precipitate; on boiling, it is partly decomposed, yielding ammonia and potassium formate. The salt fused in contact with the air is partly oxidized to cyanate, and if fused with sulphur yields potassium sulphocyanate.

Impure potassium cyanide, as obtained by the first process, and which is extensively used in the arts, has similar properties, but is in white, opaque pieces. When dissolved in water the cyanate contained in it is gradually decomposed, with the formation of potassium and ammonium carbonates; $2KCNO + 4H_2O$ yields $K_2CO_3 + (NH_4)_2CO_3$.

Tests.—The impurities likely to be present in medicinal potassium cyanide are carbonate and chloride. A solution of the salt in 20 parts of water should not effervesce with hydrochloric acid or should disengage merely isolated gas-bubbles (limit of carbonate). After the acid has been added in slight excess, a drop of ferric chloride test-solution should produce neither a blue (absence of ferrocyanide) nor a red color (sulphocyanate). A few drops of the aqueous solution give with silver nitrate test-solution a white precipitate, which is soluble in an excess of the solution of potassium cyanide, also in ammonia-water, and in concentrated nitric acid (distinction from silver chloride). If 5 Cc. of the solution be shaken with a few drops of ferrous sulphate test-solution and ferric chloride test-solution, and a slight excess of hydrochloric acid then added, a precipitate of Prussian blue will be produced. On heating to redness a mixture of 1 part of the salt with 3 parts of ammonium carbonate, dissolving the residue in water, and acidulating with nitric acid, the solution should give no (or only a faint) turbidity with silver nitrate (chloride). The U. S. Pharmacopœia (1900) has dropped this test. If 1 Gm. of the salt be dissolved in distilled water to the volume of 100 Cc., then 64.7 Cc. of this solution mixed with 5 Cc. of ammonia-water and 3 drops of potassium iodide test-solution should require not less than 47.5 Cc. of tenth-normal silver nitrate solution before the appearance of a permanent precipitate (each Cc. of the silver solution indicating 2 per cent. of pure potassium cyanide).—U. S. In the titration, silver cyanide, which is at first formed, remains dissolved in the remaining unconverted alkali cyanide. As soon as exactly one-half of the hydrocyanic acid has been converted into silver cyanide, as shown by the equation, $2KCN + AgNO_3 = AgCN.KCN + KNO_3$, the solution becomes cloudy by the precipitation of silver iodide, which is insoluble in the ammonia-water. Potassium iodide solution thus acts as an indicator to show when exactly half of the cyanide has been titrated, which is taken as the end-point. Hence, from the equation, it follows that 1 molecule of $AgNO_3$ is equivalent to 2 molecules of KCN (molecular weight, 64.7), or 1 Cc. of tenth-normal solution of silver nitrate is equivalent to 0.01294 Gm. of KCN,

which is 2 per cent. of 0.647 Gm. of the alkali cyanide contained in the 64.7 Cc. of solution taken for the assay. Owing to the frequency with which sodium cyanide is found in potassium cyanide, the titration method does not give the true amount of potassium salt, since it does not distinguish between cyanides of potassium and sodium, but it does give the true amount of hydrocyanic acid which is in combination. If the salt contains only potassium cyanide besides other foreign substances, 95 per cent. of KCN required by the U. S. P. would represent 39.4 per cent. of HCN. It is immaterial if the salt contains sodium cyanide as far as its efficiency is concerned, as a mixed cyanide containing 39.4 per cent. HCN has the same efficiency as potassium cyanide alone containing 95 per cent. KCN. The Cc. of tenth-normal silver solution used multiplied by 0.00537 gives the weight of HCN in the amount of salt titrated, whether the latter be pure KCN or a mixtura of KCN and NaCN.

Potassium cyanide is used extensively in the arts in electroplating with gold, silver, and nickel, in photography, in extracting gold and silver from ores and fine residues or "tailings."

Action and Uses.—Potassium cyanide possesses an identical physiological action with hydrocyanic acid, for which it may be substituted (see ACIDUM HYDROCYANICUM DILUTUM). It has the advantage over dilute hydrocyanic acid in being more stable and uniform in strength. Overdoses are as rapidly lethal as those of the latter drug. In addition to its internal use a solution containing 2 to 4 grains (0.10–0.25 Gm.) of the drug to the ounce (30 Cc.) of water has been employed as a sedative application for the relief of headache and neuralgia. To remove the stain of silver nitrate from the skin, muslin, linen, etc., a solution of potassium cyanide, 5 to 10 grains (0.3–0.60 Gm.) to the ounce (30 Cc.) of water, is serviceable. A more efficient solution for this purpose contains 2½ drachms (10 Gm.) of potassium cyanide, 15 grains (1 Gm.) of iodine in 3 ounces (90 Cc.) of water. Potassium cyanide is given in the dose of from $\frac{1}{12}$ to $\frac{1}{8}$ grain (0.005–0.008 Gm.).

POTASSII DICHROMAS, *U. S., Br.*—Potassium Dichromate.

Potassii bichromas, U. S., 1890; *Kalium dichromicum*, P. G.—*Bichromate of potash, Red chromate of potassium*, E.; *Bichromate de potasse*, Fr.; *Kaliumdichromat, Doppeltchromsaures Kali*, G.

Formula, $K_2Cr_2O_7$. Molecular weight, 292.28.

Potassium dichromate should contain not less than 99 per cent. of the pure salt.—U. S.

Origin.—The metal *chromium* was discovered by Vauquelin in 1797 in a Siberian mineral which is composed of lead chromate, but it is more abundantly found as *chrome iron ore*, which is a compound of chromic and ferrous oxides, $FeO.Cr_2O_3$. It is met with in several localities in the United States, in Russia, and in Sweden, and is used in preparing the dichromate.

Preparation.—The finely ground chrome-iron ore, mixed with potassium carbonate and calcium hydroxide or carbonate, is roasted in a reverberatory furnace, which causes the separation of all iron in the form of ferric oxide and the production of potassium chromate from the newly formed chromic acid; lime or chalk is added simply to prevent fusion of the mixture. The following equation explains the reaction: $2FeOCr_2O_3 + 4K_2CO_3 + 7O = Fe_2O_3 + 4K_2CrO_4 + 4CO_2$. After the roasting or oxidation has been completed the mass is lixiviated with water, which dissolves the yellow potassium chromate; the latter salt, upon addition of sulphuric acid, yields potassium dichromate and sulphate, the two salts being separated by crystallization: $2K_2CrO_4 + H_2SO_4 = K_2Cr_2O_7 + K_2SO_4 + H_2O$. In order to explain the constitution of dichromates it must be assumed that chromic anhydride is capable of forming two acids, namely, $CrO_3 + H_2O = H_2CrO_4$, chromic acid, and $2CrO_3 + H_2O = H_2Cr_2O_7$, dichromic acid.

Properties.—Potassium dichromate crystallizes in large orange-red transparent triclinic prisms or 4-sided plates, which are inodorous and are not altered on exposure. The salt melts below a red heat to a transparent dark brown-red liquid, which, on cooling, crystallizes and finally falls into a crystalline powder. At a white heat the salt is decomposed into oxygen gas, green chromic oxide, and yellow potassium chromate. The dichromate is insoluble in alcohol; it is soluble in water, 1 part of the salt requiring

at 0°	10°	20°	40°	60°	80°	100° C.
20.14	11.81	7.65	3.43	1.98	1.37	0.98 parts of water (Kremers).

The U. S. and P. G. give the solubility in water at 25° C. (77° F.) as 1 in 9 and as 1 in 1.5 parts of boiling water. The solution has an orange-red color, an acid reaction, and a bitter, styptic, metallic taste, and is deoxidized, with the formation of chromic oxide or chromic salts, on the addition of hydrogen sulphide, sulphurous acid, or of sulphuric acid and alcohol, or other organic matters. Heated with hydrochloric acid, chlorine is given off. The solution yields a pale-yellow precipitate with barium chloride, a yellow one with lead acetate, and a purplish-red one with silver nitrate, the three precipitates being soluble in nitric acid. With a cold saturated solution of sodium bitartrate a white crystalline precipitate of potassium bitartrate is produced, and sodium cobaltic nitrite produces a copious yellow precipitate.

Tests.—As met with in commerce, the salt is usually pure. Its solution in 100 parts of water should not be precipitated on the addition of excess of potassium carbonate (absence of calcium salt), and after having been acidulated with nitric acid should not be disturbed by barium chloride (absence of sulphates) or by silver nitrate (chlorides).

Composition and Uses.—The salt is free from water, and represents 31.86 per cent. of K_2O and 68.14 per cent. of CrO_3; it may be regarded as a compound of chromic anhydride with potassium chromate $= K_2CrO_4.CrO_3$, or as the neutral salt of *dichromic acid*, $H_2Cr_2O_7$, which is not known in the uncombined state. The chief use for the salt is as an oxidizer when mixed with sulphuric or acetic acid in chemical industries, particularly in the oxidation of anthracene to anthraquinone, from which alizarine is manufactured. Large quantities are also used for rapid tanning, which has been introduced in late years. It is used also in certain kinds of electric cells.

Action and Uses.—Potassium dichromate is a caustic like chromic acid, possessing, however, a milder action than the latter drug. A saturated aqueous solution affords a useful application for the removal of warts and syphilitic vegetations. Weaker solutions, containing 2 to 5 grains (0.10–0.30 Gm.) to the ounce (30 Cc.) of a mixture of glycerin and water, has been applied with asserted good results as an astringent in ulcerated sore throat. In large quantity potassium dichromate is a violent corrosive poison, producing severe abdominal pain, vomiting, purging, frequent bloody stools, general depression, coma, and death. Poisoning from the drug should be treated with lime-water, emetics, demulcent drinks, opium for the pain and gastro-enteritis, and stimulants like strychnine hypodermically for the depression. Its internal administration in secondary syphilis, progressive spinal paralysis, and other diseases is no longer in favor.

Potassii Chromas.—*Potassium chromate, Yellow or neutral chromate of potassium.* K_2CrO_4. Molecular weight, 192.94.—It is obtained by adding potassium carbonate to a hot solution of the dichromate as long as effervescence is observed; the solution changes in color to yellow, and yields on evaporation 6-sided lemon-yellow crystals, which may be fused without decomposition and dissolve in less than 2 parts of water, the solution having an alkaline reaction. It is employed as a reagent.

POTASSII ET SODII TARTRAS, *U. S.*—Potassium and Sodium Tartrate.

Soda tartarata, Br.; *Sodæ et potassæ tartras, Sodæ potassio-tartras, Tartarus natronatus*, P. G.; *Natro-kali tartaricum, Sal polychrestum Seignetti, Rochelle Salt, Tartrated soda*, E.; *Sel de Seignette, Soude tartarisée*, Fr.; *Seignettesalz*, G.

Formula, $KNaC_4H_4O_6 + 4H_2O$. Molecular weight, 280.18.

Potassium and sodium tartrate should contain not less than 99 per cent. of the pure salt.—U. S.

Preparation.—This double salt was first obtained in 1672 by Pierre Seignette, an apothecary of Rochelle, in France, and was sold as a secret remedy. But in 1731 the process for obtaining it was communicated by Boulduc to the French Academy, and by C. J. Geoffroy to Sloane, of London. It may be prepared by exactly neutralizing a solution of sodium carbonate with potassium bitartrate, boiling to drive out carbon dioxide, neutralizing again with the one or the other constituent if necessary, filtering, and evaporating to crystallization. The reaction is: $2KHC_4H_4O_6 + Na_2CO_3.10H_2O = 2KNaC_4H_4O_6 + CO_2 + 11H_2O$, a double tartrate being formed. 16 parts of potassium bitartrate require $12\frac{1}{6}$ parts of crystallized sodium carbonate if both are chemically pure. Owing to the presence of calcium tartrate in the one, and the loss of water of crystallization in the other, the proportions required must vary somewhat with different samples of the commercial salts; but there is no difficulty in rendering the solution exactly neutral

if the above directions are followed. It is advisable to keep the neutralized mixture for some time at a temperature of about 60° C. (140° F.), when much of the calcium tartrate will be deposited, and may be removed by filtration. Large and well-formed crystals are obtained if the solution is very slowly evaporated.

Properties.—Potassium and sodium tartrate crystallizes in large, perfectly transparent, inodorous, 6- or 8-sided prisms, or more frequently half-prisms, of the right rhombic order. If crystallized from a solution containing calcium tartrate, they are white and more or less opaque. In our commerce the salt is most generally met with in the state of white powder. It has a mild saline, faintly bitterish and cooling taste, is slightly efflorescent in dry air, and dissolves at 25° C. (77° F.) in 1.2 parts of water, and in less than 1 part of boiling, but is nearly insoluble in alcohol.—U. S. The salt melts in its water of crystallization when carefully heated to about 75° C. (167° F.), and after cooling remains liquid and soft for some time. By the heat of the water-bath it loses 19 per cent. of water of crystallization, and at 130° C. (266° F.), or, according to Fresenius, near 215° C. (419° F.), altogether 25.5 per cent. At a higher heat it is decomposed, gives off inflammable gases which have the odor of burning sugar, and leaves charcoal, mixed with the potassium and sodium carbonates, and imparts to a non-luminous flame a yellow color, appearing red when viewed through a blue glass. The concentrated aqueous solution yields, on the addition of hydrochloric or acetic acid, a crystalline precipitate of cream of tartar; with barium chloride, a white precipitate soluble in nitric acid; and with silver nitrate, a white precipitate turning black on boiling. The aqueous solution is feebly alkaline to litmus paper, but does not affect phenolphthalein.

Tests.—The solution in 20 parts of distilled water should be clear, of neutral reaction to test-paper, and should produce no precipitate or turbidity with ammonium oxalate (calcium salt) or with hydrogen sulphide (metals); and when acidulated with nitric acid and filtered from the precipitated acid potassium tartrate, the clear solution should not be affected by barium chloride (sulphate). The U. S. P., 1900, omits the tests for calcium, and for chloride and sulphate, but the P. G. demands the absence of these. Although ammonia is not likely to be present in a salt having the above properties, the U. S. and P. G. direct testing for it with caustic alkali. The aqueous solution (1 in 20) of the salt, slightly acidulated with hydrochloric acid, when mixed with an equal volume of hydrogen sulphide test-solution, should not give a precipitate or coloration, after standing corked in a warm place for at least half an hour, either before or after adding ammonia-water to slight alkalinity (absence of heavy metals). If 1 Gm. of potassium and sodium tartrate be thoroughly ignited at red heat, and the residue extracted repeatedly with hot distilled water, the united filtrates should require for complete neutralization not less than 14.1 Cc. of half-normal hydrochloric acid solution, methyl-orange being used as indicator.—U. S. Each Cc. of the acid represents 0.070045 Gm. of the salt, hence 14.1 Cc. represent 0.9876 Gm., which is 98.76 per cent. The Br. permits a salt of 98.05 per cent., 1 Gm. when titrated requiring at least 7 Cc. of normal acid.

Ammonii et Potassii Tartras. *Tartarus solubilis ammoniatus.—Potassium and ammonium tartrate*, E.; *Tartrate de potasse et d'ammoniaque*, Fr.; *Weinsaures Ammoniak-Kali*, G. $KNH_4C_4H_4O_6$.—It is prepared by diffusing 1 part of cream of tartar in 2½ or 3 parts of boiling water, adding ammonium carbonate as long as effervescence takes place, filtering, and crystallizing. It is well to render the solution alkaline by the addition of a little ammonia-water. The double salt crystallizes in transparent prisms having a pungent and cooling saline taste and becoming opaque on exposure from loss of ammonia. It is soluble in about 2 parts of cold and less than its own weight of hot water.

Action and Uses.—Rochelle salt, in doses of from 2 to 4 drachms (8–16 Gm.), is a mild laxative, more readily borne by the stomach than most salines. In larger quantity (1 ounce (30 Gm.) or more) it is an active hydragogue purge. It is the purgative constituent of Seidlitz powder (Pulvis Effervescens Compositus).

In small doses, frequently repeated, it does not purge, but is absorbed, probably as a carbonate, and renders the urine alkaline.

POTASSII FERROCYANIDUM, *U. S.*—Potassium Ferrocyanide.

Potassæ prussias flava, Kalium ferrocyanatum, Kalium borussicum.—Yellow prussiate of potash, E.; *Prussiate jaune de potasse, Ferrocyanure de potassium*, Fr.; *Ferrocyankalium, Blutlaugensalz*, G.

Formula, $K_4Fe(CN)_6 + 3H_2O$. Molecular weight, 419.62.

Potassium ferrocyanide should contain not less than 99 per cent. of the pure salt, and be kept in well-closed bottles.—U. S.

Preparation.—This salt was discovered by Macquer (1752) in boiling Prussian blue with potassium hydroxide. The iron contained in it was for a long time supposed to be an impurity, even after Berthollet (1787) had shown it to be one of its essential constituents. Yellow prussiate of potash, as it is commercially called, possesses no medicinal properties, but is the source of official hydrocyanic acid and other cyanides; when pure the salt is not poisonous. It is made by heating, in iron vessels, with constant stirring, a mixture of potassium carbonate, metallic iron, and scraps of horn, leather, or other nitrogen-containing substances. The fused mass, known as "melt," is, after cooling, leached with water, and the solution decanted and crystallized; the insoluble residue consists of iron, charcoal, ferrous sulphide, calcium phosphate, and silica.

While formerly the salt was made almost exclusively by this process, the source of the salt at the present time is the exhausted mass of ferric hydroxide which is used to purify illuminating-gas. Cyanogen compounds, as well as others, are absorbed by the iron hydroxide, by which, among other products, ferrocyanides are formed. By suitable chemical treatment the latter are converted into the potassium salt.

Properties.—Potassium ferrocyanide crystallizes from water in large inodorous, lemon-yellow, 4-sided tables or prisms, which are translucent and rather soft and friable, and, being crystallized on a cord, usually cohere in columnar masses. It has the specific gravity 1.83, a sweetish and saline taste, and dissolves with a yellow color in 4 parts of water at 25° C. (77° F.) and in 2 parts of hot water, the salt being precipitated from this solution by alcohol in pale-yellow pearly scales. The salt is permanent at a low temperature, but near 60° C. (140° F.) it begins to lose water of crystallization, of which it contains 12.8 per cent., and it becomes anhydrous at 100° C. (212° F.), leaving a white friable mass which melts below red heat, and at a higher temperature is decomposed into nitrogen and a mixture of potassium cyanide and carbide of iron. Exposed to light in the presence of moisture, it is slowly decomposed, with the formation of Prussian blue. Its solution has a neutral reaction and produces a dark-blue precipitate with ferric salts, a bluish-white precipitate (becoming dark-blue in contact with air) with ferrous salts; a brown-red precipitate with salts of copper; and white precipitates with lead acetate and mercuric chloride; also a white crystalline precipitate with a saturated solution of sodium bitartrate. Heated with dilute sulphuric acid, hydrocyanic acid is given off. Alkalies fail to precipitate the iron from its solution, but on fusing the salt with potassium carbonate, potassium cyanide is formed and metallic iron is separated.

Tests.—The concentrated solution of the salt should not effervesce on the addition of sulphuric acid (absence of carbonate). The precipitate produced in the aqueous solution, acidulated with nitric acid, by silver nitrate test-solution should be of a pure white color, without a tinge of red (absence of ferricyanide).—U. S. The tests for limit of chloride and sulphate have been dropped from the 1900 Pharmacopœia.

Pharmaceutical Uses.—Potassium ferrocyanide is used in the preparation of dilute hydrocyanic acid, of cyanides, ferrocyanides, and of the following salts:

Derivative Products.—Potassium Ferricyanide or Ferridcyanide. *Red prussiate of potash.* $K_6Fe_2(CN)_{12}$ or $K_3Fe(CN)_6$.—On passing chlorine gas into a cold solution of potassium ferrocyanide the liquid changes in color from yellow to red. When it ceases to produce a blue precipitate or color with ferric chloride, it is concentrated and the crystals purified by recrystallization. The salt is in dark-red transparent prisms, has a saline and slightly astringent taste, and dissolves in about 4 parts of cold water. On exposure to light the solution is readily altered, ferrocyanide being again produced, when it will yield a blue precipitate with ferric salt. The salt in its fresh solution is employed as a test, precipitating dark blue with ferrous, red brown with mercurous, brownish yellow with cupric, and orange colored with argentic salts. It yields no precipitates with ferric, mercuric, or plumbic salts.

Potassium Sulphocyanate (Sulphocyanide).—*Sulfocyanure de potassium*, Fr.; *Kaliumsulfocyanat, Rhodankalium*, G. Formula, KSCN. Molecular weight, 96.53.—It is prepared by melting together 17 parts of potassium carbonate, 32 parts of sulphur, and 46 parts of

anhydrous potassium ferrocyanide, and heating to low redness; the cold mass is treated with boiling alcohol. The salt crystallizes in colorless, 4-sided, striated prisms, which are inodorous, have a pungent and saline taste, are deliquescent on exposure, and dissolve readily in water and in alcohol. A solution of the salt is used as a test for ferric salts, with which it gives a blood-red color which is not discharged by hydrochloric acid (difference from acetates and formates), but disappears on the addition of corrosive sublimate (difference from meconates).

Sodium Nitroprusside. $Na_2Fe(CN)_5NO.2H_2O$.—It is prepared by digesting 1 part of potassium ferrocyanide with 2 parts of nitric acid and 2 parts of water until the liquid ceases to produce a blue precipitate with iron salts. On cooling, potassium nitrate crystallizes, and the mother-liquor after neutralization with sodium carbonate yields colorless crystals of potassium nitrate and red ones of sodium nitroprusside; the latter are recrystallized from water. The salt forms ruby-colored rhombic prisms which are permanent in the air and dissolve in 2½ parts of cold water, the solution being decomposed by light. A fragment of the salt heated with an oxygenated volatile oil darkens the latter, often producing a characteristic color; this reaction is prevented by oil of turpentine. In alkaline solution it is a delicate test for sulphides, producing with them a violet or blue color.

Action and Uses.—Potassium ferrocyanide is not used in internal medicine, except as a chemical antidote to poisoning by copper sulphate. Except in its impure commercial state it can be ingested in large quantity without producing any effect, either beneficial or deleterious, upon the economy.

POTASSII HYDROXIDUM, *U. S.*—Potassium Hydroxide.

Potassa, U. S., 1890.—*Potassa caustica*, Br.; *Kali causticum fusum*, P. G.; *Potassii (Potassæ) hydras, Kali hydricum fusum, Lapis causticus chirurgorum.*—*Caustic potash, Potassa, Potassium hydrate*, E.; *Potasse caustique, Potasse fondue, Pierre à cautère*, Fr.; *Kaliumhydroxyd, Ætzkali*, G.

Formula, KOH. Molecular weight, 55.74.

Potassium hydroxide should contain not less than 85 per cent. of pure potassium hydroxide and not more than 2 per cent. of foreign inorganic substances other than water. It should be kept in well-stoppered bottles of hard glass.—U. S.

Preparation.—The substance usually employed in pharmacy and the arts is obtained by the action of slaked lime on potassium carbonate, as described under Liquor Potassii Hydroxidi: $K_2CO_3 + Ca(OH)_2 = CaCO_3 + 2KOH$. The solution is evaporated rapidly in a clean silver or iron basin until the water is driven off and the potassium hydroxide remains in quiet fusion, when it is poured into iron or silver cylindrical molds to harden. The purity of the product depends upon the quality of the potassium carbonate used, and if made from the bicarbonate it is of much better quality. It is known in commerce as *potassa by lime*, and should contain not more than 5 to 6 per cent. of water, but it sometimes contains as much as 20 to 25 per cent. It is not advisable to try to drive off all the water by heating, as the iron or silver vessel is then attacked by the alkali. It should be preserved in glass-stoppered bottles of hard glass, with a layer of paraffin around the stopper to keep out moisture. White glass is attacked by the hydroxide, but green bottles serve very well for preserving it.

For chemical operations a purer article is often required, which may be obtained in several ways. *Potassa by baryta* is prepared by exactly precipitating a hot solution of crystallized barium hydroxide with a concentrated solution of potassium sulphate, filtering off the precipitate, and quickly evaporating as above: $Ba(OH)_2 + K_2SO_4 = BaSO_4 + 2KOH$. This method yields very pure potassium hydroxide.

Potassa by alcohol is prepared by dissolving 1 part of ordinary potassium hydroxide in 4 parts of 95 per cent. alcohol. After several days an aqueous layer collects at the bottom of the vessel containing the impurities, such as carbonate, chloride, sulphate of potassium, etc., while the alcoholic solution of pure potassium hydroxide stands above it, which may be drawn off and evaporated.

The purest potassium hydroxide is obtained by adding pure metallic potassium in small pieces to distilled water in a silver basin and evaporating as above: $K + H_2O = KOH + H$. Potassium hydroxide obtained by these three methods is much more expensive than potassium hydroxide by lime.

In recent years large quantities of caustic potash are made electrolytically from potassium chloride. When a strong electric current is passed through a solution of the

chloride in a suitable vessel, the chloride is decomposed into chlorine, which is collected at the positive electrode and used for making bleaching-powder, and potassium, which combines with water to form the hydroxide and accumulates at the negative electrode. The solution of potassium hydroxide is drawn off and utilized as such or evaporated.

Molten potassium chloride is also decomposed by the electric current, giving chlorine and metallic potassium, which is converted in the apparatus into solid potassium hydroxide by a jet of steam (*Elect. World and Eng.*, April 5, 1902).

Properties.—Caustic potash is either pulverulent or in irregular pieces of crystalline texture; more generally it is in dry white cylindrical pieces, which break readily with a crystalline and somewhat translucent fracture. It is inodorous or has a faint odor of lye; its taste is strongly caustic and acridly alkaline. It dissolves at 25° C. (77° F.) in 0.4 part of water and in 2 parts of alcohol, and is much more soluble in both liquids at the boiling temperature (U. S.); the taste and reactions of these solutions are strongly alkaline. The alcoholic solution is yellowish, and on keeping turns brown because of the aldehyde in the alcohol being converted into aldehyde resin. Alcohol which has been distilled several times from lime will remain colorless a long time when caustic potash is dissolved in it, being free from aldehyde. Potassium hydroxide is but slightly soluble in ether. On exposure to the air it rapidly absorbs moisture, liquefies, and combines with carbon dioxide. When heated to about 530° C. (986° F.) it fuses to a colorless oily liquid, and in a strong red heat it slowly volatilizes, forming white acrid vapors.

Tests.—The aqueous solution (1 in 20) should be perfectly clear and colorless (absence of organic matter). After acidulation with hydrochloric acid it yields a bright-yellow precipitate with platinic chloride test-solution. A concentrated aqueous solution (1 in 10), when dropped into tartaric acid test-solution, produces at first a white crystalline precipitate, which redissolves when the alkali is added in excess. The aqueous solution (1 in 20), slightly acidulated with hydrochloric acid, and mixed with an equal volume of hydrogen sulphide test-solution, should not give a precipitate or coloration after standing corked in a warm place for at least ½ hour, either before or after addition of ammonia to slight alkalinity (absence of heavy metals). On adding an excess of diluted sulphuric acid to 10 Cc. of a 10 per cent. aqueous solution of potassium hydroxide, no distinct effervescence should occur (limit of carbonate). The tests for absence of calcium and for limits of chloride, sulphate, silicate, and nitrate have been dropped from the 1900 Pharmacopœia, since these impurities are innocuous and the use of potassium hydroxide is more technical than medicinal. The P. G. retains the tests for the above impurities, but the Br. P. has a test for only silica and other insoluble matter in alcohol in addition to the hydrogen sulphide test for heavy metals. To test for sodium, dissolve 0.56 Gm. of potassium hydroxide in 5 Cc. of water, add a few drops of phenolphthalein test-solution, and then from a burette sufficient tartaric acid test-solution (3 Gm. in 20 Cc.) to neutralize the solution accurately. Next add another volume of the tartaric acid test-solution equal to that first used, and then sufficient absolute alcohol to precipitate completely the potassium bitartrate formed. Separate the precipitate by filtration and wash it with a little alcohol. The filtrate should not require more than 2 Cc. of tenth-normal potassium hydroxide solution to restore the red color (absence of more than 1.5 per cent. of sodium hydroxide). About 1 Gm. of the hydroxide, accurately weighed in a stoppered bottle, is dissolved in about 50 Cc. of water and titrated with normal sulphuric acid, using methyl-orange as indicator; multiply the number of Cc. of acid consumed by 5.574, and divide the product by the weight of hydroxide taken; the quotient, which must not be less than 85, is the per cent. of pure potassium hydroxide present.—U. S. Each Cc. of normal acid represents 0.05574 Gm. of KOH. The last test is not strictly accurate unless the total absence of sodium hydroxide is ascertained. The Br. P. and P. G. require 90 per cent. purity.

An impure potassium hydroxide of a deep-gray or greenish color is sometimes met with. It is unfit for medicinal purposes, and may be purified by treating it with alcohol, which dissolves the alkali, and evaporating this solution to dryness.

Potassa cum Calce. *Potassa with lime, Vienna caustic,* E.; *Caustique (Poudre) de Vienne,* Fr.; *Wiener Aetzpulver,* G.—This preparation is a grayish-white powder of a strongly caustic taste and alkaline reaction, obtained by rubbing together equal parts of caustic potash and lime in a warm mortar. When exposed to the air, it absorbs moisture and carbon dioxide. Treated with diluted nitric or hydrochloric acid, it dis-

solves completely with slight effervescence, and yields a solution in which both potassium and calcium are indicated by reagents.

CAUSTICUM CUM POTASSA ET CALCE, Fr. Cod., is a stronger preparation, known in France as *caustique de Filhos*, and made by fusing 100 parts of caustic potash, adding thereto 10 parts of powdered burned lime, and pouring the mass into lead tubes of suitable size to harden.

Action and Uses.—Potassium hydroxide is a violent, deeply penetrating caustic. It destroys the tissues for a considerable area around the point of application by abstracting water from them and decomposing nitrogenous compounds. Its application is attended by severe burning pain, and for this reason its use as a cauterant is greatly restricted. Taken in poisonous quantity it produces an alkaline taste in the mouth, intense burning pain in the fauces, œsophagus, stomach, and intestines; vomiting, usually of blood, purging, overwhelming oppression, sometimes convulsions, delirium, and death. If death does not occur promptly the patient may ultimately succumb to œdema of the larynx, widespread gastro-intestinal lesions, or to stricture of the œsophagus. The antidotes are vinegar, lemon-juice, or some other dilute acids or fixed oils. Potassium hydroxide may be used as a cauterant to growths, fungous granulations, and superficial cancers. When used, the skin surrounding its point of application should be protected by wax, suet, oils, or a piece of adhesive plaster with a hole in it large enough to admit the growth, to prevent extensive destruction of adjacent healthy tissue. When the caustic has acted sufficiently, it should be washed off with water, vinegar, or other dilute acid. In solution (Liquor Potassii Hydroxidi) it may be administered to correct the pain and discomfort due to gastric hyperacidity.

It is not as good a remedy as the alkaline carbonates or citrates to render the urine alkaline and allay irritability of the bladder due to highly acid urine. It is mildly diuretic. The dose of the liquor potassii hydroxidi is from 10 to 60 minims (0.6–4 Cc.).

POTASSII HYPOPHOSPHIS, *U. S.*—Potassium Hypophosphite.

Kalium hypophosphorosum.—Hypophosphite de potasse, Fr.; *Kaliumhypophosphit, Unterphosphorigsaures Kali*, G.

Formula, KH_2PO_2. Molecular weight, 103.39.

Potassium hypophosphite should be kept in well-closed bottles and contain 98 per cent. of pure salt. Caution should be observed in handling, as explosion is liable to occur when triturated or heated with nitrates, chlorates, or other oxidizing agents.—U. S.

Preparation.—This salt may be prepared in a manner similar to that by which CALCIUM HYPOPHOSPHITE (which see) is obtained. When a solution of potassium hydroxide is boiled with phosphorus, potassium hypophosphite is produced, which is freed from alkali by passing carbon dioxide into the solution, evaporating, and dissolving the hypophosphite by alcohol. It is also yielded by the double decomposition of calcium hypophosphite and potassium carbonate, when calcium carbonate is precipitated and potassium hypophosphite remains in solution; $Ca(H_2PO_2)_2 + K_2CO_3$ yields $CaCO_3 + 2KH_2PO_2$.

Properties.—It may be obtained in hexagonal tabular crystals, but, being extremely deliquescent on exposure, it is usually seen in white, opaque, crystalline masses or as a white granular powder. It is inodorous, has a pungent, saline, and bitterish taste, and a neutral or faintly acid reaction. It dissolves in 0.5 part of water and in 7 parts of alcohol at 25° C. (77° F.), in 0.3 part of boiling water and in 3.6 parts of boiling alcohol, insoluble in ether.—U. S. Heated to redness when not in contact with air or in a long test-tube, it evolves easily inflammable hydrogen phosphide, burning with a white (bright-yellow, U. S.) flame. According to Remmelsberg (1872), the gas given off consists of hydrogen and hydrogen phosphide, and the residue of potassium pyrophosphate and metaphosphate. Heated in the air, the salt burns with a yellow flame, and when evaporated with nitric acid or triturated or heated with oxidizing agents it detonates violently. When boiled with potassium hydroxide, hydrogen is given off; phosphite and, after the solution becomes more concentrated, phosphate of potassium are formed. The solution yields with a saturated solution of sodium bitartrate a white crystalline precipitate of cream of tartar, and with silver nitrate a white precipitate which rapidly turns brown and black, separating metallic silver; acidulated with hydrochloric acid, and gradually added to a solution of corrosive sublimate, it causes a white precipitate consisting of calomel, and on further addition a black precipitate of metallic mercury.

Tests.—The aqueous solution of the salt (1 in 20) should not effervesce on the addition of an acid (absence of carbonate).—U. S. The aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, should not show the presence of heavy metals when treated with an equal volume of hydrogen sulphide solution, and kept corked in a warm place for at least ½ hour, neither before nor after addition of ammonia-water. 5 Cc. of a 10 per cent. solution, when evaporated to dryness on a water-bath with 3 Cc. of nitric acid in 10 Cc. of water, should not respond to the modified Gutzeit's test for arsenic (see under ARSENI TRIOXIDUM).

The U. S. P. (1900) has dropped the volumetric estimation of this salt by permanganate solution. This method is defective, as are the other titration methods, and the only accurate estimation is by the gravimetric method (see under CALCII HYPOPHOSPHIS). The tests for chloride, sulphate, and phosphate have also been omitted.

Action and Uses.—Potassium hypophosphite is used for the same purposes and in the same dose as CALCII HYPOPHOSPHIS (which see).

POTASSII IODIDUM, *U. S., Br.*—Potassium Iodide.

Kalium jodatum, P. G.; *Kali hydroiodicum, Iodure de potassium*, Fr.; *Jodkalium*, G.

Formula, KI. Molecular weight, 164.76.

Potassium iodide should be kept in well-stoppered bottles and contain not less than 99 per cent. of pure salt.—U. S.

Preparation.—No detailed methods are given in the U. S., Br. P., or P. G. This salt is prepared by methods exactly like those given under POTASSII BROMIDUM (which see). When iodine is added to a solution of potassium hydroxide, potassium iodide and iodate are formed: $6KOH + 6I = 5KI + KIO_3 + 3H_2O$. After evaporation the mass is mixed with charcoal, dried, and heated to redness, whereby the iodate is reduced to iodide.

The salt may also be obtained by interaction between ferrous iodide and potassium carbonate as described under POTASSIUM BROMIDE. A source for large quantities of potassium iodide is cuprous iodide, which is manufactured as a by-product from sodium iodate obtained from the mother liquors of Chille saltpeter (see IODINE). The copper iodide is suspended in water acidified with hydrochloric acid, and decomposed by hydrogen sulphide, forming insoluble copper sulphide and hydriodic acid. The latter is neutralized with potassium carbonate and evaporated to crystallization.

Nearly all the potassium iodide consumed here is now manufactured in the United States.

Properties.—Potassium iodide is in colorless transparent or translucent or white cubes of a neutral or scarcely perceptible alkaline reaction upon litmus-paper. Potassium iodide has a peculiar, faint, iodine-like odor, a pungent, saline, afterward bitterish taste, melts below a red heat, and congeals on cooling to a pearly mass. On melting the salt in contact with air a trace of iodate is formed, a little iodine given off, and the mass acquires an alkaline reaction (Petterson, 1870); at a bright-red heat the salt is slowly volatilized. It is permanent in the air, but in a damp atmosphere or when of an alkaline reaction is somewhat deliquescent. It is freely soluble in water, requiring, at ordinary temperature, 0.75 part and 0.5 part of boiling water. It is also soluble in alcohol, requiring 12 parts (U. S.) at 25° C. (77° F.) and 6 parts of boiling alcohol; also soluble in 2.5 parts of glycerin. Rapid solution of the salt in water produces a marked fall in temperature. The aqueous solution yields with tartaric acid or with sodium bitartrate a white crystalline precipitate of potassium bitartrate, and with a few drops of chlorine water liberates iodine, which is recognized by the blue color it imparts to starch-paste or by the violet color of its solution in chloroform or carbon disulphide. On exposure to sunlight solutions of potassium iodide acquire a yellow or brownish color from the liberation of iodine. The experiments of Papasogli (1881) prove that sunlight, both diffused and direct, does not decompose pure potassium iodide or its mixture with iodate; but carbonic anhydride liberates from the mixture a small quantity of iodine, while at low temperatures it has no effect upon either one of the pure salts, yet at high temperatures separates hydriodic acid in solutions of the pure iodide. Strong mineral acids, such as concentrated nitric and sulphuric, liberate iodine from the dry salt or its solution. Ferric salts, platinum chloride, nitrous acid, chlorine, and bromine also liberate iodine in solutions of the iodide. A mixture of the salt with ammonium chloride

becomes moist and brown on exposure, and when heated is decomposed, potassium chloride and iodide being left. In concentrated solution 1 molecule of potassium iodide dissolves 2 atoms of iodine, forming $KI.I_2$, which is decomposed on dilution with water, precipitating a portion of the iodine. If the molecular weight of the salt is dissolved in about 30 times its weight of water, the solution takes up 1 atomic weight of iodine. These solutions are completely decolorized when agitated with ether, chloroform, or carbon disulphide; but if the solution has been made with alcohol instead of water, carbon disulphide fails to extract the iodine, although this element is removed by the solvent mentioned from the simple tincture of iodine (Jörgensen, 1870). These facts, it seems, point to the existence of compounds of 1 atom of potassium with 1, 2, and 3 atoms of iodine.

Tests.—If impurities other than bromide and chloride are present, the large cubical crystals will usually be the purest; for the following tests it is therefore advisable to triturate together crystals of different size. A little of the powdered salt taken up with the loop of a platinum wire and held in a non-luminous flame should at once impart a violet color to the latter (absence of sodium salt).—P. G. No residue should be left when 1 Gm. of the salt is dissolved in 2 Cc. of diluted alcohol of specific gravity 0.928 (absence of less soluble salts). If 1 Gm. of the salt be dissolved in 10 Cc. of water and 0.1 Cc. (2 drops) of tenth-normal sulphuric acid solution be added, no color should be produced by the subsequent addition of a drop of phenolphthalein test-solution, even after heating (limit of alkali). This test shows the absence of more than 0.07 per cent. of carbonate. The aqueous solution (1 in 20) slightly acidulated with hydrochloric acid should not be colored or precipitated by the addition of an equal volume of hydrogen sulphide test-solution, after standing corked in a warm place for at least ½ hour, either before or after addition of ammonia-water to slight alkalinity (absence of arsenic, lead, copper, etc.). 10 Cc. of a 5 per cent. solution, when acidulated with hydrochloric acid, should not be rendered turbid by the addition of 1 Cc. of potassium sulphate test-solution (absence of barium). If 1 Gm. of the salt, 5 Cc. of water, 5 Cc. of potassium hydroxide test-solution, and about 0.2 Gm. of aluminum wire be heated for 15 minutes on a water-bath in a tube containing a pledget of purified cotton in the upper portion and covered with a moistened piece of red litmus-paper, no blue coloration of the paper should be visible (limit of nitrate or nitrite). No blue color should be communicated to 20 Cc. of the aqueous solution (1 in 20) by 0.5 Cc. (10 drops) of potassium ferrocyanide test-solution (absence of iron).—P. G. If to 0.5 Gm. of the salt dissolved in 10 Cc. of previously boiled and cooled distilled water, 2 drops of diluted sulphuric acid (free from sulphurous and nitrous acids) be added, no distinct yellow color should appear within ½ minute (limit of iodate). Cyanide may be present from using impure potassium carbonate or impure iodine; its presence is determined by adding to a solution of the iodide a little ferrous sulphate, a drop of solution of ferric chloride or sulphate, and a slight excess of solution of sodium hydroxide. On warming the mixture and acidulating it with hydrochloric acid a blue color (of Prussian blue) should not be produced. 0.2 Gm. of the salt dissolved in 2 Cc. of ammonia-water, and then agitated with 13 Cc. of tenth-normal solution of silver nitrate, should yield a filtrate which on being acidulated with nitric acid should not become more than slightly turbid nor should any darkening appear within 10 minutes (limit of chlorides or bromides and absence of thiosulphate), U. S.; or should not become so turbid within 10 minutes as to lose its pellucidity.—P. G. This test proves the absence of more than about 1 per cent. of chloride and bromide. Silver iodide is also slightly soluble in (about 3000 parts of) ammonia-water. If 0.5 Gm. of the well-dried salt be dissolved in 10 Cc. of distilled water with 3 drops of potassium chromate test-solution as indicator, it should require not more than 30.8 Cc. nor less than 30 Cc. of tenth-normal silver nitrate solution to produce a permanent red color (corresponding to at least 99 per cent. of pure salt).—U. S. The theoretical quantity of silver solution required for 0.5 Gm. of pure potassium iodide is 30.35 Cc. Each 0.372 Cc. of silver solution consumed in excess of the theoretical quantity represents 1 per cent. of potassium chloride, assuming this to be the impurity present. Hence an excess of 0.47 Cc. of silver solution allowed by the U. S. P. represents 1.2 per cent. of KCl in the salt. The lower limit, 30 Cc., is less than the theoretical quantity of silver solution, which may be due to impurities having no action on silver, and represents 98.51 per cent. of KI. 1 Cc. of the silver solution = 0.016476 Gm. of KI. According to the Br. P., 1 Gm. should require not less

than 59.5 Cc. nor more than 61.9 Cc. of tenth-normal solution of silver nitrate for titration. The theoretical quantity for the pure salt is 60.7 Cc. (British atomic weights); assuming the absence of chloride, the lower limit, 59.5 Cc., corresponds to 98 per cent. of KI, thus allowing 2 per cent. impurity other than chloride. This seems inconsistent with the demands of purity given in the Br. The upper limit of 61.9 Cc., assuming that the excess over the theoretical amount is due to chloride, allows 1.86 per cent. of chloride, which again is inconsistent with the demands in the tests for purity.

The results of the volumetric assay are subject to misinterpretation unless the operator is experienced, inasmuch as the method is based upon the assumed presence of alkali chloride, omitting the possibility of other haloid salts being present. Accurate estimation of the iodide as well as the bromide is best done by gravimetric methods, for which standard works on chemistry should be consulted.

Potassium carbonate, sulphate, iodate, nitrate, and cyanide are insoluble in strong alcohol, which dissolves only small quantities of potassium bromide and chloride. An adulteration of the iodide with more than mere traces of the last two salts may be detected by treating the iodide with 18 times its weight of warm alcohol, and, after cooling, testing the undissolved portion. These admixtures may be estimated from the silver precipitate, which from 10 grains of pure potassium iodide weighs 14.15 grains (or 1.415 Gm. from 1 Gm. of the salt), from the same quantity of bromide, 15.8 grains, from chloride 19.2 grains, and from cyanide 20.57 grains. Moreover, the last three may be extracted from the former by ammonia, and, after acidulating this solution with nitric acid, collected, and weighed separately; or, instead of dissolving it in water, the salt to be tested may be dissolved in ammonia-water, when, on the addition of silver nitrate, only silver iodide will be thrown down.

Action and Uses.—Iodide of potassium exercises a powerful influence upon nutritional and metabolic processes in the body. The somewhat indefinite term "alterative" is often applied to its activities. Potassium iodide is rapidly absorbed and rapidly eliminated, escaping from the body by all the secretions, but chiefly through the kidneys and salivary glands. Although the greater portion of it escapes in the first 24 hours, some of it remains in the body for days after the last dose has been taken; and if the administration of it has been continued for a long period, a considerable quantity accumulates in the body. For this reason larger doses are needed at first than later on, in the treatment of such diseases as syphilis, chronic rheumatism, and other conditions, in which full doses are often required. Small quantities slightly raise the blood-pressure, but full doses distinctly lower it, particularly if the pressure be high because of arteriosclerosis. It does not always act as a diuretic, but in certain cases of heart disease and renal disease it greatly increases the urinary flow. It is employed in medicine chiefly for the purpose of treating syphilis, particularly when this disease has advanced toward the end of its second stage or is entering upon its tertiary manifestations. It is also of value in the early portion of the second stage of the disease, but at this time does not give the results which can be obtained by the administration of the various preparations of mercury. In the treatment of syphilis with the iodide of potassium very much larger doses are used than are commonly given for other diseases. Cases are on record in which as much as 800 or 1000 grains have been taken in 24 hours, the patient arriving at these quantities at the end of a considerable period of time during which ascending doses have been given. It is customary to start with 5 to 10 drops of a saturated solution (1 grain to the drop) 3 times a day after meals, and to add 1 drop to each dose each day. The drug should be continued for a long period of time, not less than from 1 to 2 years, if there are manifestations of syphilis present. Indeed, it is often advantageous, in order to prevent the development of parasyphilitic conditions in later life, to continue the iodide of potassium in moderate doses, alternating with protoiodide of mercury, for 3 years.

Iodide of potassium is the best drug that we have for combating the advances of parasyphilitic conditions of the nervous system which develop years after the primary infection, but it is to be distinctly understood that the drug cannot cure those lesions of the nervous system which have resulted in sclerotic changes. The most it can do is to arrest the progress of degenerative processes, and so prevent any increase in the severity of the symptoms. When very active manifestations of syphilitic disease appear in the nervous system, the protoiodide of mercury is often the better drug, since mercury is a more rapidly acting syphilitic remedy than is iodide of potassium. Many specialists in

the treatment of syphilis use the protoiodide of mercury for several months, then employ the iodide of potassium for several months, and then return once more to the mercurial.

The second valuable employment of iodide of potassium is in the treatment of chronic metallic poisoning, particularly that which is due to lead, arsenic, or mercury. Under these circumstances it forms double soluble salts with the metals in the tissues and aids in their elimination. It is also of value in chronic articular and muscular rheumatism, but it is of little or no value in acute or inflammatory rheumatism, although in the later stages of this disease it may aid materially in causing absorption of the inflammatory exudates which have been produced by the acute stage. In all forms of chronic rheumatism it often acts best if combined with wine of colchicum root. Iodide of potassium also has a reputation of being of value in the treatment of certain forms of asthma and in catarrh of the stomach and bowels of the subacute type. It should not be used in bronchitis if the bronchial secretion is very profuse and liquid. For that practically incurable condition—pulmonary emphysema—iodide of potassium has been largely employed, but any relief that comes to the patient from its use is probably due to its effect upon the associated chronic bronchitis or its influence upon the heart, blood-vessels, and kidneys. The drug has also been used in the treatment of hepatic cirrhosis with asserted advantage.

A very useful employment of iodide of potassium is in the treatment of arteriosclerosis, whether this change in the vascular system be due to advancing years, syphilis, gout, metallic poisoning, or any of the other causes which are known to be provocative of this condition. Iodide of potassium is also advantageous in some cases of pleural and abdominal effusion for the purpose of aiding in the disappearance of the liquid.

When iodide of potassium is taken in full dose, particularly if the person is susceptible to its effects, it not rarely causes coryza, so that the patient seems to be suffering from a severe cold in the head. In other instances, with or without these symptoms, acne develops on the face, back, and chest, and, occasionally, those who have an idiosyncrasy to the drug have various aberrant rashes break out, varying in severity from that of a mild dermatitis to petechiæ, bullæ, or blebs. A few cases have been reported in which œdema of the glottis has followed its employment.

The manner in which iodide of potassium does good in all the conditions which have been named is not understood. It undoubtedly exercises an influence upon nutrition, but what these influences are our knowledge of physiology and pathology is not sufficient to give us light upon the subject.

As the taste of iodide of potassium is exceedingly disagreeable to many persons, it is best to order it in saturated solution, and to prescribe compound syrup of sarsaparilla in another bottle. The patient then places the required number of drops of the solution of iodide of potassium at each dose in a dessertspoonful or a tablespoonful of the compound syrup with the hope that the sarsaparilla may cover its taste. Other physicians administer the iodide with fluidextract of licorice, in milk, or in junket, the latter method of administration being very popular. The iodide, as a rule, should be given 1 hour after meals rather than immediately after. It should not be taken on an empty stomach when its systemic influence is desired. If the patient is unable to carry a solution of the drug because of its bulk, it may be put up in capsules or tablets, and each dose followed by a draught of milk or water, for the purpose of diluting the drug after it enters the stomach, otherwise it may produce gastric irritation.

For all conditions in which iodide of potassium has been suggested and recommended, save syphilis, the ordinary dose is from 5 to 20 grains (0.30–1.30 Gm.).

POTASSII NITRAS, *U. S.*, *Br.*—Potassium Nitrate.

Kalium nitricum, P. G.; *Potassæ nitras, Nitrum depuratum, Sal petræ, Sal nitri.*—*Nitrate of potash, Nitre, Saltpetre*, E.; *Azotate (Nitrate) de potasse, Nitre prismatique, Salpêtre*, Fr.; *Kaliumnitrat, Salpetersaures Kali, Salpeter, Kalisalpeter*, G.

Formula, KNO_3. Molecular weight, 100.43.

Potassium nitrate should contain not less than 99 per cent. of the pure salt.—U. S.

Origin and Preparation.—Nitrum of the Romans was alkali carbonate, that of sodium being chiefly thus designated. Saltpetre was known to Geber in the eighth century, and in the Latin translations of his writings is called sal petræ and sal petrosum. Subsequently it was distinguished as sal nitrum or sal nitri, until at the close of the sixteenth century it was called nitrum. (See Sodii Carbonas.) Fused by itself or with

the addition of a small quantity of sulphur, it was formerly used as *sal prunelle* or *nitrum tabulatum*. Saltpetre is produced near the surface of the earth wherever nitrogenous organic substances are undergoing decomposition in the presence of air, moisture, and potassium compounds. It is present in considerable quantities in the calcareous soil near dwellings of some parts of India. This soil becomes impregnated with urine, and after it has been exhausted of its soluble salts soon generates them again, the decomposition being hastened by the hot and moist climate. In several parts of Europe nitrates are formed in a precisely analogous manner, either by collecting the urine of domestic animals in ditches which have been previously filled with a porous calcareous earth, or by mixing in the so-called *saltpetre-beds* animal and vegetable substances with wood-ashes and marl or other material containing lime, and forming this mixture into mounds which are occasionally moistened with drainings from the dung-pit, until after two or three years the salt accumulates in the outer layer of the heap, which is then removed, lixiviated with water, and left in contact with wood-ashes in order to decompose the calcium and magnesium nitrates which are usually present. In India, which furnishes the greater part of the nitre, the process of exhausting the earth is very similar, except that it is usually packed upon wood-ashes and the whole lixiviated. The real cause of the formation of nitrates from nitrogenous matter is a nitrifying bacillus or ferment, *Bacillus nitrificans*. By the action of this germ the ammonia formed by the decay of organic matter is oxidized, first to nitrous, then to nitric acid, which, in contact with the alkalies in the soil, forms nitrates.

In the Mammoth Cave of Kentucky, and in other localities of the United States, saltpetre has occasionally been procured, and it may be obtained in variable quantities from most soils where vegetable and animal materials have been decaying, and from which it is taken up by the plants growing there, some of which are very rich in this salt. A. Boutin (1874) ascertained that *Amarantus melancholicus ruber* contains 16, and *Am. atropurpureus* even 22.77, per cent. of potassium nitrate, calculated for the dry herb. The same salt crystallizes in some old extracts.

At present potassium nitrate is made almost exclusively from potassium chloride of the Stassfurt mines by a process of mutual decomposition effected with native sodium nitrate (Chile saltpetre), advantage being taken of the lesser solubility of the newly formed sodium chloride in hot water to rid the solution of this impurity upon concentration by boiling. The potassium nitrate subsequently crystallizes out, and is further purified by recrystallization. On cooling the solutions the crystallization of the nitre is usually disturbed by frequent stirring in order better to drain off the mother-liquor, in which most of the foreign salts remain dissolved.

Most of the saltpetre used in the United States is purified here from the foreign crude article, of which more than 10,300,000 pounds were imported during the year 1900.

Potassium nitrate is to be had both in the form of large crystals and as a fine granular powder; the latter is preferred for pharmaceutical purposes, and is largely obtained from manufacturers of gunpowder, who require a pure article for their purposes.

The name saltpetre, or nitre, is used almost exclusively in commerce for this salt, and when fused and cast into round molds it is sold under the name *sal prunelle*.

Properties.—Potassium nitrate crystallizes in colorless, transparent, 6-sided, striated prisms of the rhombic system, which frequently have cavities in the interior filled with mother-liquor, so that on trituration they yield a damp powder. It is often kept in the granulated state, and is then a white crystalline powder. When heated to 353° C. (667.4° F.), it fuses to a colorless liquid, and congeals again on cooling to a radiating crystalline mass; in the presence of even a small proportion of sodium chloride the radiating arrangement is less distinct, at least in the centre of the mass, or entirely wanting. At a higher temperature it gives off oxygen, and afterward oxygen and nitrogen, being gradually converted into potassium nitrite and oxide; on the addition of sulphuric acid this residue gives off nitrous vapors. Potassium nitrate is neutral to test-paper, inodorous, has a pungently saline and cooling taste, and dissolves in water with a marked diminution of temperature. 1 part of the salt dissolves

at 0°	15°	30°	40°	50°	60°	80°	100°	114.1° C.	
in 7.25	3.85	2.25	1.563	1.163	0.901	0.582	0.405	0.306	parts of water,

the boiling-point of the most concentrated solution being 114.1° C. (237.4° F.). The salt is insoluble in absolute and sparingly soluble in diluted alcohol. It is permanent in

the air, but, according to Mulder (1864), absorbs a considerable amount of water when kept in a confined atmosphere saturated with moisture. When thrown upon red-hot coal it deflagrates. Warmed with sulphuric acid and copper it evolves red nitrous vapors; its aqueous solution gives a white crystalline precipitate of cream of tartar on the addition of a concentrated solution of tartaric acid or of sodium bitartrate, and if acidulated with hydrochloric acid yields a yellow precipitate with platinum chloride.

Tests.—The aqueous solution of the salt (1 in 20) should have a neutral reaction, and should not be affected by hydrogen sulphide or ammonium sulphide (absence of metals), barium chloride (absence of sulphate), silver nitrate (chloride), ammonium carbonate (calcium salt), or, after the addition of ammonium carbonate, by ammonium phosphate (magnesium salt). The U. S. P. (1900) has omitted all of these tests except that with hydrogen sulphide, but the Br. P. and P. G. still retain them. On mixing the powdered salt or its concentrated solution with alcohol, and igniting the latter, the flame should have a violet but not a yellow color (sodium salt). The aqueous solution (1 in 20) of the salt, slightly acidulated with hydrochloric acid, when mixed with an equal volume of hydrogen sulphide solution, should not give a precipitate or coloration, after standing corked in a warm place for at least half an hour, neither before nor after adding ammonia-water to alkalinity (absence of heavy metals). If a small crystal of ferrous sulphate or a drop of diphenylamine test-solution be mixed with the aqueous solution (1 in 20) and concentrated sulphuric acid be poured in, so as to form a separate layer, a dark-brown or a deep-blue color, respectively, will appear at the line of contact (nitrate). If to 10 Cc. of the aqueous solution (1 in 20) of the salt 1 Cc. of chloroform be added, then chlorine-water, diluted with an equal volume of water, drop by drop, with agitation, the chloroform should be free from any violet tint (iodine). No yellow color should appear when 0.1 Gm. of the dry salt is sprinkled upon 1 Cc. of pure concentrated sulphuric acid (absence of chlorate and perchlorate). On mixing 1 Gm. of the dry salt with 1 Gm. of sulphuric acid, evaporating to dryness, and igniting, the residue consists of potassium sulphate, and should weigh 0.86 Gm. In the presence of sodium nitrate the weight is less. The salt is an excellent oxidizing agent, as it parts easily with its oxygen at elevated temperature; with charcoal, sulphur, sugar, etc., it forms highly combustible or explosive mixtures.

Action and Uses.—In small doses potassium nitrate is diuretic and diaphoretic. Larger doses produce purgation and cardiac sedation, and if given over a long period of time cause irritation of the stomach, a slow weak pulse, and general depression. Poisonous quantities (½ ounce (16 Gm.) or more) produce severe gastro-enteritis, vomiting and purging of blood, suppression of urine, decided circulatory and respiratory depression, convulsions, and occasionally death, which may, however, occur suddenly unattended by any painful symptoms. At autopsy the stomach and intestines are found to be injected, the blood of a lighter color than normal, and the kidneys in a state of acute inflammation. There is no known chemical antidote to potassium nitrate, and poisoning is to be treated by removing the drug from the stomach and administering oils or mucilages, stimulants, and opium for the pain. Potassium nitrate is inferior as a diuretic to the harmless vegetable potassium salts, which have replaced it in the treatment of dropsy, rheumatism, and fevers. In spasmodic asthma, inhalation of the fumes of burning potassium nitrate allays the spasm and renders the breathing freer and less stridulous. For this purpose the Chartæ Potassii Nitratis are used, either by being rolled into cigarettes and smoked by the asthmatic or a piece of the paper is burned in a pan and the fumes inhaled. Impregnation of the paper with compound tincture of benzoin or tincture of belladonna in addition to the nitre enhances its efficiency. In the combustion of the drug potassium and ammonium nitrites, pyridine, and other bodies are formed, and to these the antispasmodic properties are ascribed. Nitre is sometimes used by packers to preserve meats. It is given in the dose of from 5 to 30 grains (0.3–2 Gm.).

POTASSII PERMANGANAS, *U. S.*, *Br.*—Potassium Permanganate.

Kalium permanganicum, P. G.; *Potassæ permanganas, Kali hypermanganicum crystallizatum.—Permanganate of potash*, E.; *Permanganate de potasse*, Fr.; *Kaliumpermanganat, Uebermangansaures Kali, Chamæleon*, G.

Formula, $KMnO_4$. Molecular weight, 156.98.

Potassium permanganate should be kept in glass-stoppered bottles protected from

light, and should not be triturated nor combined in solution with organic or readily oxidizable substances. It should contain not less than 99 per cent. of the pure salt.—U. S.

Preparation.—No method is given in the pharmacopœias. As stated under MANGANUM, a number of oxides of manganese exist, the lower ones being basic, while the higher ones, as MnO_3 and Mn_2O_7, are acidic, forming manganic and permanganic acids, respectively, H_2MnO_4 and $HMnO_4$. Manganic acid, however, does not exist in the free state, but only in its salts, the manganates, which are green. When oxygen is added to any of the lower oxides or their compounds in the presence of an alkali, manganate is formed, or if in acid solution, permanganic acid is obtained. Manganates are very unstable and easily form permanganates when their solutions are diluted and heated or acidified. In the manufacture of potassium permanganate the first step is the production of potassium manganate, by heating to semifusion at a dull-red heat an intimate mixture of manganese dioxide, caustic potash, and potassium chlorate, when the following reaction occurs: $3MnO_2 + 6KOH + KClO_3 = 3K_2MnO_4 + KCl + 3H_2O$. The green fused mass is then treated twice with boiling water, whereby the potassium manganate is converted into permanganate—$3K_2MnO_4 + 2H_2O = 2KMnO_4 + MnO_2 + 4KOH$—manganese dioxide being again precipitated and potassium hydroxide remaining in solution with the permanganate. The presence of potassium hydroxide in the liquid prevents a full yield of permanganate by holding a portion of the manganate in solution without change; a stream of carbon dioxide is therefore passed into the liquid to neutralize the potassium hydroxide and thus allow all the manganate to be converted into permanganate and dioxide; in place of carbon dioxide, diluted sulphuric acid is sometimes used for the same purpose. Finally, after decantation and filtration through asbestos, the solution is concentrated and set aside to crystallize. As potassium permanganate is readily decomposed by organic matter, all dust and dirt must be excluded during the last steps of the process, and filtration must not be performed through organic filters, as paper or muslin. The first crop or two of crystals are usually pure; subsequently they become mixed with potassium chloride and sulphate, and require to be purified by recrystallization. Finally, the other salts accumulate in the mother-liquors to such an extent that crystals of pure permanganate can no longer be obtained, and the liquids are advantageously used for disinfecting, bleaching, or other purposes.

The approximate quantities to be used in the above fusion are 5 parts of caustic potash, 4 parts of good (90 per cent. or over) manganese dioxide, and 3½ parts of potassium chlorate, the latter furnishing oxygen to the manganese dioxide. On account of the change of color from the green manganate to the purple permanganate, the former was formerly known as chameleon mineral.

Properties.—Potassium permanganate is in dark-purple or deep violet-red, nearly black, slender monoclinic prisms, which have a greenish or bluish metallic luster, do not react upon litmus-paper, are permanent in the air and without odor, and have a sweet, astringent taste. A small quantity of it imparts to a large quantity of water a rich purple tint, which is destroyed by organic matter and deoxidizing agents. Alcohol, acetone, acetic acid, oxalic acid, glycerin, tartaric acid, citric acid, sugar, gum, tannin, quinine, aniline, gelatin, and many other organic compounds are more or less readily oxidized in the cold or on boiling. It dissolves at 25° C. (77° F.) in 15 (20, Br.) parts of water and in 3 parts of boiling water. The solution of the pure salt may be boiled without being decomposed, but in the presence of much potassium hydroxide it acquires a green color from the formation of manganate, oxygen being given off at the same time; $2KMnO_4 + 2KOH$ yields $2K_2MnO_4 + H_2O + O$. A diluted solution of potassium hydroxide exerts no reducing action except in the presence of organic matter. The solution of permanganate is decolorized by hydrogen sulphide, carbon disulphide, thiosulphates, sulphites, phosphorus, hypophosphites, iodine, iodides, and many other inorganic oxidizable substances, as well as by organic compounds; the brown oxide which is precipitated yields with diluted sulphuric acid a colorless or reddish solution. When heated to redness, the salt parts with a portion of its oxygen and leaves a black residue of an alkaline reaction, from which water extracts potassium hydroxide. When thrown upon red-hot charcoal it deflagrates, and upon being triturated with sulphur or other inflammable bodies the mixture is decomposed with detonation. On mixing its solution in a closed vessel with glycerin, syrup, or other liquids containing organic matter a similar decomposition, accompanied by explosions, will take place. A warm concentrated solution of it, mixed with silver nitrate and allowed to cool, deposits large crystals of

silver permanganate, which require over 100 parts of water for solution and are decomposed on being boiled with water. The stains produced by potassium permanganate in mortars and other utensils may be speedily removed by a strong solution of oxalic acid.

Tests.—The solution of the salt in much water should have a rose color, without a tinge of green (absence of manganate). If 0.5 Gm. of the salt be boiled with 20 Cc. of water and 4 Cc. of alcohol until it is completely decomposed, and the liquid then filtered, the clear, colorless filtrate will serve for the following tests: 5 Cc. of the filtrate, acidulated with nitric acid, should not be rendered more than very slightly turbid by the addition of barium chloride test-solution (limit of sulphate). In another portion of 5 Cc., acidulated with nitric acid, silver nitrate test-solution should produce no precipitate or cloudiness (absence of chloride). If to another portion of 5 Cc. of the filtrate 1 drop of diphenylamine test-solution be added, and then 1 Cc. of pure concentrated sulphuric acid be poured in, so as to form a layer beneath, no blue color should appear at the line of contact (absence of nitrate). If 0.1 Gm. of the salt be dissolved in 100 Cc. of hot distilled water, to which 1 Cc. of pure sulphuric acid had previously been added, the solution should require for complete decoloration not less than 31.5 Cc. of tenth-normal oxalic acid solution.—U. S.

The official test with oxalic acid depends upon the following reaction: $2KMnO_4 + 5H_2C_2O_4.2H_2O + 3H_2SO_4 = 10CO_2 + K_2SO_4 + 2MnSO_4 + 13H_2O$; which shows that 313.96 parts of potassium permanganate are capable of oxidizing 625.5 parts of crystallized oxalic acid. As each Cc. of tenth-normal oxalic acid solution contains 0.006255 Gm. of the acid, it will require 0.0031396 Gm. of potassium permanganate for oxidation: the 31.5 Cc. required by the Pharmacopœia test will correspond to 0.0989 Gm. (0.0031396×31.5) of $KMnO_4$, which is equivalent to 98.9 per cent.

According to the Br. P., 1 Gm. of the salt should require 31.2 Cc. of normal oxalic acid for titration, corresponding to 97.89 per cent. of $KMnO_4$. 1 Cc. of the oxalic acid solution represents 0.031374 Gm. of the salt (Br. P. atomic weights).

Acidum Permanganas.—*Permanganic acid.* $HMnO_4$.—This acid may be obtained in pure form by electrolyzing a solution of potassium permanganate between poles separated by a porous cup. Caustic potash accumulates at one pole and permanganic acid at the other. The acid solution is deep purple in color and stable. Pure salts of the various metals can be obtained from it.

Condy's Fluid.—A disinfecting liquid obtained by dissolving 53 parts of potassium permanganate and 333 parts of crystallized aluminum sulphate in 777 parts of hot water. On cooling, potash alum crystallizes out, which is separated from the liquid. The latter hence consists of a solution of sulphate and permanganate of aluminum.

Action and Uses.—When brought in contact with organic matter potassium permanganate is decomposed with the liberation of oxygen, and because of this oxidizing power it is an efficient antiseptic and deodorant. Applied locally in solution it destroys the fetor arising from gangrenous ulcers and wounds, hospital gangrene, cancer, especially of the uterus, abscesses, caries, ozena, sore throat of diphtheria and scarlet fever, etc. The solution used should be from 20 to 60 grains (1.30–4 Gm.) to the pint (480 Cc.): the weaker in the form of lotion, gargle, or applied on a swab to mucous membranes; the stronger as a wash for ulcers, wounds, etc. Solutions varying in strength from 1 : 5000 to 1 : 500 are valuable injections in leucorrhœa and gonorrhœal urethritis. 1 grain (0.05 Cc.) to the ounce (30 Cc.) of water affords a useful deodorizing and palliative irrigation in ozena and fetid otorrhœa. The drug in substance or in saturated solution may be used as a mild caustic. It is popular with some surgeons as a disinfectant for the hands prior to operation. The hands, after thorough scrubbing with soap and water, are dipped into a saturated solution of potassium permanganate, then into a saturated solution of oxalic acid to decolorize them, and finally washed in sterile water. The brown stain made by the salt on the skin or fabric can be removed by oxalic acid. Owing to its oxidizing power it is asserted to be an efficient antidote to snake venom, if placed on the wound before the poison is absorbed or injected hypodermically around the point at which the poison entered. It is also considered a good chemical antidote in poisoning from phosphorus and vegetable alkaloids, particularly morphine, but it renders inert only that part of the poison which has not been absorbed. The quantity used should be about one and a half times the amount of poison ingested. It was first advocated by Ringer in 1882 as an emmenagogue, given in the dose of from 1 to 2 grains (0.05–

0.10 Gm.), 3 times a day, in amenorrhœa, due to exposure to cold or other transient causes, but it is less efficacious than manganese binoxide. Potassium permanganate has been employed internally in dyspepsia, flatulence, obesity, lithæmia, diphtheria, and other diseases, but owing to its rapid decomposition in the stomach it is probably of service only in the first two states mentioned, acting in these by oxidation as a destroyer of the abnormal products present in the stomach. When used in solution it should be dissolved in distilled water, and it should never be mixed in a mortar with any organic substance, as it will explode. It is given in the dose of from 1 to 2 grains (0.05–0.10 Gm.), in tablets or in pills, made with resin, cerate, kaolin, or soft paraffin.

POTASSII SULPHAS, *U. S.*, *Br.*—Potassium Sulphate.

Kalium sulfuricum, P. G.; *Potassæ sulphas, Arcanum duplicatum, Tartarus vitriolatus, Sal polychrestum Glaseri.—Sulphate of potash*, E.; *Sulfate de potasse*, Fr.; *Kaliumsulfat, Schwefelsaures Kali*, G.

Formula, K_2SO_4. Molecular weight, 173.07.

It should contain not less than 99 per cent. of pure salt.—U. S.

Origin.—This salt is present in sea water and in various mineral waters, in the ashes of many plants, in many salt-beds, and in the lava of different volcanoes. It is obtained as a secondary product in many chemical processes, such as the preparation of iodine from kelp, of nitric acid from potassium nitrate, of hydrochloric acid from potassium chloride, and in the purification of potash, etc. It appears to have been prepared in the fourteenth century from the saline residue left in the preparation of nitric acid, and to have been used medicinally by Paracelsus in the sixteenth century. Glaser (1663) prepared it by adding sulphur to melted salpeter.

Preparation.—In the manufacture of the products of the Stassfurt mines potassium sulphate is obtained by decomposing potassium chloride with a hot concentrated solution of *schoenite* (magnesium and potassium sulphates), and separating the newly formed sulphate from the double chloride of potassium and magnesium, which is formed at the same time, before the latter can crystallize. In Kalusz, Galicia, the salt is prepared from *kainite*, a mixture of magnesium and potassium sulphate and chloride, and granulating the newly formed potassium sulphate.

In the laboratory the pure salt may easily be prepared by neutralizing sulphuric acid with caustic potash, evaporating, and crystallizing: $2KOH + H_2SO_4 = K_2SO_4 + 2H_2O$.

Properties.—Potassium sulphate crystallizes in transparent, colorless, and hard 6-sided rhombic prisms or pyramids, or combinations of the two forms. It is permanent in the air, inodorous, has a somewhat sharp and saline, bitterish taste, is neutral to test-paper, has the specific gravity 2.65, and yields a white powder. The salt dissolves at 25° C. (77° F.) in about 9 parts of water and in 4 parts of boiling water (U. S.). It is insoluble in alcohol, but dissolves in about 500 parts of diluted alcohol. The aqueous solution, acidulated with hydrochloric acid, gives with barium chloride a white (sulphate), with platinic chloride a yellow (potassium), and with saturated solution of sodium bitartrate a white (potassium) crystalline precipitate. When heated, it decrepitates strongly, melts at a bright-red heat without decomposition, and at a white heat volatilizes slowly in white non-alkaline vapors, leaving a residue which on cooling is crystalline and has an alkaline reaction; when mixed with an excess of ammonium chloride and ignited it leaves potassium chloride. It imparts a purple color to flame.

Tests.—The aqueous solution (1 in 20) of the salt slightly acidulated with hydrochloric acid, when mixed with an equal volume of hydrogen sulphide solution, should not yield a precipitate or coloration, after standing corked in a warm place for at least half an hour, either before or after addition of ammonia-water to slight alkalinity (absence of metals). 5 Cc. of the solution (1 in 10) should not respond to the modified Gutzeit's test for arsenic given under Arseni Trioxidum.—U. S. The solution should not be precipitated by ammonium carbonate or oxalate (calcium, etc.) nor by silver nitrate (chloride). The solution, mixed with an equal volume of sulphuric acid, should not give a brown or black color on the addition of ferrous sulphate (nitrate). The U. S. P. (1900) omits tests for calcium, chloride and nitrate, the absence of which is demanded by the Br. P. Held in a non-luminous flame it should impart at once a

violet color (absence of sodium). 1 Gm. of potassium sulphate, when completely precipitated by barium chloride, yields 1.338 Gm. of dry barium sulphate.

Action and Uses.—Potassium sulphate, in doses of from ½ to 1 drachm (2–4 Gm.), acts as a gentle aperient, and in larger doses, 2 to 4 drachms (8–16 Gm.), it slowly produces purgation, often with colicky pains in the abdomen. It is not a safe drug to be used in large quantity, as fatal results have followed the administration of from 1½ to 2 ounces (45–60 Gm.). When employed it should be diluted with a large quantity of water. Potassium bisulphate is also a purgative, but it is more powerful and irritating than the sulphate.

Allied Salt.—Potassii Bisulphas. $KHSO_4$. Molecular weight, 135.21.—Potassium bisulphate or acid sulphate is the saline mass remaining in the retort on preparing nitric acid from potassium nitrate and sulphuric acid, and may be obtained in needle-shaped prisms by dissolving it in less than its own weight of boiling water and cooling. The crystals are colorless and transparent, have a strongly acid taste, and acid reaction to litmus, are fusible when heated, congealing on cooling to a translucent mass, and at a higher heat are decomposed with evolution of oxygen and sulphur dioxide, neutral potassium sulphate being left. The salt dissolves without change in 2 parts of cold water, but when dissolved in a large quantity of hot water neutral sulphate crystallizes on cooling, the liquid containing sulphuric acid. A like decomposition into neutral sulphate and acid is occasioned by alcohol.

POTASSII TARTRAS, *Br.*—Potassium Tartrate.

Kalium tartaricum, P. G.; *Potassæ tartras; Tartarus solubilis.—Tartrate of potash, Soluble tartar*, E.; *Tartrate de potasse, Tartre soluble, Sel végétale*, Fr.; *Kaliumtartrat, Neutrales weinsaures Kali*, G.

Formula, $K_2C_4H_4O_6$. Molecular weight, 224.64. The formula given in the Br. P. is $K_2C_4H_4O_6.H_2O$, containing 1 molecule of water of crystallization, but, according to F. B. Power, this is an error, and the formula should be $(K_2C_4H_4O_6)_2.H_2O$. Hager (*Handbuch*, 1902), on the other hand, states that neither the crystals nor the powder contain any water of crystallization, but they absorb moisture from the air and become damp. The Fr. Cod. recognizes the anhydrous salt.

Preparation.—This salt appears to have been known in the sixteenth century. Boerhaave (1742) prepared it by neutralizing cream of tartar with salt of tartar, and named it *tartarus tartarisatus*. That a solution of the same salt is obtained on neutralizing cream of tartar with lime was shown by Rouelle and Marggraf (1770). It is obtained in the first part of the process for making Tartaric Acid (which see), but it is usually prepared by Boerhaave's process, or preferably with potassium bicarbonate, using 25 parts of this salt, 47 parts of pure potassium bitartrate, and about 100 parts of boiling water. The neutral or faintly alkaline solution is concentrated until a pellicle forms and set aside to crystallize; the crystals are drained and dried. The mother-liquor is further concentrated, and when it begins to yield colored crystals may be decomposed by hydrochloric acid to obtain the remaining salt as bitartrate. The yield of crystallized potassium tartrate is about 55 or 56 parts.

If the potassium bitartrate is contaminated with calcium tartrate, this salt may be decomposed by prolonged boiling with potassium carbonate, calcium carbonate being deposited. Calcium tartrate is soluble in a solution of potassium tartrate, and, unless decomposed as stated, is best removed by evaporating the solution to dryness, granulating the salt, and treating it with twice its weight of *cold* water, when most of the calcium tartrate will be left undissolved.

Properties.—Potassium tartrate crystallizes in 4- or 6-sided colorless and transparent crystals of the monoclinic system, which in the presence of calcium tartrate are white and rather opaque. It is more frequently met with as a granular or fine white powder, is inodorous, has a saline, bitterish taste, is without action on litmus-paper, and may be heated to 100° C. (212° F.) without losing in weight; but near 220° C. (428° F.) about 5.5 per cent. of acetone and other volatile products are formed, the residue containing potassium carbonate; above this temperature the salt becomes colored, melts, gives off inflammable vapors having the odor of burning sugar, and leaves a black residue having an alkaline reaction and effervescing strongly with acids. Heated with sulphuric acid, it forms a black, tarry fluid, evolving inflammable gas and the odor of burning sugar. It requires 240 parts of boiling alcohol for solution, and is nearly insoluble in cold alcohol.

1 part of water dissolves 1.3 parts of the salt at 17.5° C. (63.5° F.) and 2.8 parts at 100° C. Tests for tartrate and impurities are the same as given under POTASSII ET SODII TARTRAS. A 5 per cent. solution of the salt acidulated with nitric acid should at most become opalescent on the addition of silver nitrate (chloride).—P. G. The Br. P. requires that 1 Gm. of the salt, converted to carbonate by heating to redness, be neutralized by 8.4 Cc. of normal sulphuric acid when titrated, corresponding to 98.08 per cent. for the formula $(K_2C_4H_4O_6)_2.H_2O$ or 101.83 per cent. for the Br. P. formula. Evidently the formula suggested by Power is better, and, as he states, 8.5 Cc. of normal acid is a better requirement than 8.4 Cc., the former volume corresponding to 99.25 per cent. of the salt, which would be in accord with the demand of the Br. P. that only the slightest reactions with the tests for calcium, magnesium, sodium, chlorides, or sulphates should be afforded by the salt.

Action and Uses.—Potassium tartrate is a mild refrigerant diuretic in small doses and a laxative in large quantity. As a diuretic it differs from the bitartrate in that it renders the urine alkaline. Its purgative action is not as efficient as that of magnesium or sodium sulphate, but it may be used when a mild, aperient effect is desired. Combined with senna, gamboge, or scammony it lessens the griping produced by these drugs. Potassium tartrate is given in the dose of from ½ to 1 drachm (2–4 Gm.) as a diuretic, and from ½ to 1 ounce (16–30 Gm.) as a purgative.

POTASSIUM.—Potassium.

Potassium, Fr.; *Kalium*, G.

Symbol, K. Atomic weight, 38.86.

Potassium is a member of the family of alkali metals, which have been referred to under CÆSIUM and LITHIUM (which see). It occurs widely distributed in nature, as may be seen by referring to the various official salts, but the one great deposit of potassium compounds which are available for commercial purposes is the Stassfurt mine in Germany, where potassium exists as chloride and sulphate, usually in combination with magnesium chloride and sulphate. These minerals are known as carnallite, kainite, silvite, schönite (see under MAGNESIUM), and are of great value in the manufacture of potassium salts and of fertilizers. These salts occur in layers overlying enormous beds of rock-salt, all of which were deposited in remote times from sea water. The source of the potassium salts originally was the feldspars, micas, etc., which suffered decomposition by weathering processes, and yielded the potassium compounds (silicate) to rain waters and rivers, and through the latter to the sea. (See under KAOLIN.)

Preparation.—The metal was first isolated in 1807 by Sir Humphrey Davy, by electrolyzing molten caustic potash, and much is obtained at the present day by electrolyzing molten potassium chloride (see POTASSII HYDROXIDUM). The oldest method of preparing it commercially consists in heating a mixture of potassium carbonate and carbon, for example, charred cream of tartar, to strong redness, when carbonic oxide is produced and the metal distils over: $K_2CO_3 + 2C = 2K + 3CO$. Other methods consist in heating caustic potash or potassium sulphide with aluminum, magnesium, iron, iron carbide or carbon; thus, $2KOH + 2Mg = 2K + 2MgO + 2H$ and $K_2S + Fe = 2K + FeS$.

Properties.—Potassium is of silver-gray color, of a strong metallic luster, harder than sodium, but softer than lead, fuses at 62.5° C. (144.5° F.), is brittle at the freezing-point of water, and at a red heat volatilizes, forming green vapors. Its density is 0.865 and its atomicity univalent. It has a great affinity for oxygen, and when thrown upon water decomposes this liquid, melts, and burns with a purple flame. It must be preserved under petroleum naphtha, which is free from oxygen. There are three oxides of potassium known—the *monoxide*, K_2O, *dioxide*, K_2O_2, and *tetroxide*, K_2O_4, of which only the former is of importance on account of the uses in medicine and the arts to which its combinations with water and acids are put.

Potassium Salts.—Potassium hydroxide is a very strong base, and completely neutralizes the strongest acids. The salts are colorless unless the acid has a distinct color, and are neutral to test-paper, except those with weak acids, which have a distinct alkaline reaction. They are mostly readily soluble in water, and in such solutions, if not too dilute, are precipitated in a gelatinous condition by hydrofluosilicic acid, and in a crystalline form by tartaric acid, acid sodium tartrate, sodium cobaltic nitrite, platinic chloride, and

sodium picrate. The last three precipitates are yellow, the others white. When heated before the blowpipe, the potassium salts impart a purplish tinge to the flame, which is masked by the presence of a small quantity of sodium salt. The yellow color of the latter is absorbed by looking at the flame through blue glass, and the potassium flame becomes then visible.

UNOFFICIAL POTASSIUM COMPOUNDS.

Potassii Bisulphis.—*Potassium bisulphite.* $KHSO_3$.—It is prepared by passing into a concentrated solution of potassium carbonate an excess of sulphur dioxide and adding strong alcohol. The salt crystallizes in white needles, has a sulphurous taste and neutral reaction to test-paper, and on exposure slowly evolves sulphur dioxide. On passing sulphurous acid gas into a warm saturated solution of potassium carbonate the liquid finally becomes greenish, and on cooling deposits hard, glossy, tabular crystals of *potassium pyrosulphite*, $K_2(SO_2)_2O$, which have a saline taste, and on heating give off sulphur and sulphur dioxide, leaving potassium sulphate. Potassium bisulphite or sulphite given in the quantity of from 2 to 4 drachms (8–16 Gm.) in 24 hours exercises a mild, diuretic effect. They possess some power to control fermentation in the intestinal canal, but are now rarely employed for this purpose.

Potassii Bromas.—*Potassium bromate*, E. ; *Bromate de potasse*, Fr. ; *Kaliumbromat Bromsaures Kali*, G. $KBrO_3$.—This salt is formed when bromine is added to hot caustic potash, along with potassium bromide (see the latter). The bromate is separated from the bromide by crystallization, being less soluble than the latter. It forms colorless cubes or tablets, soluble in 15 parts of cold and 2 parts of hot water. Like potassium chlorate it forms dangerous mixtures with combustible substances, such as sulphur, sugar, etc., on account of its oxidizing powers. Silver bromate is difficultly soluble, while silver chlorate is easily soluble. It is used for analytical purposes because it liberates bromine in an acidified solution of potassium bromide: $5KBr + KBrO_3 + 3H_2SO_4 = 3H_2O + 3K_2SO_4 + 3Br_2$. A mixture of the two salts in the proportion given by the equation and diluted to decinormal strength is known as Koppeschaar's Solution, and is employed in titrating phenol, producing tribromphenol.

Potassii Cantharidas.—*Potassium cantharidate.* $C_{10}H_{14}K_2O_6.2H_2O$.—If cantharidin be heated with twice its weight of potassium hydroxide and 100 parts of water in a flask on a water-bath, a clear solution of potassium cantharidate will be obtained; the solution is usually diluted by the gradual addition of warm water to such an extent that each Cc. shall contain 0.0002 Gm. of cantharidin. The salt may be obtained in crystals having the above composition and soluble in 25 parts of water; the addition of acids to the aqueous solution causes the separation of cantharidin, not cantharidic acid, which latter has never been obtained in a free state. Potassium cantharidate was first recommended by Liebreich in 1891 for hypodermic injection in the treatment of certain forms of tuberculosis. The average dose for adults is 1 to 1.5 Cc. of a solution of the salt representing 0.0002 to 0.0003 Gm. ($\frac{1}{324}$–$\frac{1}{216}$ grain) of cantharidin.

Potassii Chloridum, *s. Kalium chloridum* (*chloratum*), *Sal digestivum Sylvii.*—*Potassium chloride*, E. ; *Chlorure de potassium*, *Sel digestif*, Fr. ; *Kaliumchlorid*, G. Formula, KCl.—It is obtained in large quantities at Stassfurt from *carnallite*, a double chloride of potassium and magnesium, and forms white or colorless, inodorous cubes or quadrangular prisms which have a saline taste resembling that of table-salt, and which are fusible without decomposition. The salt dissolves in 3 parts of cold and a little less than 2 parts of hot water, and is slightly soluble in alcohol, but is insoluble in absolute alcohol. Its aqueous solution should have a neutral reaction, and should be free from impurities when tested as directed under the official salts. It should not be confounded with potassium chlorate nor with chlorinated potassa. It is largely employed in the manufacture of other potassium compounds.

Potassii Glycerophosphas.—*Potassium glycerophosphate*, $C_3H_7O_3.PO_3K_2$.—This salt is very hygroscopic, with an alkaline reaction, becoming dry only after long heating to 140° to 150° C. (284°–302° F.). It also occurs in the market as a 50 per cent. aqueous solution. It is used for the same purposes and in small doses as the calcium salt.

Potassii Iodas.—*Potassium iodate*, E. ; *Iodate de potasse*, Fr. ; *Kaliumjodat*, *Jodsaures Kali*, G. KIO_3.—This salt is left behind on treating the product of the reaction of iodine upon potassa with alcohol; or it may be prepared, according to L. Henry (1870), by diffusing 127 parts of iodine in cold water, passing chlorine into it until iodine chloride, ICl, has been formed, and dissolved in water, adding 122.5 parts of potassium chlorate and heating, when chlorine gas will be evolved, and potassium iodate crystallizes on cooling; $ICl + KClO_3$ yields $KIO_3 + Cl_2$. The salt crystallizes in translucent or milk-white cubes, dissolves in 13 parts of cold and in 3.1 parts of boiling water, and is more freely soluble in solution of potassium iodide and insoluble in alcohol. When heated, the salt fuses, and at a high temperature parts with its oxygen, leaving potassium iodide. It detonates, but less violently than the chlorate, when thrown upon burning coal. On the addition of arsenous acid or stannous chloride the solution separates iodine; if not too diluted, its solution yields white granular precipitates with salts of barium, lead, and silver.

Potassii Osmas.—*Potassium osmate.* $K_2OsO_4.2H_2O$.—This salt is preferred by many to pure osmic acid (see page 48). It is prepared by adding potassium hydroxide to an alcoholic solution of osmium tetroxide; the liquid assumes a beautiful red color; and if concentrated, the potassium osmate will separate as a crystalline powder. Slow evaporation of dilute solutions produces deep garnet-red crystals of octahedral shape, which are readily soluble in water, of a sweetish, astringent taste, and permanent in dry air; in moist air the salt deliquesces and is decomposed; hence solutions of the salt are not very stable. Potassium osmate is generally used hypodermically in the form of a 1 per cent. solution; internally it may be given in pill-form, in doses of 0.001 to 0.0015 Gm. ($\frac{1}{65}$—$\frac{1}{45}$ grain).

Potassii Perchloras.—*Potassium perchlorate.* $KClO_4$.—To obtain it, potassium chlorate is carefully heated until it melts and just begins to evolve oxygen, and is kept at this temperature until gas is no longer given off, and a portion of the residue, on being tested with strong hydrochloric acid, acquires only a faint-yellow color. The saline mass is dissolved in water and freed from chloride by recrystallization. Potassium perchlorate is in colorless rhombic crystals which have a slight saline taste, and when heated to about 400° C. (752° F.) is decomposed into oxygen gas and potassium chloride. It is insoluble in alcohol, and dissolves in 5½ parts of boiling water, but requires at 15° C. (49° F.) 65 parts, and at 10° C. (50° F.) 88 parts, of water for solution. This salt is employed in preparing *perchloric acid*, for which Bullock (1865) devised the following process: Potassium perchlorate is distilled with twice its weight of sulphuric acid mixed with $\frac{1}{10}$ part of water. The distillate, containing perchloric, sulphuric, and a little hydrochloric acid and chlorine, is carefully treated with lead carbonate until the sulphuric acid has been completely precipitated. The liquid is filtered, freed from lead by hydrogen sulphide, filtered again, and boiled until it attains a specific gravity of about 1.6, when by distillation it may be obtained of the density 1.693. It is a colorless, oily, very acid liquid, containing 72 per cent. of $HClO_4$, boiling at 203° C., and not affected by sunlight or by sulphurous or hydrochloric acid, but readily decomposed by iodine and bromine. The acid is monobasic, forms mostly deliquescent salts, which are also soluble in alcohol, and when added to not too dilute solutions of potassium salts produces precipitates of potassium perchlorate. This salt is said not to possess the irritating and poisonous properties of potassium chlorate. It has been proposed as an antiperiodic in malaria, but is never used as such.

Potassii Persulphas.—*Potassium persulphate*, E.; *Kaliumpersulfat*, G.; *Anthion.* $K_2S_2O_8$.—A salt of persulphuric acid, obtained by electrolysis of a solution of potassium bisulphate. It forms colorless prisms soluble in 50 parts of water. It oxidizes sodium thiosulphate to sulphate, hence is used in photography.

Potassii Picras.—*Potassium picrate*, E.; *Kaliumpikrat*, *Pikrinsaures Kalium*, G. $C_6H_2(NO_2)_3OK$.—This is obtained by neutralizing a hot solution of 20 parts of picric acid with 7 parts of potassium carbonate and crystallizing in a cool place. It forms small yellow crystals or a powder, soluble in 230 parts of cold and 15 parts of boiling water, and nearly insoluble in alcohol. The salt is bitter and explodes by pressure, a blow, or by heating. It should be kept in a bottle with a cork and not a glass stopper, to avoid friction.

Potassii Sozoiodolas.—*Potassium sozoiodolate.* $C_6H_2I_2(OH)SO_3K + 2H_2O$.—A colorless salt soluble in 84 parts of water and 200 parts of alcohol. Used as a 3 per cent. dusting-powder with talcum or in ointments (3 per cent.) in skin diseases.

Potassii Sulphis.—*Potassium sulphite*, E.; *Sulfite de potasse*, Fr.; *Kaliumsulfit*, *Schwefligsaures Kali*, G. $K_2SO_3.2H_2O$.—On passing sulphur dioxide into a solution of potassium carbonate until the carbon dioxide has been expelled, and adding an equal weight of potassium carbonate, the sulphite, having the above composition, will crystallize on evaporation. It forms octahedral crystals, which are inodorous or of a slight sulphurous odor, somewhat deliquescent, dissolve freely in water, sparingly in alcohol, show an alkaline reaction to test-paper, and have a bitter saline and sulphurous taste. On exposure to the air it is oxidized and gradually converted into sulphate; it should therefore be preserved in well-stoppered bottles. On adding sulphuric or hydrochloric acid to its solution the odor of burning sulphur is given off, but no turbidity from liberated sulphur is produced (difference from thiosulphate). The commercial salt is usually in the form of white opaque crystalline fragments or powder, obtained by evaporating the aqueous solution. For tests and titration, see Sodii Sulphis. For action and uses, see Potassii Bisulphis.

Potassii Telluras.—*Potassium tellurate.* K_2TeO_4.—This compound and the corresponding sodium salt, Na_2TeO_4, are prepared by neutralizing an aqueous solution of pure crystallized telluric acid with potassium and sodium hydroxide, respectively, evaporating the solution to dryness, and washing the residue with alcohol. Both salts occur as a white crystalline powder, readily soluble in water, but insoluble in alcohol; a 2 per cent. aqueous solution should not at once yield a black precipitate upon addition of stannous chloride solution, showing absence of tellurious acid. The alkaline tellurates have been recommended as antihydrotics in daily doses of 0.05 Gm. (about $\frac{4}{5}$ grain), to be given at bedtime; they have been used with effect in arresting the night-sweats of phthisis, but cause an intense garlicky odor of the breath, which is but slightly modified by peppermint.

PRIMULACEÆ.—The Primrose Family.

A family of 28 genera and about 350 species, distributed throughout almost the entire globe, but especially abundant in the north-temperate zone. Their economic importance is almost wholly in the direction of ornamentation, some of our most pleasing household flowers, primroses, cyclamens, etc., pertaining to this family. Medicinally, many species are interesting because of the presence in them of saponin and other bitter principles, or of salicylates.

Primula, Primrose, Cowslip, Lady's-keys, Culverkeys, Herb Peter, Palsywort (E.); *Primel, Schlüsselblume* (G.); *Primavire* (Fr.); *Primavera* (Sp.), is the plant *Primula officinalis* Jacq. (*P. vulgaris* Hill). The part mostly used is the rhizome and roots, under the name *Radix arthritica* or *Radix paralysans*. The plant is an acaulescent perennial of Europe and northern Asia, very commonly cultivated in gardens, and blooming in early spring. The subterranean portion consists of a short, upright, brownish, and scaly root-stock, beset with a number of fleshy roots, and containing a thick mealy bark and a yellowish meditullium. The flowers are pendulous upon short or elongated scapes in umbels of 10 or 12; the calyx is 12 Mm. ($\frac{1}{2}$ In.) or more long, pentangular, tubular, somewhat inflated, acutely lobed, and pale yellowish; the corolla is about 25 Mm. (1 In.) long, funnel-shaped, 5-lobed, the lobes obcordate, of a lemon-yellow color, and has in the throat 5 saffron-colored spots. The corolla alone is sometimes collected for the drug (*flores primulæ*). It has when fresh a honey-like odor and a sweetish taste, and on drying usually acquires a dark-greenish color. The fresh root has a slight sweetish odor and a sweetish, afterward bitterish and acrid taste. The odor of the root and flowers appears to be due to a small quantity of a butyraceous volatile oil. The *primulin* of Hünefeld is considered by Gmelin to be identical with mannit. The acrid principle is either saponin or closely related to it; Saladin (1830) regarded it as identical with cyclamin.

Nearly a dozen other species of *Primula* agree with *P. officinalis* in properties and, for the most part, in uses. *P. obconica* Hance is a well-known irritant poison, the symptoms being those of saponin-poisoning, and is used in the treatment of eczema and other skin diseases.

Two or three species of *Androsace* are similarly used.

Cyclamen, *Sow-*, *Swine-*, or *Ground-bread* or *Bleeding-nun* (E.); *Erdbrod, Schweinbrod, Erdscheibe* (G.); *Pain de porceau, Arthanite* (Fr.); *Pan de puerco* (Sp.) is the tuber of *Cyclamen Europœum* L. The plant is a perennial herb of Europe, well known in cultivation. Its leaves are all radical, roundish, cordate, long-petioled, purple underneath, white-blotched above. The scapes bear solitary, large, nodding, pink flowers, the perianth segments strongly reflexed. The pyriform or spindle-shaped tubers of *Lathyrus tuberosus* L., which are of the size of a walnut, are said to be occasionally substituted for those of cyclamen; they have a mucilaginous taste. The tuber is 25 to 50 Mm. (1–2 In.) thick, flattish circular or depressed globose, dark brown externally, internally white, mealy, with a rather thin bark, and with narrow and short fibro-vascular bundles arranged in irregular circles. In the fresh state it has a burning, acrid taste; after drying, this is milder. The important constituent is the saponin-like body *cyclamin* or *arthanitin*, $C_{20}H_{24}O_{10}$. It is white, amorphous, or in minute crystals, of a bitter and acrid taste, soluble in carbon disulphide, chloroform, alcohol, and water, and insoluble in ether and fixed and volatile oils. Its aqueous solution foams like soap-water, is precipitated by tannin, and when boiled with dilute acids yields glucose and resinous *cyclamiretin*.

Most species of the genus have been more or less employed similarly. Similar properties are said to pertain to various species of *Lysimachia* or *Loosestrife*, especially *L. nummularia* L., the *Creeping loosestrife, Moneywort, Herb tuppence, Wandering-Jennie or -sailor, Pfenningkraut* (G.), *Monnayère* (Fr.), a creeping perennial of Europe, naturalized in the United States, bearing opposite, short-petioled, smooth, rotund, finely punctate leaves, and large, solitary, axillary, bright-yellow, 5-merous flowers.

Anagallis, *Pimpernel, Poor-man's weather-glass, Shepherd's sundial, Red chickweed, Bird's-eye, Waywort* (E.); *Rothe Miere, Gauchheil, Collmarkraut* G.; *Mouron rouge* (Fr.), is the herb *Anagallis arvensis* L., of Europe, and introduced as a weed into many countries. It is a slender, prostrate, spreading annual, with opposite, sessile, oval-ovate, black-dotted leaves, from 5 to 20 Mm. ($\frac{1}{5}$–$\frac{4}{5}$ In.) long, and small scarlet flowers, with crimson centre, on very slender peduncles. The habit of the flowers of opening only in sunshine has given the names "weather-glass," "sun-dial," etc. The herb has an acrid taste, due evidently to the presence of saponin. It has gained some repute in the treatment of rheumatism.

PRUNUM, *U. S., Br.*—Prune.

Pflaume, Zwetsche, G.; *Pruneau noir*, Fr. Cod.; *Ciruela*, Sp.; *Ameixas Passadas*, Port.

The partially dried ripe fruit of *Prunus domestica* L. (Fam. *Rosaceæ*).

The prune is official in most pharmacopœias, some of which, as the British, specify that produced by the *variety Juliana* DC., of the above-named species.

Origin.—The prune tree is a native of southwestern Asia and is now cultivated in all temperate regions. The annual consumption of the fruit as a food is enormous, the

California product now taking precedence of all others as to extent of production. This product is less acid and less highly flavored than the French or European Prune, although larger and finer looking. For this reason it is probably inferior as a laxative, containing a smaller amount of the fruit-salts.

So well known a food-fruit requires no description. The stone with its contained seed should, of course, be removed before using.

Constituents.—The pulp of the prune contains from 35 to 40 per cent. of uncrystallizable sugar in the sweeter varieties, about half as much in the fresh fruit, together with pectin, albumin, and 2 or 3 per cent. of malic and tartaric acids, chiefly the former, partly free and partly combined, mostly with potassium.

The seed contains amygdalin and yields prussic acid, like the bitter almond.

Pharmaceutical Preparation.—Confection of Senna, U. S. P.

Action and Uses.—Prunes are nutritious and laxative, but eaten in excess may produce flatulence and griping. Stewed with sugar and water they form a good article of diet to be taken in habitual constipation. The addition of a small quantity of senna increases their efficiency without affecting their agreeable taste. The presence of prunes in confection of senna and similar preparations lessens the griping of the more powerful ingredients.

PRUNUS VIRGINIANA, *U. S.*—Wild-cherry Bark.

Pruni Virginianæ cortex, Br.—*Rum*, *Whiskey*, or *Cabinet cherry*, E.; *Wildkirschenrinde*, *Amerikanischer Zierstrauch*, G.; *Écorce de cerisier de Virginie*, Fr.; *Corteza de cerezo*, Sp.

The dried bark of *Prunus serotina* Ehrhardt (*Cerasus s.* Lois.; *Prunus Virginiana* Mill.—Fam. *Rosaceæ*), collected in the autumn.

Wild Cherry is official only in the United States and British pharmacopœias. The U. S. P. states that the bark of the very large and of the very small stems is to be rejected. The B. P. does not mention this, and, in fact, specifically refers, in its description, to old and thick bark. The superiority of the young, thin bark has been fully proved.

Fig. 324.

Wild cherry (¾ Nat.).

Fig. 325.

Choke cherry (¾ Nat.).

Origin.—The wild cherry is a small or medium-sized tree, growing in fence-rows, along the borders of forests and in similar exposed or partly exposed situations, through-

out eastern and central North America. Its wood is hard, dark red and handsome, and highly valued in cabinet work. The foliage and inflorescence characters are here illustrated. The small black or black-purple fruit occurs in pendulous racemes. It varies greatly in edible qualities, being sweet, acidulous, and somewhat bitter, but little astringent when ripe. One case of fatal poisoning is recorded from the decomposition of the seeds, with formation of prussic acid, due to impaction of a large quantity of the stones in the intestine. Cattle are frequently killed, apparently by prussic-acid poisoning, after eating the leaves which have been wilted by the sun, although they eat the fresh leaves with impunity. This plant should not be confounded with *P. Virginiana* L. (*Cerasus V.* Lois.; *P. obovata* Bigel.), the Choke cherry, which is commonly only a large shrub, with coarser foliage, and larger, mostly red fruit, which is exceedingly astringent, even when ripe.

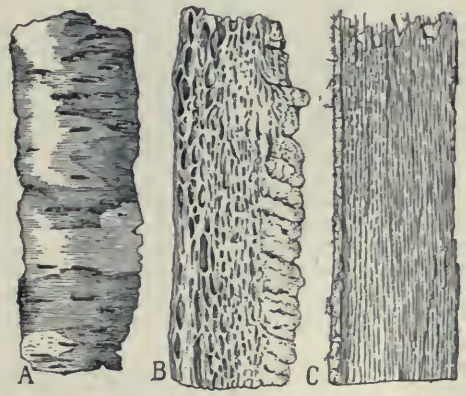
The bark, upon collection, is usually deprived of the periderm, the green phelloderm layer being thus exposed.

Description.—In curved pieces or irregular fragments, 2 to 4 Mm. ($\frac{1}{12}$–$\frac{1}{6}$ In.) thick, the outer surface green or greenish-brown, smooth and somewhat glossy, marked with shallow, transverse, light-colored furrows, the inner surface rusty-brown, either shortly and finely reticulate-striate, or finely and deeply reticulate-pitted by the separation of the tissues in drying; fracture short, granular or rough, the outer layer green, the inner brown, the intermediate purplish; odor characteristic, that from the water-macerated bark strongly resembling that of bitter almonds, as does the taste, which is also somewhat astringent.

The amount of ash should be between 4 and 5 per cent.

The powder exhibits calcium oxalate crystals in various forms, chiefly in rosettes, which are mostly about 17 mikrons broad and which in the bark are contained in cells arranged in regular rows. A few short and thick bast-cells, with somewhat similar stone-cells, occur and starch-grains from 3 to 5 mikrons broad are abundant.

FIG. 326.



Wild-cherry bark: A, outer surface (Nat.); B, inner surface (× 2); C, Choke-cherry bark, inner surface (× 2).

The powder of Choke-cherry bark contains numerous long, slender bast-fibres.

Constituents.—The important constituent of wild-cherry bark is a glucoside very similar to, if not identical with, amygdalin, or perhaps more nearly like laurocerasin, in connection with an enzyme, by the action of which, in presence of water, hydrocyanic acid is freed. For a discussion of this subject, see AMYGDALA AMARA. The yield of hydrocyanic acid is extremely variable, ranging from about 0.03 per cent. in old trunk-bark to about 0.25 per cent. in fresh root-bark. The yield is less in the spring than in the autumn, less in thicker bark, and decreases as the dried bark is kept on hand. There is from 2.5 to 4.5 per cent. of tannin, this also most abundant in the autumn. A small amount of a fluorescent bitter glucoside has been extracted in the form of white crystals.

Pharmaceutical Preparations.—FERRATED WINE OF WILD CHERRY, WINE OF WILD CHERRY, N. F.; FLUIDEXTRACT OF WILD CHERRY, SYRUP OF WILD CHERRY, U. S. P.

Action and Uses.—Owing to the bitter principle contained, wild-cherry bark is a stomachic and bitter tonic useful in gastric atony and general debility. The quantity of hydrocyanic acid which it generates with water is so small that the drug must be given in large quantity to act as a sedative to the bronchial and laryngeal mucous membranes, and even then this effect is so fleeting as to make it of doubtful value. In very large doses wild cherry bark distinctly decreases the rate of the pulse. In quantity much too small to be of benefit it has been employed as a circulatory sedative in the hectic fever of tuberculosis and in cardiac palpitation arising from anæmia, chlorosis, dyspepsia, and nervous disorders.

As a tonic wild cherry is used in the form of the infusion, the dose of which is from ½ to 1 fluidounce (16–30 Cc.), and of the fluidextract in from 30- to 60-minim (2–4 Cc.)

doses. The syrup of wild cherry in the dose of from 1 to 4 drachms (4–16 Cc.) is a pleasant vehicle for other drugs.

Allied Products.—Reference has already been made under Amygdala Amara to the existence in the seeds of the *Drupaceæ* and *Pomaceæ* of Amygdalin or a similar glucoside. The leaves of the cherry, peach, plum, and related plants also contain these substances, with resulting similar properties, and a number of them have been thus employed.

Laurocerasi Folia (*Cherry laurel leaves, Cherry bay leaves,* E.; *Kirschlorbeerblatter,* G.; *Laurier-cerise, Lauroceraso,* Fr.; *Laurel cerezo,* Sp.) are the leaves of *P. Lauro-cerasus* L. (*Cerasus L.* Lois.; *Laurocerasus vulgaris* Car.; *L. officinalis* Roem.). The drug is official in the British Pharmacopœia, which requires the use of the fresh leaves. These leaves are derived from a large evergreen shrub or small tree of southwestern Asia, now largely naturalized in southern Europe. The leaves are about 15 Cm. (6 In.) long, oblong to obovate, narrowed toward each end, the margins sharply serrate and somewhat revolute, the texture thick and coriaceous, the surface smooth and somewhat shining, dark green above, pale underneath, where 1 or 2 rather large depressed glands are found beside the midrib, close to the base. They emit a bitter-almond odor when bruised. The leaves contain 1.3 per cent. of crystallizable, bitter, *laurocerasin* ($C_{40}H_{67}NO_{30}$), which is probably a compound of amygdalin ($C_{20}H_{27}NO_{11}$), amygdalic acid ($C_{20}H_{28}O_{13}$), and $6H_2O$. It is decomposed by "emulsin" into hydrocyanic acid, benzaldehyde (C_6H_5COH), and sugar, but much more slowly than amygdalin, and with only half the yield of HCN. The delay may be due to a preliminary setting free of amygdalin before the fermentation proceeds. The distillate of bruised fresh leaves has yielded 0.12 per cent. of hydrocyanic acid and 0.5 per cent. of benzaldehyde (oil of bitter almonds), some of this latter probably existing already formed in the leaves. The spring leaves are said to give the largest yield. The other constituents are sugar, tannin, fatty or waxy matter, and crystalline *phyllic acid* which is insoluble in water, and soluble in alcohol or ether, and is also found in the leaves of apple, peach, almond, and maple.

Persica or Peach leaves (*Pfirsich,* G.; *Pêcher,* Fr.; *Durazno, Melocoton,* Sp.) is the leaves of *Persica vulgaris* DC. (*Amygdalus Persica* L.). This tree is indigenous to southwestern Asia and is the well-known peach of cultivation. The leaves of cultivation vary extremely in size and are lanceolate, acuminate, finely serrate, glabrous but rugose-wrinkled, and rather thin. They possess the same odor and taste as the other products of this class already considered. They contain about 3 per cent. of amygdalin and yield, like the others, hydrocyanic acid and oil of bitter almond.

PULSATILLA.—Pulsatilla.

Pasque-flower, Easter-flower, Dane's blood, E.; *Küchenschelle, Pulsatille,* G.; *Anemone, Pulsatille, Coquelourd,* Fr.; *Pulsatila,* Sp.; *Anemola,* Port.

The dried herb of *Anemone Pulsatilla* L. (*Pulsatilla vulgaris* Mill.; *P. Pulsatilla* Lyons) or of *A. pratensis* L. (*P. pratensis* Mill.—Fam. *Ranunculaceæ*), collected soon after commencing to flower, carefully preserved, and kept not longer than one year.

The recognition of *Pulsatilla,* Adans., as a genus distinct from *Anemone,* is perhaps judicious, but the terminology of Engler and Prantl is followed in the U. S. P., to preserve uniformity. Pulsatilla is not official in any other of the more important pharmacopœias. The Portuguese prefers *A. nemorosa* L. (*Anemola dos bosques*).

Origin.—Low, delicate, and beautiful perennial herbs, of early spring, the herbage quickly perishing, growing in dry, partially open, and grassy situations throughout most of Europe, and extending into northern Asia; also cultivated for ornament. The second named is rather more abundant southward, the first named northward. Collecting is usually carelessly performed, resulting in the presence of much grass in the drug. Pulsatilla should be dried in the shade. It loses its properties rather rapidly after being dried.

Description.—Silky-villous; leaves radical, long-petioled, the petioles usually purplish, the blades twice or thrice deeply 3-parted or pinnately cleft, the lobes linear and acute; flowers long-peduncled, subtended by a pinnately parted involucre of 3 sessile leaves; calyx of (usually 5 or 6) large, dull-purple, hairy sepals; petals obsolete; stamens numerous; pistils several, becoming in fruit long, plumose-tailed akenes; inodorous and very acrid.

Constituents.—Besides tannin and ordinary plant constituents, Pulsatilla contains a colorless or yellowish acrid volatile oil, the active principle of which is a peculiar crystalline camphor, which is extracted by ether or chloroform and possesses vesicating properties. This is slowly, or rapidly in the presence of water, decomposed into anemonin and iso-anemonic acid. *Anemonin* ($C_{10}H_8O_4$) occurs in colorless, odorless, neutral, friable

crystals, soluble in chloroform, nearly insoluble in ether and water, exceedingly acrid when fused. *Iso-anemonic acid* ($C_{15}H_{14}O_7$) is a white, crystalline, tasteless powder, dissolving in alkalies with a yellow color, insoluble in most common solvents.

Fig. 327.

Anemone Pulsatilla (½ Nat.).

Action and Uses.—It is probable that no drug in the materia medica has been employed in so many different diseases, or has had ascribed to it so divers and conflicting virtues as pulsatilla.

"According to Galen the anemones are endowed with acrid, drawing, cleansing, and opening virtues. When chewed anemone excites a secretion of mucus, its juice cleanses the brain and nostrils and lessens or removes opacities of the cornea. It purifies ulcers, cures lepra and pityriasis, is emmenagogue and galactogogue. Neither Dioscorides, Pliny, nor the Arabians added anything to this enumeration, and the drug seems to have been almost forgotten until the close of the eighteenth century." Since then it has been recommended at different times in the treatment of cataract, paralysis, rheumatism, melancholia, syphilis, dysmenorrhœa, and a host of other morbid conditions.

The bruised fresh fruit and anemonin irritate the skin and may produce vesication. Taken internally it produces a sense of burning in the mouth and fauces and may cause inflammation of the stomach and intestines. In poisonous doses it causes death preceded by cardiac and respiratory depression and convulsions. The dose of the powdered drug is from 2 to 5 grains (0.10–0.30 Gm.); of the extract, ½ to 3 grains (0.025–0.20 Gm.); and of anemonin, ⅛ to ½ grain (0.008–0.025 Gm.).

Allied Drugs.—*Anemone hirsutissima* (Pursh.) (*Clematis h.* Pursh.; *Anemone Nuttalliana* DC.; *A. patens N.*—A. Gray; *Pulsatilla hirsutissima* Britton) is the *American pulsatilla* or *Pasque flower, Easter flower, April fool, Badger-weed, Hartshorn plant, Prairie anemone,* or *P. crocus,* of northwestern North America. It has been found to have the same constituents as Pulsatilla, is used in the same way, and was formerly included in the official definition. It closely resembles Pulsatilla. The genus *Anemone,* L., in the broad sense here considered, comprises about 100 species, many of which have been found to possess similar constituents and properties and a number of which are similarly employed, especially the following: *A. nemorosa* L., the *Wind flower* or *Wood crowfoot, Weisser Waldhahnenfuss* (G.), *A. de bois* or *A. sylvie* (Fr.), common throughout Europe; and its American representative, *A. quinquefolia* L.; *A. coronaria* L., of the Levant; *A. sylvestris* L. and *A. ranunculoides* L., of northern Europe and Asia, and used in Siberia. (See also Ranunculaceæ.)

PULVERES.—Powders.

Poudres, Fr.; *Pulver,* G.

Preparation.—All solid drugs may be reduced to powder, but the means by which pulverization is effected must vary very considerably according to the nature of the drug. The large majority of crystallized chemical compounds are readily powdered by *trituration* in a porcelain or Wedgewood mortar; many of those which are insoluble or sparingly soluble in alcohol may be powdered by *precipitating* them from their concentrated solution by pouring it slowly and with continual agitation into alcohol. Compounds which are insoluble in water may frequently be obtained in a more or less fine powder, which is either amorphous or crystalline, by means of double decomposition and *precipitation.* Soluble compounds may also be powdered by evaporating their solution, and, as it thickens, by stirring it continually, so as to disturb crystallization or prevent the compound from

separating as a solid mass. This process is termed *granulation*, and is equally applicable to fusible substances, which, after having been liquefied by heat, are stirred or triturated while they are cooling and congealing. Volatile compounds and elements (calomel, sulphur, etc.) may be finely powdered by *sublimation*, and by suddenly condensing their hot vapors in a large chamber with a current of air, or, if insoluble in water, with a current of steam.

In several of these processes the powder is not obtained of uniform fineness, and then requires to be *sifted*, or the finer particles are separated from the coarser by means of *elutriation*, which process consists in diffusing the powder in water and decanting from the heavy sediment. The fine powder, which remains longest in suspension, is then permitted to subside, and, after withdrawing the liquid, dried. It is evident that only those substances are adapted to this treatment which are heavier than water, and which are entirely insoluble therein; elutriation is usually preceded by *levigation*, which is simply a process of trituration in the presence of sufficient moisture to render the mass soft. The operation is performed either in a mortar or upon a slab by the aid of a muller.

Drugs which are composed of vegetable tissue or which consist of exudations cannot, as a rule, be reduced to powder by these means. In these cases *contusion* is required, and this is the method most frequently employed. The substance is placed in a rather deep mortar, and broken by perpendicular strokes with the flattened surface of a heavy pestle. The process is called *bruising* if the substance is to be broken merely into a coarse powder. If the drug contains a certain amount of oil or resin, the heat produced by the pounding will often render the material more or less soft or adhesive. This result is best prevented by exposing the drug to a low temperature and powdering in the cold, when it will retain its pulverulent condition at ordinary temperatures, or, if it conglomerates, it may be rubbed into powder by slight trituration. Mortars made of iron or brass are best adapted for preparing powders by contusion. Some tough materials are conveniently reduced to powder by *rasping*.

Most of the vegetable powders are, however, prepared on a large scale at the drug-mills by *grinding*, the grinding surface being a bed of hard stone upon which either iron balls or millstones are made to revolve. A draught is thereby created which carries the fine powder up to a certain height, and if this alone is collected it is called a *dusted powder*. Oily seeds and similar material cannot profitably be powdered in this manner, because by the pressure and heat created by the grinding the oil rises to the surface and agglutinates a part of the powder. Such material is best ground, or rather cut, between horizontal millstones suitably prepared for the purpose. A number of drug-mills which may be worked by hand have been constructed, and serve a good purpose for the use of the pharmacist in preparing the coarser kind of powders, but none have been made which could be used with advantage for finely powdering moderate quantities.

Whether contusion or grinding is resorted to, the drugs to be powdered should be deprived of the moisture remaining in them by exposing them in a drying-room to a temperature of about 50° C. (122° F.). Drugs, however, which owe their virtues to volatile oil, and which should be powdered in the air-dry condition or on a small scale, are conveniently dried over burnt lime. The different tissues of plants are not reduced to powder with equal facility; the fibro-vascular bundles and the bast-fibres are usually more refractory than parenchyma-tissue, and more or less of the former generally remains behind as a coarse powder. When the powder is intended to be exhausted by percolation or otherwise, the coarse particles are utilized with the fine powder; but in case the latter be intended for dispensing, the coarser portion is removed by a sieve. The fine powder which may be sifted off from time to time during the process of powdering should be carefully mixed to ensure uniformity in composition. The fibrous portion of vegetable drugs is usually less active than the remainder, and if in such a case the whole of it be rejected, the resulting powder must necessarily be stronger than the crude drug from which it has been prepared; thus, if the bark of ipecacuanha-root be separated from the wood and powdered by itself, such powdered ipecacuanha will possess an activity about 20 per cent. greater than the root itself.

Fineness of Powders.—The United States Pharmacopœia designates five degrees of fineness—namely, *very fine*, when passed through a sieve of eighty or more meshes to the linear inch; *fine*, when passed through one of sixty meshes; *moderately fine*, through one of fifty meshes; *moderately coarse*, through one of forty meshes; and *coarse*, if passed

through a sieve of twenty meshes to the linear inch. The fineness of powders is often conveniently described as being No. 20, etc., indicating that it has been passed through a sieve of that size.

Compound Powders.—Since nearly all solid drugs may be obtained and kept in the state of powder, the pharmacopœias give special directions only for those powders which are composed of two or more ingredients. In preparing these it is generally advisable to reduce each substance separately to powder; the powders are then weighed out and mixed in a mortar, or are passed repeatedly through a suitable sieve. Some special observations will be made in connection with several official powders.

Mixtures of powdered charcoal or powdered rhubarb with calcined magnesia are likely to cake when made in a mortar with anything like pressure of the pestle; uniformity of mixture is readily obtained by stirring gently together and then passing repeatedly through a bolting-cloth sieve.

Dispensing of Powders.—In the majority of cases when powders are prescribed the ingredients are such as are kept on hand pulverized or in such a condition that they may be easily powdered by trituration in a mortar. The latter ingredients are then weighed out first, and rubbed fine before the powders are added. As in the case of pills, small quantities of toxic remedies are best triturated with some sugar of milk before mixing them with the other powders, so as to ensure more uniform distribution. Should soft substances, such as extracts or liquids, as volatile oils, be directed, they are triturated with the sugar which usually is a constituent of magistral powders until reduced to powder, when the other articles are added and well mixed. In most cases, perhaps, it will be of advantage not to use finely powdered sugar, but to employ sugar in small lumps, which, while being rubbed to powder in the presence of the other ingredients, will tend to cause their still greater subdivision through the prolonged attrition. There are, however, occasional exceptions to the procedure as described, for in consequence of the elevation of temperature produced by the trituration chemical processes are likely to be induced which would interfere with the stability of the powder; such instances are the mixing of oxidizing agents like potassium chlorate with vegetable substances, which under the pressure of the pestle would cause an explosion; or the mixing of salts, which in the presence of a little moisture would result in liquefaction, as in triturating together lead acetate and zinc sulphate. Compound powders of this nature ought invariably to be made by powdering the constituents separately in a mortar; if necessary, they should then be well dried, and finally mixed upon smooth paper with the aid of a spatula, without exerting any friction. Powders intended for external application by "dusting" should be dispensed in an impalpable condition if possible, and for this purpose are best passed through a bolting-cloth sieve of 110 to 130 meshes to the inch.

Powders are rarely prescribed in bulk, except when intended for external use; in nearly all cases they are divided by the pharmacist, each dose being dispensed in a separate paper. Deliquescent and volatile powders should be dispensed in parchment, paraffined, or waxed paper.

Size of capsule.	No.	00.	0.	1.	2.	3.	4.	5.
Bismuth subnitrate	Grs.	20	14	10	8	6	4	2
Cinchonidine sulphate	Grs.	8	6	4	3	2	1½	¾
Dover's powder	Grs.	12	8	6	4	3	2	1
Powdered aloes	Grs.	10	7	5	4	3	2	1
Powdered rhubarb	Grs.	12	8	6	4	3	2	1
Quinine sulphate	Grs.	8	6	4	3	2	1½	¾
Salicin	Grs.	10	7	5	4	3	2	1
Salicylic acid	Grs.	8	6	4	3	2	1½	¾

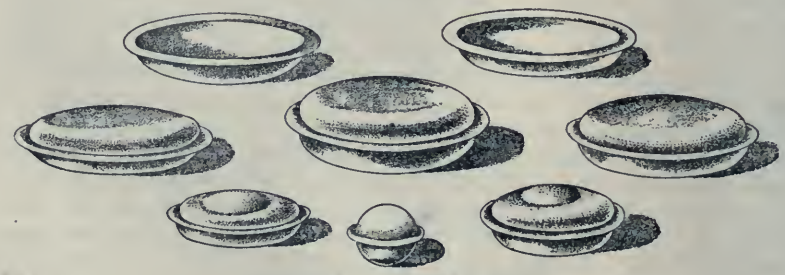
Administration.—Powders are generally taken suspended in water or in a liquid flavored with syrup or some pleasant aromatic. The nauseous taste, however, will not always thus be disguised, and physicians frequently direct the powder to be enclosed in gelatin capsules or in wafers. The filling of definite quantities of a powder into capsules is rather troublesome, on account of the small orifice of the latter, and special

forms of apparatus have been devised to facilitate the operation. The Ihrig Capsule Filler, for sale by Emanuel & Ihrig, Pittsburg, Pa., is one of the best devices ever suggested for filling powders into capsules. Manufacturers of gelatin capsules suggest the table on p. 1263 as a guide for approximate capacity of empty capsules, which will enable pharmacists to make suitable selection without much trouble, bearing in mind, however, that the capacity varies according to the degree of compression exerted in filling.

The use of wafers is not so much in vogue in this country as in Europe, but they are in many respects preferable to capsules; less compression of the material is necessary, and the envelope, made of rice-flour, is more readily distintegrated in the stomach. Sometimes small square or circular sheets of wafer-paper are ordered, and the patient is directed to enclose each dose as wanted; this is done by dipping the wafer into cold water, whereby it is rendered flaccid; it is then laid over a spoon, the powder placed in the centre, and, the edges having been folded over, it is swallowed with a draught of water.

The small round wafers known as cachets are intended to be filled and sealed by pharmacists. Various appliances have been proposed, of which that extensively used in Europe in connection with Mohrstadt's cachets is decidedly the most desirable, as it is simple in construction and quickly operated; the device is sold in this country by J. M. Grosvenor & Co., of Boston, as the "Konseal" filling and closing apparatus. The use of the word "konseal" in place of cachets or wafers does not strike one as particularly appropriate, and is to be regretted. The "konseals," or cachets, are concave disks made of rice-flour and water; they are of convenient form, perfectly digestible, keep permanently for years, and are prepared in six sizes, shown in Fig. 328, varying in capacity from 1 to 10 or 20 grains of dry powder.

Fig. 328.



"Konseals" or rice-flower cachets.

When powders are to be dispensed in wafers it will, of course, be necessary first to make the required number of divisions on paper, either by weighing or measuring with the eye; in Europe a graduated glass tube with hard-rubber piston is said to be used for the same purpose.

Preservation.—When perfectly free from moisture, vegetable powders may be preserved in hermetically sealed vessels; but since they attract moisture on occasional exposure, it is much better to keep them in a dry place enclosed in vessels which will admit the air, but exclude the light. As a rule, such powders will be found to keep well in good paper boxes unless they contain volatile oil.

PULVIS ACETANILIDI COMPOSITUS, *U. S.*—Compound Acetanilide Powder.

Poudre d'acétanilide composée, Fr.; *Zusammengesetztes Antifebrinpulver*, G.

Preparation.—Acetanilide, 70 Gm.; caffeine, 10 Gm.; sodium bicarbonate, 20 Gm. Reduce the ingredients separately to a fine powder and mix them thoroughly.—U. S.

To prepare an ounce of this powder, use 336 grains of acetanilide, 48 grains of caffeine, and 96 grains of sodium bicarbonate.

Compound acetanilide powder is one of the new preparations of the Pharmacopœia. It should be kept in well-stoppered bottles in a dry place. When mixed with water, partial solution takes place, the resulting mixture being alkaline to test-paper.

Uses.—For the uses of this powder, see Acetanilidum. The dose is from 2 to 10 grains (0.10–0.60 Gm.).

PULVIS AMYGDALÆ COMPOSITUS, *Br.*—Compound Powder of Almonds.

Confectio amygdalæ, Conserva amygdalarum.—Confection of Almond, E.; *Conserve d'amandes*, Fr.; *Mandelconserve*, G.

Preparation.—Take of sweet almonds 8 ounces; refined sugar, in powder, 4 ounces; gum-acacia, in powder, 1 ounce. Steep the almonds in warm water until their skins can be easily removed, and when blanched dry them thoroughly with a soft cloth and rub them lightly in a mortar to a smooth consistence. Mix the gum and the sugar, and, adding them to the pulp gradually, rub the whole to a coarse powder. Keep it in a lightly covered jar.—Br.

Uses.—The compound powder of almonds is convenient for preparing almond mixture when mixed with water in the proportion of Gm. 500 in Gm. 75 (2½ ounces to a pint).

PULVIS ANTIMONIALIS, *Br.*—Antimonial Powder.

Pulvis antimonii compositus, Pulvis Jacobi.—James' powder, E.; *Poudre antimoniale de James*, Fr.; *Jamesches Antimonpulver*, G.

Preparation.—Oxide of antimony, 1 ounce; calcium phosphate, 2 ounces. Mix them intimately.—Br.

Antimonial powder is intended as a simplified substitute for a nostrum which has enjoyed considerable reputation in Great Britain and elsewhere for more than a hundred years. Another formula, formerly recognized as yielding a good substitute, requires the ignition of a mixture consisting of 1 part of antimonous sulphide and 2 parts of horn shavings by throwing this in small quantities into a red-hot crucible, powdering the product, and keeping again for some time at a red heat.

A somewhat similar preparation is known here as *Tyson's antimonial powder*, of which two kinds are sometimes employed. One, designated as No. 1, consists of antimonous oxide, 10 parts, and calcium phosphate, 90 parts. No. 2 is made by triturating antimonous oxide, 10 parts, and potassium sulphate, 45 parts, into a fine powder, and adding 45 parts of calcium phosphate.

Uses.—This powder depends for its virtue upon the antimony oxide contained. In doses of from 3 to 10 grains (0.20–0.60 Gm.) it is diaphoretic, and in larger quantity emetic and purgative.

PULVIS AROMATICUS, *U. S.*—Aromatic Powder.

Pulvis cinnamomi compositus, Br.; *Compound powder of cinnamon*, E.; *Poudres des épices, P. des aromates, Poudre aromatique*, Fr.; *Gewürzpulver, Aromatisches Pulver*, G.

Preparation.—Saigon cinnamon, in No. 60 powder, 35 Gm.; ginger, in No. 60 powder, 35 Gm.; cardamom, deprived of the capsules and crushed, 15 Gm.; nutmeg, in No. 20 powder, 15 Gm.; to make 100 Gm. Rub the cardamom and nutmeg with a portion of the cinnamon until reduced to a fine powder, then add the remainder of the cinnamon and the ginger, and rub them together until they are thoroughly mixed.—U. S.

To prepare 4 avoirdupois ounces of aromatic powder use 613 grains each of Saigon cinnamon and ginger and 262 grains each of cardamom and nutmeg.

Grated as finely as possible, the nutmeg is gradually added, with constant trituration, to the crushed cardamom-seed and a portion of the powdered cinnamon, and afterward mixed with the remaining powders. The British Pharmacopœia omits the nutmeg, and directs powdered cinnamon, cardamom, and ginger, of each 1 ounce, to be thoroughly mixed.

Uses.—Aromatic powder given internally may be used alone as a warm stimulating carminative in flatulence, colic or diarrhœa, but it is generally employed as an adjuvant to other drugs to increase their absorption or to correct griping. It may be made into an excellent cataplasm to be applied to the abdomen for the purpose of allaying nausea and colic. When thus employed sufficient of the powder should be enclosed in a flannel or thin muslin bag, and moistened with warm whiskey or vinegar. A better formula than this for a spice poultice or plaster contains equal parts of powdered cinnamon, cloves, allspice, and nutmeg, to which may be added a small quantity of black pepper to produce a more powerful effect. Aromatic powder is given in the dose of from 5 to 15 grains (0.30–1 Gm.).

PULVIS CATECHU COMPOSITUS, *Br.*—Compound Powder of Catechu.

Poudre de cashcuttie composée, Fr.; *Zusammengesetztes Katechupulver*, G.

Preparation.—Take of catechu, in powder, 4 ounces; kino, in powder, rhatany-root, in powder, each 2 ounces; cinnamon-bark, in powder, nutmeg, in powder, each 1 ounce. Mix them.—Br.

Uses.—This powder is a useful astringent in serous diarrhœa. Its administration when the stools contain much mucus should be preceded by a purge. The dose is from 10 to 60 grains (0.60–4 Gm.).

PULVIS CRETÆ AROMATICUS, *Br.*—Aromatic Powder of Chalk.

Confectio aromatica, Lond.—*Poudre de craie aromatique*, Fr.; *Gewürztes Kreidepulver*, G.

Preparation.—Take of cinnamon-bark, in powder, 4 ounces; nutmeg, in powder, 3 ounces; cloves, in powder, 1½ ounces; cardamom-seeds, in powder, 1 ounce; refined sugar, in powder, 25 ounces; prepared chalk, 11 ounces. Mix.—Br.

Uses.—This powder combines the carminative properties of the aromatics with the astringent and antacid effect of the chalk, and may be employed in diarrhœa associated with hyperacidity of the dejecta. There is no good reason for having a fixed formula like this one. The choice of the ingredients and their doses had better be left to the discretion of the prescriber. The dose is from 30 to 60 grains (2–4 Gm.).

PULVIS CRETÆ AROMATICUS CUM OPIO, *Br.*—Aromatic Powder of Chalk and Opium.

Poudre de craie opiacée, Fr.; *Kreidepulver mit Opium*, G.

Preparation.—Take of aromatic powder of chalk, 9¾ ounces; opium, in powder, ¼ ounce. Mix.—Br.

Uses.—The addition of 1 grain of opium to each 40 grains of aromatic chalk powder increases the efficiency of the last-named preparation, particularly when pain is present. The dose is from 10 to 20 grains (0.60–1.30 Gm.).

PULVIS CRETÆ COMPOSITUS, *U. S.*—Compound Chalk Powder.

Poudre de craie composée, Fr.; *Kreidepulver mit Gummi*, G.

Preparation.—Prepared chalk, 30 Gm.; acacia, in fine powder, 20 Gm.; sugar, in fine powder, 50 Gm.; to make 100 Gm. Mix them intimately.—U. S.

Uses.—This powder has been introduced with the view of preparing from it the official chalk mixture as wanted. It should always be made with prepared chalk as directed in the official formula, and not with precipitated calcium carbonate, as has been done at times. Dose, from 20 to 60 grains (1.30–4 Gm.).

PULVIS EFFERVESCENS COMPOSITUS, *U. S.*—Compound Effervescing Powder.

Pulvis sodæ tartaratæ effervescens—Effervescent tartarated soda powder, Br.; *Poudre gazogène laxative*, Fr. Cod.; *Pulvis aërophorus laxans*, P. G.; *Pulveres effervescentes aperientes; Pulvis aërophorus Seydlitzensis.—Aperient effervescing powders, Seidlitz powders* E.; *Poudre gazifère purgative, Poudre de Sedlitz*, Fr.; *Abführendes Brausepulver, Seidlitzpulver*, G.

Preparation.—Sodium bicarbonate, in fine powder, 31 Gm.; potassium and sodium tartrate, in fine powder, 93 Gm.; tartaric acid, in fine powder, 27 Gm. Mix the sodium bicarbonate intimately with the potassium and sodium tartrate, divide the mixture into 12 equal parts, and wrap each part in a separate blue paper. Then divide the tartaric acid into 12 equal parts, and wrap each part in a separate white paper. Keep the powders in well-closed containers, in a dry place.—U. S.

The alkaline powder is usually put into a blue paper, each containing of sodium bicarbonate 2.58 Gm. (U. S., Br.) (2.5 Gm., P. G.; 2.0 Gm., Fr. Cod.), and of potassium and sodium tartrate 7.75 Gm. (U. S., Br.) (7.5 Gm., P. G.; 6 Gm., Fr. Cod). The

tartaric acid is wrapped in white paper, and weighs 2.25 Gm. (U. S.) (2.46 Gm., Br.; 2.0 Gm., Fr. Cod., P. G.). On mixing the solutions of the contents of the two papers, Mr. Wm. Gilmour (1881) observed the formation of potassium bitartrate even in the presence of insufficient tartaric acid for producing neutral sodium tartrate; this effect is due to the liberated carbonic acid.

The mixture of Rochelle salt and sodium bicarbonate is known commercially as Seidlitz mixture: owing to its variable composition, as sold in the market, it is best prepared by the pharmacist himself by mixing 1 part of sodium bicarbonate with 3 parts of Rochelle salt. The small wooden measures intended for dividing the saline mixture and acid are, as a rule, unreliable, and moreover the quantity of powder that can be compressed into these measures varies considerably with the condition of the atmosphere; hence the requisite quantities should be weighed for each paper, being 160 grains of Seidlitz mixture and 35 grains of tartaric acid.

Action and Uses.—This powder presents a pleasant form in which to administer Rochelle salt The reaction between the tartaric acid and the sodium bicarbonate results in the formation of sodium tartrate and carbonic acid. The sodium tartrate enhances the cathartic effect of the preparation, and acts as a mild, refrigerant diuretic, while the carbonic acid gas is a stimulant to the stomach and creates an agreeable sense of coolness in the abdomen. Seidlitz powder is an efficient saline laxative in the early stage of febrile states and to relieve nausea, headache, and constipation or diarrhœa produced by excessive indulgence in food or alcohol. By E. E. Montgomery it is considered the purgative of choice after abdominal operations.

The contents of the white paper should be dissolved in about 2 fluidounces of water, and of the blue paper in about 4 fluidounces of water; the two solutions are then mixed and drunk during effervescence. As much as two sets of powders may be taken if a full purgative effect is desired.

In sick stomach, when the solution of the whole powder cannot be retained, the two powders should be divided into fourths, and a fourth added to a fourth dissolved in a half wineglassful of water, and taken every 15 minutes until an entire powder is ingested. This will often quiet the stomach and produce purgation.

Allied Preparations.—PULVERES EFFERVESCENTES, U. S., 1870; *Pulvis aërophorus anglicus*, P. G.—*Effervescing powders, Soda powders*, E.; *Poudre gazeuse, P. gazogène, P. aërophore, P. de Seltz*, Fr.; *Englisches Brausepulver*, G.—Take of sodium bicarbonate, in fine powder, 360 grains; tartaric acid, in fine powder, 300 grains. Divide each of the powders into 12 equal parts, and keep the parts, severally, of the bicarbonate and of the acid in separate papers of different colors.

PULVIS AEROPHORUS; BRAUSEPULVER (P. G.) is composed of 13 parts of sodium bicarbonate, 12 parts of tartaric acid, and 25 parts of white sugar. Each substance is finely powdered and well dried before the three are mixed, when the powder may be kept unaltered in well-closed vessels. But if these are opened, and from the deposition of moisture decomposition begins to take place, the change proceeds more rapidly in a closed than in an open vessel should the latter be kept in a dry and airy place. The powder keeps much better if granulated as described above. Either form of powder may serve as a vehicle for the convenient and pleasant administration of other medicines, such as salts of iron, quinine, etc., which should not be mixed with the sodium bicarbonate alone.

PULVIS ELATERINI COMPOSITUS, *Br.*—Compound Powder of Elaterin.

Preparation.—Take of elaterin, 5 grains; sugar of milk, 195 grains. Rub them together in a mortar until they are reduced to a fine powder and intimately mixed.—Br.

Uses.—This powder is one-fourth the strength of the Triturati Elaterini (U. S. P.), and is given in the dose of from ½ to 5 grains (0.03–0.30 Gm.). (See ELATERINUM.).

PULVIS GLYCYRRHIZÆ COMPOSITUS, *U. S., Br.*—Compound Powder of Glycyrrhiza (Licorice).

Pulvis liquiritiæ compositus, P. G.; *P. pectoralis Kurellæ.—Poudre pectorale, Poudre de réglisse composée*, Fr.; *Brustpulver*, G.

Preparation.—Senna, in No. 80 powder, 180 Gm.; glycyrrhiza, in No. 80 powder, 236 Gm.; washed sulphur, 80 Gm.; oil of fennel, 4 Gm.; sugar, in fine powder, 500 Gm.; to make 1000 Gm. Rub them together until they are thoroughly mixed.—U. S.

To prepare 1 pound of compound licorice powder use 2 avoirdupois ounces and 385 grains of powdered senna, 3 avoirdupois ounces and 340 grains of powdered glycyrrhiza, 1 avoirdupois ounce and 123 grains of washed sulphur, 30 minims of oil of fennel, and 8 avoirdupois ounces of sugar.

Powdered senna, 2 parts; powdered licorice-root, 2 parts; powdered fennel, 1 part; washed sulphur, 1 part; powdered sugar, 6 parts.—P. G., Br.

The first formula has been adapted from that of the German Pharmacopœia, and is practically identical with it and with that of the British Pharmacopœia. The powder is of a greenish-yellow color.

The present U. S. P. formula, like that of 1890, differs from those of Europe in the use of oil of fennel in place of the fruit, and the increase of powdered licorice-root accordingly; the quantity of oil is based on the assumption that prime fennel will yield 5 per cent. of volatile oil. We regard the change as a very desirable one, since the whole powder can readily be passed through a No. 80 sieve, and will not assume a disagreeable odor by age, which sometimes occurs when it is made with powdered fennel.

Uses.—This is a mild and efficient laxative powder, given in the dose of from ½ to 2 drachms (2–8 Gm.). It is frequently employed for the relief of constipation during pregnancy.

PULVIS IPECACUANHÆ ET OPII, *U. S.*—Powder of Ipecac and Opium.

Pulvis ipecacuanhæ compositus, Br.; *Pulvis d'ipecacuanha opiacée*, Fr. Cod.; *Pulvis ipecacuanhæ opiatus*, P. G—*Compound powder of ipecacuanha, Dover's powder*, E.; *Poudre de Dover*, Fr.; *Doversches Pulver*, G.

Preparation.—Ipecac, in No. 60 powder, 10 Gm.; powdered opium, 10 Gm.; sugar of milk, in No. 30 powder, 80 Gm.; to make 100 Gm. Rub them together into a very fine powder.—U. S.

To prepare 4 avoirdupois ounces of Dover's powder use 175 grains each of powdered ipecac and powdered opium, and 1400 grains of sugar of milk.

Ipecacuanha root, in powder, and opium, in powder, of each ½ ounce; potassium sulphate, in powder, 4 ounces. Mix.—Br.

In the U. S. P. formula the milk-sugar is directed to be used in a rather coarse powder; the fragments of the crystals, being very hard, serve to grind the vegetable powders still finer during the necessarily prolonged trituration. The German Pharmacopœia orders the same ingredients in the same proportions as given above, but directs all three to be separately very finely powdered, and then to be intimately mixed. Both powders are of a pale-brown color and have the odor of opium, somewhat modified by that of ipecac; they differ but slightly in taste, that of the Br. P. being somewhat saline in addition to the bitter and nauseous taste of the other ingredients, which predominates in the powder prepared by the above formula. The Dover's powder of the French Codex is nearly the same as that originally used by Dr. Dover; it is composed of potassium sulphate and nitrate, each 40 parts, and dry opium and ipecacuanha, each 10 parts, the whole to be made into a homogeneous powder.

Action and Uses.—Dover's powder is anodyne and diaphoretic, and is employed with particularly good effect in the forming stages of acute inflammations, such as coryza, laryngitis, pleurisy, bronchitis, pneumonia, etc. Its sedative properties are available in many painful conditions. It may be used to check diarrhœa from transient causes or from such diseases as typhoid fever, tuberculosis, and dysentery. To obtain its full diaphoretic effect it should be administered in one dose of from 10 to 20 grains (0.6–1.30 Gm.), preceded by a hot general bath or mustard pediluvium and followed by hot drinks and the use of warm bed-clothing. As an anodyne the dose of Dover's powder is from 3 to 5 grains (0.20–0.30 Gm.), repeated every 3 or 4 hours.

PULVIS JALAPÆ COMPOSITUS, *U. S., Br.*—Compound Powder of Jalap.

Pulvis purgans, Pulvis jalapæ tartaratus, Pulvis catharticus.—Poudre de jalap composée, Fr.; *Jalapenpulver mit Weinstein*, G.

Preparation.—Take of jalap, in No. 60 powder, 35 Gm.; potassium bitartrate, in fine powder, 65 Gm.; to make 100 Gm. Rub them together until they are thoroughly mixed.—U. S.

Take of jalap, in powder, 5 ounces; acid potassium tartrate, 9 ounces; ginger, in powder, 1 ounce. Mix.—Br.

Uses.—Compound jalap powder is a rather powerful hydragogue cathartic, and is of value in renal or cardiac dropsy in the dose of from 10 to 40 grains (0.60–2.60 Gm.). (See JALAP.)

PULVIS KINO COMPOSITUS, *Br.*—Compound Powder of Kino.

Pulvis kino cum opio.—Poudre de kino opiacée, Fr.; *Kinopulver mit Opium*, G.

Preparation.—Take of kino, in powder, $3\frac{3}{4}$ ounces; opium, in powder, $\frac{1}{4}$ ounce; cinnamon-bark, in powder, 1 ounce. Mix.—Br.

Uses.—This is an astringent and sedative powder which may be used in diarrhœa. Its employment should be preceded by a purge if the alvine discharges contain much mucus. The dose is from 5 to 20 grains (0.30–1.30 Gm.).

PULVIS MORPHINÆ COMPOSITUS, *U. S.*—Compound Powder of Morphine.

Pulvis camphoræ compositus Tully.—Tully's powder, E.; *Poudre de Tully*, Fr.; *Tullysches Pulver, G.*

Preparation.—Morphine sulphate, 1.5 Gm.; camphor, 32 Gm.; glycyrrhiza, in No. 60 powder, 33 Gm.; precipitated calcium carbonate, 33.5 Gm.; alcohol a sufficient quantity. Rub the camphor with a little alcohol, and afterward with the glycyrrhiza and precipitated calcium carbonate, until a uniform powder is produced. Then rub the morphine sulphate with this powder, gradually added, until the whole is thoroughly mixed.—U. S.

This formula originated with Dr. William Tully, of New Haven, Conn. The powder should be very carefully prepared, so that the morphine salt may be uniformly incorporated with the other ingredients. Owing to the volatilization of camphor, it is best to prepare the powder in a small quantity only, and to preserve it in a well-stoppered bottle kept in a cool place. Each grain of the mixed powders contains about $\frac{1}{60}$ grain of morphine sulphate and practically $\frac{1}{8}$ grain of camphor.

Uses.—This powder was introduced by Dr. Tully as a substitute for Dover's powder, but it is certainly less efficient. The dose is from 5 to 10 grains (0.30–0.60 Gm.).

PULVIS OPII COMPOSITUS, *Br.*—Compound Powder of Opium.

Poudre d'opium composée, Fr.; *Zusammengesetztes Opiumpulver*, G.

Preparation.—Take of opium, in powder, $1\frac{1}{2}$ ounces; black pepper, in powder, 2 ounces; ginger, in powder, 5 ounces; caraway-fruit, in powder, 6 ounces; tragacanth, in powder, $\frac{1}{2}$ ounce. Mix.—Br.

This powder contains 10 per cent. of powdered opium.

Uses.—Compound opium powder contains the ingredients, in a dry state, of the confection of opium, and may be used for the same purposes. Dose, 2 to 5 grains (0.12–0.30 Gm.).

PULVIS RHEI COMPOSITUS, *U. S., Br.*—Compound Powder of Rhubarb.

Pulvis magnesiæ cum rheo, P. G.; *P. infantum, s. P. antacidus.—Magnesia and rhubarb, Gregory's powder*, E.; *Poudre de rhubarbe composée*, Fr.; *Kinderpulver*, G.

Preparation.—Take of rhubarb, in No. 60 powder, 25 Gm.; magnesium oxide, 65 Gm.; ginger, in No. 60 powder, 10 Gm.; to make 100 Gm. Rub them together until they are thoroughly mixed.—U. S.

To prepare 4 avoirdupois ounces of compound rhubarb powder use 1 avoirdupois ounce of powdered rhubarb, 2 avoirdupois ounces and 263 grains of calcined magnesia, and 175 grains of powdered ginger.

The official magnesia being the light or bulky variety, it will be found very difficult to mix the powders uniformly if they are put into the mortar promiscuously; the better plan is to mix the rhubarb and ginger, and incorporate the magnesia in small quantities, gradually added, finally passing the whole mixture through a bolting-cloth sieve.

The British Pharmacopœia has adopted Dr. Gregory's formula: Powdered rhubarb, 2 ounces; light magnesia, 6 ounces; powdered ginger, 1 ounce; the mixed powder is to be passed through a fine sieve. Mr. Gilmour (1881) observed that in order to render this powder readily miscible with water the rhubarb and ginger should first be triturated with about 5 per cent. of magnesium carbonate, and the calcined magnesia afterward added.

The formula of the German Pharmacopœia is as follows: Magnesium carbonate, 50 parts; oil-sugar of fennel (1 drop of oil of fennel to 2 Gm. of sugar), 35 parts; powdered rhubarb, 15 parts. Mix.

These powders, when freshly prepared, have a yellowish color, but on keeping gradually assume a reddish tint from the absorption of moisture and the reaction of the magnesia with the constituents of rhubarb; in the presence of water or of alcohol they become deep red.

Action and Uses.—This is a fairly good laxative preparation to be given in cases of acid dyspepsia and diarrhœa with acid stools, particularly in children. The after-constipating effect of the rhubarb detracts from the value of the powder in cases of ordinary constipation. The dose is from 10 to 60 grains (0.60–4 Gm.).

PULVIS SCAMMONII COMPOSITUS, *Br.*—Compound Powder of Scammony.

Preparation.—Scammony resin, in powder, 4 ounces; jalap, in powder, 3 ounces; ginger, in powder, 1 ounce. Mix.—Br.

Action and Uses.—The effect obtained from the combination of drugs so similar in their action as scammony and jalap does not warrant their employment as the only active ingredients of a purgative powder. The modifying action of the ginger is too slight to be of much real value. The dose is from 10 to 20 grains (0.60–1.30 Gm.).

PULVIS TRAGACANTHÆ COMPOSITUS, *Br.*—Compound Powder of Tragacanth.

Preparation.—Take of tragacanth, in powder, gum-arabic, in powder, starch, in powder, each 1 ounce; refined sugar, in powder, 3 ounces. Rub them well together.—Br. It is a white powder, having a sweet mucilaginous taste.

PULVIS GUMMOSUS (P. G.) is used for similar purposes, but has the following composition: Powdered gum-acacia, 50 parts; powdered licorice-root, 30 parts; powdered sugar, 20 parts. It is a yellowish-white powder, having the odor of licorice-root and a sweet, mucilaginous taste.

Action and Uses.—This powder is a useful agent with which to suspend heavy, insoluble powders in liquid mixtures. It may also be used as a demulcent and as a pill excipient.

PYRETHRI FLORES.—Insect Flowers; Insect Powder; Pulvis Insecticidus.

The half-expanded flower-heads of *Chrysanthemum roseum* Web. et Mohr (*Pyrethrum carneum* M. B.) and *C. Marschallii* Aschers. (*Pyrethrum roseum* M. B.), these two yielding the *Blue, Persian,* or *Caucasian insect powder* (*Persische Bertramblüthen, Pyrethrè de Caucase, Chamomile de Perse*), and of *C. cinerariifolium* (Trev.) Bocc. (*Pyrethrum c.* Trev.), this yielding the *White* or *Dalmatian Insect Powder.* (Fam. *Compositæ.*)

Origin.—The insect powders were long exported to us without any information as to their botanical source, but were finally traced to the above-named plants, slender, hardy perennials, very similar to our common daisy, natives of western Asia, where they are cultivated upon a vast scale, great secrecy being maintained as to the methods of cultivation and production. The plants have now been successfully introduced to cultivation in various other countries, and the industry has attained commercial importance in California and northern Africa. Experiments in New York State show that they can withstand the winter and yield an active product, but the trials were purely experimental. Although the plant withstands drouth well, irrigation is found necessary upon the arid plains of California. The yield does not reach commercial importance until the plants

are 3 years old, and they remain at their best for 2 or 3 years. Statements differ as to the relative quality of the flowers before beginning to expand, but it is certain that it deteriorates rapidly after the seed begins to form, and the half-open stage is generally recognized as the most economical for collection. The plants are cut off near the ground and the heads torn off by a sort of combing machine. Statements conflict as to whether they should be dried in the sun or in the shade. By the former method they lose a portion of their volatile oil, but it is claimed that they are then equally active. The probability is that they are then not quite so good. Upon the other hand, the delay attendant upon the slow process of shade-drying exposes them to some danger of deterioration. A similar question exists as to the best method of preserving the powder. While it appears, on general principles, that it should be preserved in tight containers, claims have been made that the powder was equally active after being loosely preserved for a number of years, and even after being entirely deprived of odorous constituents by prolonged heating. Upon the other hand, we have to consider that insects are destroyed by burning the powder in the room which contains them, provided the volatile substances driven off can reach them.

Description.—*Dalmatian Flowers.*—Stem none, or very short; head subglobose, usually a little broader than long, 6 to 12 Mm. (¼–½ In.) in diameter, with irregularly projecting rays; involucral scales light grayish brown or greenish, erect, in 2 or 3 series, lanceolate, obtusish, very finely hairy, the middle portion much thicker and darker; rays in a single series, erect, or the outer more or less recurved, yellowish or brownish white, their length varying with the degree of development; disk yellow, flat, concave or slightly convex, the flowers very small and numerous, the ovaries sharply 5-winged; receptacle nearly flat, or the centre somewhat elevated, naked.

Persian Flowers are similar in form, but usually a little larger, the involucre very dark purple or blackish, its scales narrower and thicker, the rays purple, the ovary 10-ribbed, the receptacle strongly convex.

The Dalmatian powder should have a greenish-yellow color, an odor somewhat resembling tea, and an aromatic and slightly bitter taste. It contains 8 to 10 per cent. of moisture and yields 6.5 to 7 per cent. of ash, almost wholly soluble in hydrochloric acid. The finer the powder, the more efficient its action. The Persian is similar, but somewhat darker, or grayish yellow.

Substitutes and Adulterants.—Absolutely pure insect powder is difficult to obtain. Sophistication begins with the use of the mature or even old heads, and this is to be determined in the powder only by finding the tissues of the seed in various stages of development and by the yield of fat. Next in importance is the use of the stems. The regular practice in the exporting countries was to grind in the stems in the proportion of one-third of the whole. Although we now import the heads entire, great quantities of the stems are still used in this way. The following simple method of assay will serve to detect adulterations readily: Macerate 8 Gm. of insect powder for an hour with 80 Gm. of ether, shaking the mixture frequently. Then decant or draw off 50 Gm., add 1 Cc. of water, and shake thoroughly. Filter, and wash the filter well with ether, transferring filtrate and washings to a tared flask, and distil. Finally, weigh the soft residue. Half-opened buds yield 6 to 7 per cent. of extract, and unexpanded buds from 7.5 to 9.5 per cent. The ethereal extract of pure flowers is of a golden-yellow, dark-yellow, or brownish-yellow color, while that of the stem has a dirty-green tint. Stem adulteration is also detected by microscopical examination, the powder exhibiting numerous large particles of glistening wood-fibre and sclerenchymatic tissue and large hairs sharpened at both ends. Quassia, Quillaja, Fustic, and Chrome-yellow are said to be used, and all increase the ash-percentage, pure insect powder yielding about 7 per cent. of ash. The last named, like Aloes and Curcuma, impart a suspiciously bright-yellow color. Hungarian daisies and other flower-heads have been used, but there is little advantage in the operation from a pecuniary standpoint, because of their expensive nature.

Constituents.—Statements upon this point are very contradictory. It is well established that there is an amount of volatile oil ranging from 0.5 per cent. down to a trace, according to quality, the Persian having apparently the most, and the amount decreasing as the flowers mature; also 4 per cent. (in the Persian) to 7 per cent. (in the Dalmatian) of 2 resins, one soluble in ether, the other, present in more than double the amount of the first, soluble in alcohol. The presence and amount of fatty matter will depend upon the development of the oily seeds. The properties were first supposed to

reside in the volatile oil, but are now known to be retained after this is driven off. It is now generally assumed that they reside in the acid resin, but this idea is apparently negatived by the fact that this can be neutralized without affecting the activity, and that cold water, which does not extract the resin, promptly acquires the toxicity of the powder. The decoction and the alcoholic tincture are equally effective. The presence of a crystalline alkaloid has been asserted, and denied by others. The family relationship of the plant is opposed to the alkaloidal idea. Thoms has reported a glucoside, which is to be expected, but it could scarcely be expected to destroy insects by the burning of the powder. Several analysts have reported a volatile acid. We must conclude, therefore, that the activity of insect powder has not yet been located.

Action and Uses.—Insect-powder, although not poisonous to man, acts as a powerful lethal agent to insects and vermin that infest the bodies of man and animals, and to such as are to be found in bed-clothing, around kitchens, and other parts of the house.

The usual method of application is to sprinkle the powder in such places as are frequented by the insects, and, in the case of man and animals, to apply it to the surface of the body. An infusion or tincture of the powder is not as efficacious as the drug itself. The fumes of the burning powder are also destructive to insects, and when used in this manner small cones or pastilles are made of the powder, added to some gum, and potassium nitrate.

Allied Species.—The genus *Chrysanthemum*, L., contains nearly 150 species, but only a few of them, and these in the section *Pyrethrum*, are known to possess insecticidal properties. Others, possessing the aromatic, bitter properties of the family, will be considered under COMPOSITÆ.

PYRETHRUM, *U. S.*—Pellitory.

Pyrethri radix, Br., P. A.; *Radix pyrethri romani. Pellitory-root, Pellitory of Spain, Spanish chamomile, Longwort*, E.; *Römische Bertramwurzel*, G.; *Pyrèthre officinal*, Fr. Cod.; *P. vrai, Salivaire*, Fr.; *Peritre*, Sp.; *Salivaria*, Port.

The dried root of *Anacyclus Pyrethrum* (L.) DC. (*Anthemis P.* L.; *Matricaria P.* Baill.—Fam. *Compositæ*).

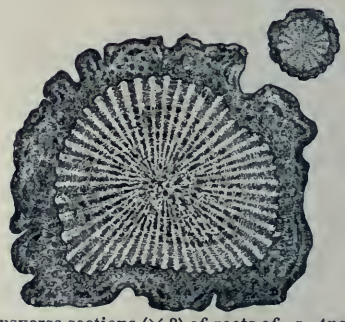
Pyrethrum is official in most pharmacopœias, several of which specify the root of *A. officinarum* Hayne (*German pellitory*, E.; *Zahnwurzel, Speichelwurzel*, G.; *Pyrèthre commun*, Fr.).

Origin.—From a weak perennial herb, resembling the chamomile, but with the ray-florets broadly oval and purplish underneath. It is a native of northwestern Africa and is occasionally cultivated as a garden flower. It is collected in the autumn. Our drug is imported mostly by way of Italy and France, and large quantities are exported to India by way of Egypt.

FIG. 329.

Roman Pyrethrum root (Nat.).

FIG. 330.



Transverse sections (× 3) of roots of—*a*, *Anacyclus Pyrethrum* DC.; *b*, *Anacyclus officinarum* Hayne.

Description.—From 5 to 12 Cm. (2–5 In.) long and 1 to 2 Cm. ($\frac{2}{5}$–$\frac{4}{5}$ In.) thick, nearly straight and unbranched, cylindraceous, tapering or slightly fusiform, bearing a few tough, hair-like, yellowish rootlets, and in the centre of the crown usually a tuft of cottony or silky, whitish, fibrous tissue; externally deep brown, or slightly grayish brown, inconspicuously annular near the crown, very roughly wrinkled and pitted, harsh to the touch; fracture short and sharp; bark thick, the inner layer brown, containing about 3 circles of dark-red resin-cells, the outer layer dark brown; wood yellow brown, finely radiate, containing 4 or more circles of resin-cells; inodorous, pungent, and acrid, producing a prompt and strong sialagogue effect. It should yield from 5 to 6 per cent. of ash.

Constituents.—Pyrethrum contains a brown acrid resin, containing *pelletorin*, which is soluble in alcohol, not in water (*Dunstan* and *Garnett*); 2 potassa-soluble acrid fixed oils, one brown, the other yellow, and the alkaloid *pyrethrine*, which, under the action of alcoholic solution of potassium hydroxide, decomposes into *piperidine* (see PIPER) and pyrethric acid, resembling piperic acid. There is also considerable inulin, a little tannin, volatile oil, and gum. The drug yields about 5 per cent. of washed ether-extract, consisting of resin and fat, which has gone under the name "pyrethreis."

Pharmaceutical Preparation.—TINCTURE OF PYRETHRUM, U. S. P.

Action and Uses.—When chewed, pellitory has an acrid taste, produces a pricking sensation in the mouth and fauces, and increases the secretion of saliva. Applied to the skin, it irritates and distinctly reddens it. Its sialagogue effect has been employed for the relief of headache, neuralgia, and other pains in the head and face. Its stimulating property has been found of value in atonic states of the tongue or pharynx, and in relaxation of the uvula. For these several conditions the root is used as a masticatory in the quantity of from ½ to 1 drachm (2–4 Gm.), or in the form of a decoction or tincture as a gargle.

Little is known of the general physiological action of pellitory, but in a child of 3½ years 50 minims of the tincture produced severe gastro-enteritis, a rapid, weak pulse, and convulsions. The child recovered.

German Pyrethrum or *Pellitory Root*, or *Pyrèthre allemande*, is the root of *A. officinarum* Hayne, cultivated in Germany, its nativity unknown. In foliage and habit it closely resembles the Roman, but the disk of the flower-head is flattish. The root is very long and slender (only about $\frac{1}{8}$ to ¼ In. thick), brown gray externally and dingy white internally. The bark is rather thick and contains 1 circle of rather large resin-cells. The meditullium consists of slender brownish wood-wedges and whitish medullary rays which contain no resin-cells. It is otherwise very similar to the Roman, but comes to market with a considerable portion of the stem adhering. This should be removed before using.

PYRIDINA.—Pyridine.

Pyridinum.—Pyridine, Fr.; *Pyridin*, G.

Formula, C_5H_5N. Molecular weight, 78.48.

Occurrence.—Pyridine occurs in the products resulting from the dry distillation of nitrogenous organic matter, and with its homologues is found in tobacco-smoke, coal-tar, naphtha, etc. Commercially it is produced by refining crude bone oil by treatment with sulphuric acid and subsequent decomposition with sodium hydroxide. The mixture of liberated bases is subjected to fractional distillation, and the distillate, freed from aniline by means of oxidizing agents, is again fractionated. Pyridine has been prepared synthetically by the action of phosphorus pentoxide on amyl nitrate, by reduction of azoamidonaphthalene in alcoholic solution by means of stannous chloride, and also by passing a mixture of hydrocyanic acid and acetylene through a red-hot tube.

Properties.—Pure pyridine is a colorless, limpid, volatile liquid, possessing a peculiar empyreumatic odor and a sharp burning taste. Its specific gravity at 15° C. (59° F.) is 0.98; its boiling-point 117° C. (242.6° F.). It is miscible with water, alcohol, ether, chloroform, and fixed oils in all proportions, but is precipitated from its aqueous solutions by the fixed alkali hydroxides. A glass rod dipped into pyridine, when brought in contact with hydrochloric acid vapor, produces white fumes, as in the case of ammonia. Pyridine has strong basic properties, and combines with acids by addition to form salts, which are crystallizable, hygroscopic, and readily soluble in water. With water the base unites to form a hydrate, $C_5H_5N + 3HO$, which boils at 93°C. (199.4° F.). Pyridine precipitates solutions of ferric, chromic, and aluminum salts as hydroxides, and has the peculiar property of forming crystallizable double salts with salts of the metals, particularly the chlorides of zinc, cadmium, copper, and mercury. Nascent hydrogen converts pyridine into piperidine.

Action and Uses.—Pyridine somewhat resembles coniine in its action; it is, however, less powerful. In toxic doses it profoundly depresses motor centres and nerves, producing marked muscular relaxation, cyanosis, and death from paralysis of the respiratory centre and nerves supplying the respiratory muscles. It is employed in medicine almost solely as a remedy to relax the spasm of bronchial asthma, and is administered by inhalation in the dose of from 5 to 10 drops (0.30–0.60 Cc.).

PYROGALLOL, *U. S.*—Pyrogallol.

Pyrogallolum, P. G.; *Acidum pyrogallicum.—Pyrogallic acid, Trihydroxybenzene*, E.; *Acide pyrogallique*, Fr.; *Pyrogallol, Pyrogallussäure*, G.

Formula, $C_6H_3(OH)_3$. Molecular weight, 125.10.

A triatomic phenol obtained chiefly from gallic acid by careful heating of the same. It should be kept in dark amber-colored vials.—U. S.

Pyrogallol was first obtained by Scheele in 1786 upon heating gallic acid, and was by him considered pure gallic acid. Gmelin pointed out the difference between the two substances, and Pelouze first showed that gallic acid when heated splits up into pyrogallol and carbon dioxide.

Preparation.—When gallic acid is heated with two or three times its weight of water for about ½ hour at a temperature between 200° and 210° C. (392° and 410° F.), under pressure in a suitable boiler, in such a manner that the liberated carbon dioxide can escape, a somewhat colored solution of pyrogallol is obtained; this is boiled with animal charcoal, filtered, and evaporated; when cool a scarcely colored crystalline mass is obtained, which is still further purified by sublimation. Or pyrogallol may be obtained by the direct sublimation of gallic acid (previously dried at 100° C.—212° F.) in an oil-bath at 200° or 210° C. (392° or 410° F.); in this case the yield is rarely more than 25 or 30 per cent., while by the first process nearly the whole theoretical yield (about 75 per cent.) is obtained.

Properties and Tests.—Pyrogallol occurs as light, white, shining laminæ or fine needles, odorless, and having a bitter taste; on exposure to air and light they acquire a gray or darker tint. It is soluble at 25° C. (77° F.) in 1.6 parts of water and in 1 part of alcohol; very soluble in boiling water and in boiling alcohol; also soluble in 1.1 parts of ether. When heated to 132° C. (269.6° F.), pyrogallol melts, and may be sublimed unchanged. Heated rapidly to 250° C. (482° F.), it is converted into the black amorphous *metagallic* acid, which is insoluble in water and has a bitter taste. When ignited, it is consumed, leaving no residue. The aqueous solution, which is at first neutral and colorless, gradually acquires, by exposure to the air, a brown color and an acid reaction due to absorption of oxygen. The same change takes place very rapidly if the solution contains a caustic alkali. The aqueous solution (1 in 10) of pyrogallol reduces solutions of the salts of silver, gold, and mercury even in the cold. When freshly prepared, 1 Cc. of the aqueous solution (1 in 20) is colored brownish red by a few drops of ferric chloride test-solution, and this color is changed to a deep bluish black on the addition of 1 or 2 drops of ammonia-water. A bluish-black color is also produced in the aqueous solution of pyrogallol by freshly prepared ferrous sulphate test-solution.—U. S. The aqueous solution is turned brown by nitrous acid. If lime-water be shaken with pyrogallol, the former assumes a purple color, which soon changes to brown and black, the mixture becoming turbid at the same time.

Pyrogallol heated with phthalic anhydride to 200° C. (392° F.) yields *gallein*, a dyestuff soluble in potassium hydroxide to a blue non-fluorescent solution, and in ammonia with a violet color.

Action and Uses.—The symptoms produced by poisonous doses of pyrogallol are those of a violent, irritant, depressing poison. These symptoms may follow its administration by the mouth or its absorption in large quantity from the surface of the skin. In several cases it has occasioned death, preceded by vomiting and purging, severe abdominal pain, acceleration of the pulse, depression of temperature, cyanosis of the lips, convulsions, and coma. The urine in these cases was dark in hue, and contained albumin and methæmoglobin, the blood was chocolate colored, and the red corpuscles disorganized.

Changes in the liver, almost identical with those caused by phosphorus, have been found in animals poisoned by pyrogallol. Pyrogallol is employed almost exclusively in dermatological practice, and is considered by some a specific in psoriasis. Asserted good results have followed its employment in lupus, leprosy, epithelioma, and parasitic skin diseases. It may be applied in solution or ointment of the strength of 5 to 15 per cent.

The solvents employed are water, alcohol, ether, or collodion, the last possessing the advantage of preventing staining of the linen. The dark-brown stain of the skin caused by the drug will gradually fade, but that of the clothing is indelible.

Concentrated solutions or ointments should not be applied over a large area, for fear of absorption of a poisonous quantity.

Derivative Compounds.—GALLACETOPHENONE.—*Gallactophenone, Trioxyacetophenone, Alizarin-yellow C.* $C_6H_2.(OH)_3C_2H_3O$.—This is a derivative of pyrogallol, in which a hydrogen atom has been displaced by the acetyl group, C_2H_3O. It is formed when a mixture of 1 part of pyrogallol and 1½ parts each of zinc chloride and glacial acetic acid is heated for a short time to 145° to 150° C. (293°–302° F.); upon adding water to the fusion while still hot, gallacetophenone separates, and may be purified by crystallization from boiling water. Thus obtained, it is a crystalline powder of dirty-flesh color and faintly acid or neutral reaction. Gallacetophenone requires 600 parts of cold water for solution, but is readily soluble in hot water, alcohol, or ether, and in all proportions in glycerin; it melts at 170° C. (338° F.). It is readily soluble in alkaline solutions, yielding yellow solutions. The aqueous solution yields a greenish-black precipitate with ferric chloride, and a lemon-yellow lake with aluminium hydroxide.

EUGALLOL.—*Monacetylpyrogallol*, E.; *Pyrogallolmaoacetat*, G. $C_6H_3(OH)_2CH_3CO_2$.—A brownish-yellow transparent syrupy mass, easily soluble in water and acetone. Used as an ointment in 33 per cent. solution in acetone. Applied externally in psoriasis and other skin diseases.

LENIGALLOL.—*Triacetylpyrogallol*, E.; *Pyrogalloltriacetat*, G. $C_6H_3(CH_3CO_2)_3$.—Prepared by boiling 10 parts of pyrogallol, 1 part of sodium acetate, and 25 parts of acetic anhydride for 2 hours, crystallizing the product and washing it with water. A white crystalline powder, insoluble in water, and melting at 165° C. (329° F.). Applied in the form of 0.5 to 5 per cent. ointment in acute eczema, and about 50 per cent. ointment in psoriasis.

SALIGALLOL.—*Pyrogalloldisalicylate.* $C_6H_3(OH)(C_7H_5O_3)_2$.—A resinous solid, insoluble in water, soluble in 2 parts of acetone and 15 parts of chloroform. It is used as a 33 per cent. solution in acetone, similar to lenigallol.

PHLOROGLUCOL.—*Phloroglucin.* $C_6H_3(OH)_3$.—It is an isomer of pyrogallol, and occurs naturally in many plants, and may be obtained by fusing quercetin, maclurin, catechin, or scoparin with potassium hydroxide. It is prepared commercially by fusing 1 part of resorcin with 6 parts of sodium hydroxide until the mass is of a chocolate-brown color, dissolving the mass in water, decomposing it with an excess of sulphuric acid, filtering, and extracting the phloroglucol from the filtrate by means of ether. The residue from the ether solution is purified by sublimation. From water it crystallizes with 2 molecules of water of crystallization, as colorless rhombic plates, having a sweet taste, and which lose their water of crystallization below 100° C. (212° F.). Phloroglucol melts at 210° C. (410° F.) if heated slowly, and at 217° C. (422.6° F.) if heated rapidly (Hartley, Dobbie, Lauder, *J. C. S.*, 1902, p. 930). At higher temperatures it is sublimable. It is readily soluble in water, alcohol, and ether. It is precipitable with basic lead acetate solution, and is colored deep violet with solution of ferric chloride. It is a strong reducing agent, reducing Fehling's solution and ammoniacal silver nitrate solution. With vanillin and hydrochloric acid it yields a bright-red compound. A freshly-cut piece of pine moistened with a 1½ per cent. solution of phloroglucol and then with dilute hydrochloric acid, develops an intense red color. Potassium nitrite added to a solution of phloroglucol and aniline nitrate gradually produces a vermillion-red precipitate.

PYROXYLINUM, *U. S., Br.*—Pyroxylin.

Collodion cotton, Colloxylin, Soluble gun-cotton, E.; *Fulmicoton soluble*, Fr.; *Kollodiumwolle*, G.

A product obtained by the action of nitric and sulphuric acids on cotton, and consisting chiefly of cellulose dinitrate, $C_6H_8(ONO_2)_2O_3$. It should be kept in cartons, protected from the light.—U. S.

Preparation.—The present U. S. Pharmacopœia does not give a process of manufacture. In the 1890 edition the following formula was given, which has been found to yield very satisfactory results: Purified cotton, 100 Gm.; nitric acid, 1400 Cc.; sulphuric acid, 2200 Cc.; alcohol, ether, water, each a sufficient quantity. Mix the acids gradually in a glass or porcelain vessel and, when the temperature of the mixture has fallen to 32° C. (90° F.), add the purified cotton. By means of a glass rod imbue it thoroughly with the acids, and allow it to macerate, until a sample of it, taken out, thoroughly washed with a large quantity of water, and subsequently with alcohol, and pressed, is found to be soluble in a mixture of 1 volume of alcohol and 3 volumes of ether. Then remove the cotton from the acids, transfer it to a larger vessel, and wash it, first, with cold water until the washings cease to have an acid taste, and then with boiling water, until they cease to redden blue litmus-paper. Finally, drain the pyroxylin on filtering-paper, and dry it in small, detached pellets, by means of a water- or steam-bath, at a temperature not exceeding 60° C. (140° F.).

Take of cotton 1 ounce; sulphuric acid, nitric acid, each 5 fluidounces. Mix the acids in a porcelain mortar, immerse the cotton in the mixture, and stir it for 3 minutes with a glass rod until it is thoroughly wetted by the acids. Transfer the cotton to a vessel containing water, stir it well with a glass rod, decant the liquid, pour more water upon the mass, agitate again, and repeat the affusion, agitation, and decantation until the washing ceases to give a precipitate with barium chloride. Drain the product on filtering-paper and dry in a water-bath.—Br.

The French Codex has a similar formula, but somewhat different proportions: It directs the maceration of 55 parts of well-dried cotton in a mixture of 1000 parts sulphuric acid specific gravity 1.84 and 500 parts nitric acid specific gravity 1.42, which has been cooled to 30° C. (86° F.). The German Pharmacopœia directs a mixture of 1000 parts of crude sulphuric acid specific gravity 1.830 and 400 parts of crude nitric acid specific gravity 1.380; when cooled to 20° C. (68° F.), 55 parts of purified cotton are to be macerated in the mixture for 24 hours at a temperature of 15° to 20° C. (59°–68° F.).

Properties and Tests.—Pyroxylin occurs as a yellowish-white, matted mass of filaments, resembling raw cotton in appearance, harsh to the touch; exceedingly inflammable, burning, when unconfined, very rapidly with a luminous flame; less explosive than cellulose trinitrate. Slowly but completely soluble in 25 parts of a mixture of 3 volumes of ether and 1 volume of alcohol. Soluble in acetone and in glacial acetic acid, and precipitated from these solutions on addition of water. It should leave no weighable residue of mineral impurities when ignited. When kept in well-closed bottles and exposed to the light, it is decomposed with the evolution of nitrous vapors, a carbonaceous mass being deposited.—U. S.

A large number of formulas for preparing collodion cotton have been published, many with the nitric acid replaced by a nitrate, and the sulphuric acid correspondingly increased in quantity. Such mixtures may be made to yield as good results as the mixture of the two acids, but, owing to the separation of crystalline sulphates, it is more difficult to imbue the cotton thoroughly and uniformly with the mixture.

In making collodion cotton it is essential that due attention be paid to the strength of the acids, or, if a nitrate is used, to its freedom from chloride; likewise, that the temperature be permitted to fall as indicated before the cotton, which should be free from fat, is introduced, and the cotton be thoroughly imbued with the acid mixture. If introduced at too high a temperature, other insoluble compounds will be produced or the cotton will dissolve and portions not moistened with the liquid will not be acted on, and likewise remain insoluble. Small portions of the cotton may from time to time be examined, thoroughly washed with water, afterward with alcohol, pressed, and then examined as to their solubility in a mixture of ether and alcohol. When these are found to be soluble, the cotton is withdrawn or the whole mixture added to a large bulk of water, the cotton washed with water until free from acid taste, then pressed to free it from water, steeped in alcohol, and again pressed, after which it may be dried by exposure at a moderate temperature. The yield is usually about 140 per cent.

Composition.—Pelouze (1838) obtained explosive compounds by treating cotton, hemp, and paper with strong nitric acid. In 1846 Schoenbein announced the discovery of gun-cotton, and in the same year Otto published a process for preparing it by maceration in fuming nitric acid. In 1848 Maynard employed collodion. That gun-cotton is a nitrated compound of cellulose, and that the weight of the product is greater than that of the cotton employed, was recognized at an early day. At one time the theory was advanced that by the action of nitric acid on cotton one, two, or more hydrogen atoms in the cellulose are displaced by the group NO_2, and thus nitro-compounds formed, to which the name of mono-, di-, tri-, nitro-cellulose, etc., was given. Later investigations have proven that true nitric acid esters are formed, in which one, two, or more hydroxyl groups have been displaced by a corresponding number of groups of the nitric acid radical. The terms cellulose, mono-, di-, tri-, penta-nitrate, etc., are now used to designate the different compounds. All cellulose nitrates give up nitric acid when treated with alkalies, and concentrated sulphuric acid displaces the nitric acid almost completely, even in the cold. The nitrates are also converted back into cellulose by the action of reducing agents, such as ferrous acetate, potassium hydrosulphide, or a solution of stannous chloride in caustic soda. The same change occurs when cellulose nitrate is boiled with ferrous sulphate and hydrochloric acid, the whole of the nitrogen escaping as nitric oxide if air be excluded,

according to the following equation: $2C_6H_7(NO_3)_3O_2 + 18HCl + 18FeSO_4 = 2C_6H_{10}O_5 + 6NO + 6H_2O + 3Fe_2Cl_6 + 6Fe_2(SO_4)_3$. This plan may be used as a ready means of determining the amount of nitration of pyroxylin (Eder). In Germany the name "pyroxylin," which in England and this country is used to designate the soluble nitrates employed in the manufacture of collodion, is restricted to the insoluble and explosive variety better known as gun-cotton, and which is probably a penta- or hexa-nitrate; the name "colloxylin" is there given to the soluble varieties. When the mixture of nitric and sulphuric acids as directed in the official formula is allowed to act on cotton, one or more cellulose nitrates may be formed, dependent upon the temperature employed, the strength of the acids, and the length of time of immersion; the presence of sulphuric acid simply facilitates the elimination of water, which invariably accompanies the formation of ethers. The cotton is apparently not altered in structure and appearance, the staple remaining intact. Official collodion cotton is probably a mixture of cellulose dinitrate and trinitrate ($C_6H_8(NO_3)_2O_3$) and ($C_6H_7(NO_3)_3O_2$), both of which are soluble in a mixture of alcohol and ether.

Similar nitrated compounds are also obtained from other carbohydrates; thus starch yields with concentrated nitric acid a transparent jelly of xyloidin, $C_6H_9(NO_2)O_5$, and a similar change is produced in paper by dipping it into strong nitric acid and afterward washing with water.

Preservation.—When collodion cotton, particularly in the moist state, is kept in well-stoppered bottles, it undergoes decomposition, frequently accompanied with the evolution of nitrous vapors or with ignition and explosion. It is best preserved in a dry atmosphere and enclosed in vessels which permit the free access of air, but should never be compressed tightly.

Pharmaceutical Preparations.—COLLODION.—U. S. P.

Uses.—Pyroxylin is employed in pharmacy in the preparation of collodion and in the arts in the manufacture of transparent varnishes.

Q.

QUASSIA, *U. S.*—Quassia.

Quassiæ lignum, Br.; *Lignum quassiæ*, P. G.; *Jamaica quassia, Quassia-wood, Bitter-wood, Bitter ash*, E.; *Quassiaholz, Fliegenholz*, G.; *Quassie amer, Bois amer*, Fr. Cod.; *Quassie de la Jamaique*, Fr.; *Quassia della Giammaica*, It.; *Quassia amarga*, Sp., Port.; *Pau Quassia*, Port.

The wood of *Picrasma excelsa* (Swz.) Planch. (*Quassia e.* Swz.; *Q. polygama* Lindsay; *Picræna e.* Lindl.; *Simaruba e.* DC.) or of *Quassia amara* L. (Fam. *Simarubaceæ*).

Quassia is official in all pharmacopœias, though most of them do not specify the first-named variety. Those which do, for the most part, employ the synonym "*Picræna.*" Many specify instead the second-named, or Surinam variety. The Portuguese permits the use of both, while others expressly forbid the use of the Jamaica variety.

Origin.—Jamaica Quassia is derived from a small or medium-sized tree of the West Indies, said to resemble an ash tree, whence the name "Bitter Ash." It was originally introduced as a substitute for the older drug, Surinam Quassia, and was later adopted in place of it. The Surinam species is scarcely more than a very large shrub.

Description.—Jamaica Quassia. Occurring in various forms, usually in chips, raspings, or billets, yellowish white or pale yellow, and of rather coarse texture; odor slight; taste intensely bitter; medullary rays containing tetragonal prisms or small, arrow-shaped crystals of calcium oxalate. Billets of Jamaica quassia are usually 12.5 Cm. or more in diameter; in tangential section the medullary rays are mostly 3 to 5 rows of cells in width.

Surinam Quassia. Occurring usually in billets not exceeding 7.5 Cm. in diameter; the wood is heavier, harder, and more deeply colored than that of Jamaica quassia, and the medullary rays in tangential section are mostly 1 or 2 rows of cells in width.

The powder shows irregular calcium oxalate crystals, 8 to 15 mikrons long. In view of the definition, the bark should not be present in the powder, whereas it usually is so in the Surinam variety, large stone-cells being then visible. The ash is frequently stated to be 7 or 8 per cent., but is in reality only half this amount. The Swiss Pharmacopœia mentions that ferric chloride should deepen the color of the aqueous infusion, but cause no precipitate, thus alluding to the absence of tannin.

Constituents.—Although Jamaica Quassia is said to contain traces of a yellowish alkaloid, giving a fine blue fluorescence with acidulated alcohol, the important bitter principle is a neutral, crystalline substance, commonly known as *Quassiin*, but determined by Massute to be a mixture of two crystalline bodies, which he denominated *α-* and *β-picrasmin*. "Quassiin" is extracted by neutralizing the aqueous infusion with soda, precipitating with tannin and decomposing the precipitate with lead oxide or lime. It is commonly said to exist to the extent of only 0.05 to 0.15 per cent., but really exists in much larger amount, Wiggers says 0.75 per cent. This discrepancy is probably due to the fact that it is difficult to procure in a pure state, and that the purification processes involve considerable loss. Quassiin crystallizes in needles or prisms, and is soluble in alcohol and chloroform and in 1200 parts of cold water. Its bitterness is most intense. The *α*-picrasmin ($C_{35}H_{46}O_{10}$) melts at 204° C. (399.2° F.), the *β*-picrasmin ($C_{36}H_{48}O_{10}$) at 209° to 212° C. (408.2°–413.6° F.). The bitter principle of Surinam Quassia is closely related and of similar action, but is not identical.

Pharmaceutical Preparations.—Extract of Quassia, Fluidextract of Quassia, Tincture of Quassia, U. S. P.

Action and Uses.—Quassia is a bitter tonic, employed with much benefit in dyspepsia due to an atonic condition of the gastric mucous membrane. As a stimulant to the appetite in anorexia following the acute fevers it ranks with gentian and cinchona. Large doses are apt to produce vomiting, and its prolonged use, even in moderate medicinal quantity, may result in gastric derangement. An infusion made by adding ½ to 1 ounce (16–30 Gm.) of quassia to 1 pint (480 Cc.) of hot water is an efficient

remedy to be used as an enema for the removal of thread- or seat-worms (Oxyuris vermicularis). The rectum should be thoroughly emptied by an injection of soap and water prior to the employment of the quassia infusion. Quassia may be given in powder in the dose of from 5 to 30 grains (0.30–2 Gm.), but either the tincture in from ½ to 1 drachm (2–4 Cc.) doses, or 10 to 30 minims (0.60–2 Cc.) of the fluidextract, or 1 to 3 grains (0.06–0.20 Gm.) of the extract are preferred. An infusion is often employed by the laity. Since quassia is devoid of tannin it may be added to tonic preparations containing iron salts without producing a bluish-black precipitate. Quassin, in ¼- to ½-grain (0.015–0.03 Gm.) doses, may be substituted for the crude drug.

Allied Drugs.—The barks of both Quassias are somewhat used separately. That of Jamaica Quassia is dark gray to blackish gray, furrowed and warty, yellowish white on the inner surface, and 4 to 8 Mm. (⅙–½ In.) thick. The fracture of the outer layer is smooth, that of the inner tough and fibrous. It is bitter like the wood. Its constituents have not been investigated. That of Surinam Quassia is lighter in color, nearly smooth without, more nearly white on the inner surface, very brittle, and only about ⅕ or ¼ as thick.

The wood of *P. quassioides* (Buch.-Ham.) Benn. (*Nima q.* Buch.-Ham.) is used in an exactly similar way in India. It is a much larger tree than either of the American Quassias, its bark dark brown, reticulate-fissured, and transversely scarred. The wood is light yellow, the medullary rays exhibiting from 1 to 5 rows of cells on tangential section. It will thus be seen that this variety bears a remarkably close similarity to the official. Dymock and Warden found in it a trace of alkaloid, a bitter, resin-like, fluorescing principle, and another bitter crystalline resinous body, as well as a crystalline substance apparently identical with Quassiin.

P. ailantoides (Bunge) Planch. is a Japanese species, there known as "*nigaki*," meaning *Bitter-wood*. The bark is in this case the more bitter part and is described as being very thin, gray, and somewhat shining, the wood yellow. The bark was found to contain a principle very similar to Quassiin.

An African Quassia has been reported as coming from the Congo region, which it is said can scarcely be distinguished from Surinam Quassia, and which yields a principle apparently identical with Quassiin.

Under the name *Iron-wood* or *Ostrya* (also called *Lever-wood* and *Hop hornbeam*), the heart-wood and the bark of *Ostrya Virginiana* (Mill.) W. (*Carpinus V.* Mill.; *O. Virginica* W.), elsewhere considered, are used as Quassia-substitutes.

Samadera.—In the Philippines and in the East Indies the wood of *Samadera Indica* Gærtn. (called "Manungal" in the Tagala dialect) is used as a Quassia-substitute. The seeds are also bitter and yield a fixed oil.

QUERCUS, *U. S.*—White Oak.

Cortex quercus, P. G.—*Stone oak*, E.; *Eichenrinde*, G.; *Écorce de chêne*, Fr.; *Corteccia di Quercia*, It.; *Corteza de Encina*, Sp.; *Casca de Carvalho*, Port.

The dried bark of *Quercus alba* L. (Fam. *Cupuliferæ*), collected from trunks or branches 10 to 25 years of age, and deprived of the periderm.

Quercus, or Oak Bark, is official in nearly all pharmacopœias. Owing to the uniformity with which the barks of different oaks possesses strongly astringent properties, different species are named in different countries, chiefly according to convenience of supply. Thus many pharmacopœias name *Q. Robur* L., *Q. pedunculata* Ehrh., and *Q. sessiliflora* Martyn, the last two quoted by some as De Candolle's varieties of *Q. Robur*, which is the *British* or *English oak*, or *European white oak* (*Steineiche, Sommereiche*, G.; *Chêne blanc*, Fr.). The Russian Pharmacopœia requires that oak bark contain about 15 per cent. of tannin.

Of the many species of oak found abundantly in America, the bark of *Q. alba* is preferred because of its pure astringency, uncomplicated by any specially troublesome coloring- or other matters. The tree, which is sometimes very large, is abundant throughout eastern and central North America, and is represented further west by closely related and similar species. It yields the highly prized American oak timber.

It is generally believed that neither very old nor very young bark is equal to that from medium-sized trunks and large branches; though in Europe that from smaller branches or stems is preferred, so that the bark usually occurs in quills. The bark is collected in early spring, after first scraping off the rough, silvery- or ashy-gray corky layer.

Description.—In nearly flat pieces, 3 to 10 Mm. ($\frac{1}{8}$–$\frac{2}{5}$ In.) thick, of a rough and splintery appearance and loose texture, harsh to the touch, pale brown throughout, or becoming of a pinkish brown upon exposure, the inner surface very coarsely short-striate; fracture tough, coarsely splintery; odor faint, tan-like; taste strongly astringent; not tinging the saliva yellow when chewed.

It usually occurs as an irregularly coarse, splintery-fibrous powder.

FIG. 331.

Quercus alba ($\frac{1}{4}$ Nat.).

FIG. 332.

Quercus alba (Nat.).

Constituents.—The important constituents of White Oak bark are about 7 per cent. of *quercitannic acid* and a variable amount of *oak-red*. This quercitannic acid is yellowish brown, amorphous, yields a brown precipitate with lead acetate, and was found by Stenhouse (1862) to yield sugar when boiled with dilute sulphuric acid. But, according to J. Löwe (1881), this tannin is not a glucoside; it is separated anhydrous ($C_{28}H_{24}O_{12}$) by saturating its solution with sodium chloride; it is almost insoluble in ether, but dissolves readily in acetic ether; it gives yellowish-white precipitates with gelatin, albumen, tartar emetic, and the alkaloids, and when heated with dilute acids under pressure yields *oak-red* ($C_{28}H_{22}O_{11}$). Quercitannic differs from gallotannic acid in not being convertible into either gallic or pyrogallic acid. The infusion of oak-bark yields to ether a little gallic and ellagic acids. The great value of oak-bark for tanning purposes is due to the presence in it of various substances which have the property of "filling" the leather, but which are unimportant from a medicinal point of view. Pectin, resin, wax, fat, lævulin, and the sugar quercit have been found. There is also a very slight amount of an unstudied bitter principle.

Pharmaceutical Preparation.—FLUIDEXTRACT OF QUERCUS, U. S. P.

Action and Uses.—Quercus owes its virtue to the contained tannic acid. Although rarely given internally, its astringent property may be of service in diarrhœa or hæmoptysis. Infusions of the strength of $\frac{1}{2}$ to 1 ounce (16–30 Gm.) to the pint (480 Cc.) of water are used as vaginal irrigations in leucorrhœa due to chronic endometritis, simple or gonorrhœal vaginitis, as astringent rectal injections in hemorrhoids and prolapsus ani, and as a gargle in subacute and chronic inflammations of the tonsils and pharynx. The dose of the fluidextract is from 10 to 60 minims (0.60–4 Cc.).

Allied Products.—Under this head a large number of products must be referred to. They are divisible into two series, one allied merely by composition, and properties or uses, the other through botanical relationship as well. The latter will be first considered.

Quercus, Sps.—The genus *Quercus*, L., comprises more than 200 species, distributed widely through the northern hemisphere. Its products are noted for their astringency. They constitute two series, that represented chiefly by GALLA and ACIDUM TANNICUM being characterized by the presence of gallo-tannic and gallic acids, that represented by the barks by the presence of quercitannic acid. The oak-barks differ among themselves chiefly in the amount of tannin and in the amount and kind of coloring-matter. The tannic acids of the different species appear to be identical as to their own properties, but since they yield different phlobaphenes or coloring-matters, it appears that this cannot be the case. The largest yield of tannin recorded is said to be about 22 per cent., from the bark of *Q. incana* Roxb., of India.

European white oak bark, referred to above, occurs in quills, the bark being about 2 Mm. ($\frac{1}{12}$ In.) thick; the outer surface is gray or brown gray, glossy, and smooth or somewhat fissured; the inner surface is cinnamon colored and somewhat rigid. The bark breaks with a smooth, and in the inner layer with a fibrous, fracture, and in odor and taste resembles the preceding.

Yellow oak bark, also called *Dyers'* or *Quercitron oak*, and incorrectly though commonly in pharmacy known as "Black oak," is the bark of *Q. velutina* Lam. (*Q. tinctoria* Bartr.; *Q. coccinia tinctoria* A. Gray), common in eastern North America. This bark was formerly official, and is largely employed in the arts under the name of *quercitron-bark*. It resembles that of the white oak, but the suberous layer, which is generally removed, is of a blackish-brown color, and the inner bark of a deep reddish brown with a yellowish tint. Like the preceding, it is usually kept as a coarse powder; when masticated it tinges the saliva bright brownish yellow, due to the presence of *quercitrin*, which has been met with in many plants. This is deposited from the decoction of black oak bark on cooling, forms when pure a yellow crystalline, inodorous, and nearly tasteless powder, which is sparingly soluble in hot and nearly insoluble in cold water, dissolves in about 5 parts of alcohol, slightly in ether, is colored dark green by ferric chloride, and dissolved in alkalies becomes dark brown on exposure. Its formula is $C_{33}H_{30}O_{17}$ ($C_{36}H_{38}O_{20}$, Liebermann, 1879). Treated with acids, it splits into the crystalline unfermentable sugar *isodulcit*, $C_6H_{14}O_6$, and into *quercetin*, $C_{27}H_{18}O_{12}$ ($C_{24}H_{16}O_{11}$, Liebermann); the latter is likewise yellow and crystalline, is found ready formed in a number of plants, is colored dark green by ferric chloride, precipitated brick red by lead acetate, sublimable by alkalies, resolved into phloroglucin and *quercetic acid*, $C_{15}H_{10}O_7$, and with fusing potassa yields protocatechuic acid.

This is said to be the species which yields the peculiar galls often called *Oak-plums*.

A great many oak-barks have been examined as to their tannin and coloring-matters, especially by Trimble, but the results are of interest rather to tanners and dyers than in medicine. The astringent properties are not confined to the bark. Under the name *Vallonea* (*Valonia, Acorn-cups*, E.; *Walonen, Knoppern*, G.; *Valloné, Velanédé, Gallon*, Fr.) the scaly involucres of the fruits of various species are employed in tanning. *Oriental valonia* consist of the cups of *Q. vallonea* Klotschy and of several allied species or varieties of *Q. Ægilops* L., indigenous to southeastern Europe and the Levant. They are about 2.5 Cm. (1 In.) or more broad, have thick spreading or recurved scales, and possess a strongly astringent taste. *Hungarian valonia* constitute a combination of cup and gall, being the cups of *Q. robur* L., rendered irregular in shape, and more or less winged, by the excrescences produced by the sting of *Cynips quercis calycis*. The cups of our indigenous species are likewise astringent.

Acorns themselves are astringent, often very strongly so, notwithstanding that the kernels of *Q. alba* and some others are edible, and are used as a coffee-substitute under the name of *Acorn-coffee*. Among other things they contain much starch, protein, fat, and sugar.

Fagaceæ (*Cupuliferæ*).—This family, of which the oaks are the most important representatives, is noted for its abundance of tannin. CASTANEA and GALLA are separately discussed. The bark and leaves of the several species of Beech (*Fagus*) are quite rich in tannin. The nuts of the American beech are edible and excellent. They are said by La Wall to contain upward of 25 per cent. of albuminoids, 30 of fat (double this amount in some selected specimens), and 3.5 of starch, but no sugar.

Other Tannin-yielding Families worthy of note are the following: *Myricaceæ* and *Salicaceæ*—the barks of *Salix* and *Myrica* having been elsewhere discussed. That of *M. Nagi* Thunb. (*M. rubra* Sict. et Zucc.), of India, is there used for tanning and contains 11 to 14 per cent. of tannin. The barks of *Alnus* and other *Betulaceæ* have been referred to under BETULA. In tropical America the barks of many *Melastomaceæ* (especially species of *Tibouchina*, in the Andes) and of many *Malpighiaceæ* are used for tanning. That of *Malpighia glabra* L. is largely used in Mexico under the name of *Nance bark*. It contains 26 per cent. of tannin.

The *Leguminosæ* are especially rich in tannin. Although this statement applies to all divisions of the family, it is especially true of the *Mimosaceæ* and to a less extent of the *Cæsalpiniaceæ*. The bark of the root, and to a lesser extent other parts, of the large shrub or small tree *Cercis Canadensis* L. (*Siliquastrum C.*—Medic.; *S. cordatum* Moench), the

American Judas tree, Salad tree or *Red bud* (*Bouton rouge, Gainier*, Fr.), as well as of the related species *C. Siliquastrum* L. (*Siliquastrum Arbor-Judas* Medic.), the *European Judas tree*, is rich in tannin and is considerably astringent. The barks of many species of *Acacia* are valuable for tanning purposes. In India, *A. Arabica* Willd. yields the much-used *Babul bark*. The pods of this species contain 22 per cent. of tannin and are commercial under the names *Neb-neb* and *Bablah*, and their extract under that of *Akakia*. *Wattle bark* is an Australian product, the *Golden wattle* yielded by *A. pycnantha* Benth., the *Black wattle* by *A. decurrens* Willd. *Algarobilla* is the fruit of *Cæsalpinia brevifolia* Benth. The wood and bark of many species of *Mimosa*, as well as of the closely related genus *Calliandra*, are used in various countries as astringents. That of *C. Houstoni* Benth. is known in Mexico as *Pambotano*. Maiden has listed 10 species of the related genus *Albizzia*, which are used in Australia. In tropical America the barks of various species of *Pithecolobium* are so used. *Cortex adstringens brasiliensis*, which was used in Europe during the first half of the present century, is obtained from *Stryphnodendron polyphyllum* Mart., a tree known in Brazil as *barbatimao* or *barbimao*. The bark is covered with a thick fissured blackish red-brown cork, has a light-brown bast-layer readily separating in bands, possesses a strongly astringent and somewhat mucilaginous taste, and contains about 30 per cent. of tannin, which yields with ferric salts a blackish gray-green precipitate. *Divi-divi*, an Indian product, is the pods of *Cæsalpinia coriaria* Willd. (*Libidibia c.* Schlecht). They contain more than 50 per cent. of tannin. A closely related product is *Tari* or *Teri*, the pods of *C. digyna* Rottl. One-third of their weight consists of tannin suitable for tanning purposes.

The *Dilleniaceæ* is another family rich in tannin. In the Philippines, the wood of *Tetracera macrophylla* Vall. is largely used for hæmoptysis and locally for sore throat, under the Tagala name *Malakatimon*.

The bark of *Odina Wodier* Roxb. (Fam. *Anacardiaceæ*) is abundant and widely distributed in India, and there used for tanning, also as a medicinal astringent. It is used also for rough cordage, and to yield a golden or pale-brown tint in silk-dyeing.

Those interested in this subject will find it useful to refer to *Agricult. Ledger*, 1902, No. 1, which is a pamphlet of 56 pages, devoted to *Indian tanning materials*.

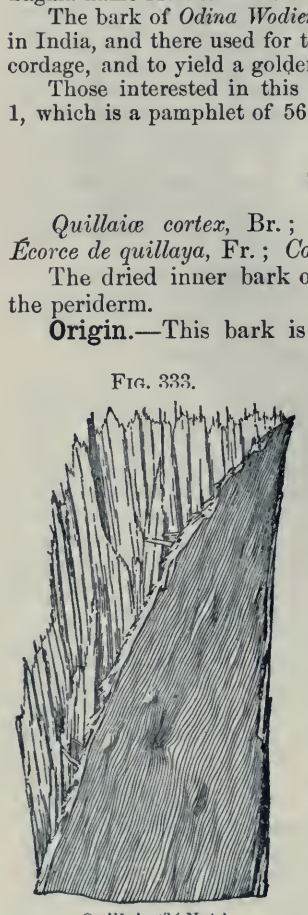
QUILLAJA, *U. S.*—Quillaja.

Quillaiæ cortex, Br.; *Cortex Quillaiæ*, P. G.—*Soap-bark*, E.; *Seifenrinde*, G.; *Écorce de quillaya*, Fr.; *Corteza de quillaya, Quillaya*, Sp.

The dried inner bark of *Quillaja Saponaria* Molina (Fam. *Rosaceæ*), deprived of the periderm.

Origin.—This bark is collected from a very large tree growing in and near the coast region of central and northern Chile. The bark is imported in bales, packed under hydraulic pressure.

Fig. 333.



Quillaja (¾ Nat.).

Description.—In large, flat pieces, 3 to 8 Mm. (⅛–⅓ In.) thick; outer surface brownish white, often with larger or smaller patches of the dark-brown outer layer adhering, otherwise smoothish or lightly striate; inner surface pale yellowish or whitish, nearly smooth, or often with longitudinally elongated blister-like elevations; fracture tough and strongly splintery, the laminæ oblique to each other; transverse section checkered with pale-brownish bast-fibers imbedded in the white tissue; inodorous, but the powder highly sternutatory; taste persistently acrid.

The infusion foams like soap-water.

Constituents.—The active portion of soap-bark consists of about 9 per cent. of an amorphous substance commonly denominated "saponin," but which is in reality a mixture of two glucosidal bodies better known as *quillajic acid* and *quillajasapotoxin*. Kobert recommends the extraction and separation of these two saponin bodies in the following manner: A decoction of quillaja bark is filtered and concentrated, then saturated with ammonium sulphate, boiled for some minutes, and again filtered. The resulting precipitate contains the quillajic acid and the coloring-matter of the bark, while the colorless filtrate will contain the quillajasapotoxin. In order to recover the quillajic acid, the precipitate is expressed and treated repeatedly with boiling alcohol, the alcoholic solutions are united and filtered, and to the clear fil-

trate, when cool, ether is finally added, which precipitates the acid in the form of a white, flocculent mass. The quillajasapotoxin is obtained from the colorless filtrate above mentioned by concentrating the same, adding an excess of alcohol, removing the newly separated ammonium sulphate, filtering, and adding ether, which precipitates the sapotoxin in the form of a white powder. In place of the above method, the two bodies may be separated by means of neutral and basic lead acetates, but the latter process is more laborious (see separate article on SAPONINS). Soap-bark is noted for its large content of crystals, chiefly of calcium sulphate, partly of calcium oxalate.

Quillajic acid, $C_{19}H_{30}O_{10}$, is a weak amorphous acid, forming also amorphous salts. It is readily soluble in water, solutions of caustic, and carbonated alkalies, and in alcohol and methyl alcohol, but very difficultly soluble in chloroform and insoluble in ether. Its aqueous solution foams considerably when shaken, and changes the color of blue litmus-paper to red, and that of congo red to blue. Quillajic acid is precipitated by both neutral and basic lead acetate, differing in this respect from the other saponin body met with in soap-bark. After boiling with diluted mineral acids it yields dextrose, but it is not affected by ptyalin, pancreatin, and diastase. It is strongly sternutatory and has an acrid taste, but, according to Kobert, does not possess these properties if it has been purified by acetylization or been treated with barium hydroxide.

Quillajasapotoxin, $C_{17}H_{26}O_{10}$, frequently designated simply as *sapotoxin*, occurs as an amorphous neutral substance, soluble in water, warm diluted alcohol, and solutions of caustic and carbonated alkalies, but difficultly soluble in alcohol, and almost insoluble in chloroform; somewhat soluble in a mixture of 1 part of absolute alcohol and 4 parts of chloroform. It is insoluble in ether and difficultly soluble in methyl and amyl alcohol. Its aqueous solution foams strongly when agitated, and prevents sedimentation of finely divided matter added thereto. Quillajasapotoxin has a somewhat mild taste, which soon becomes acrid and burning, and is intensely irritating and sternutatory. It is not affected by neutral lead acetate, but is precipitated by the basic acetate. It is decidedly toxic and exercises a solvent effect on red blood-corpuscles.

Pharmaceutical Preparations.—FLUIDEXTRACT OF QUILLAJA, TINCTURE OF QUILLAJA, U. S. P.

Action and Uses.—Quillaja has been recommended as a substitute for senega in subacute and chronic bronchitis. It is stimulating to the bronchial mucous membrane, and relieves cough by causing dislodgement of tenacious mucus from the walls of the bronchi. The bark in powder produces sneezing, and has been used as a snuff with asserted good results in chronic rhinitis. In infusions of varying strength it is employed as a detergent in place of soap to cleanse the scalp when it is affected with ulcers or eruptions.

Allied Products.—In the Philippines the bark of *Entada scandens* (L.) Benth. (*Mimosa s.*—L.) is employed under the name *Gogo*, and in Java under the name *Gandoo*, for the same purposes as soap-bark, its constituents being evidently very similar. The seeds of this plant constitute one of the several products known as *Sea bean* or *Faba marina*.

The number of drugs and other active vegetable substances, many of them used as fish poisons, which contain acrid, sternutatory, and poisonous substances foaming with water, and to which the name saponin has been applied, is large, and very many of them have been referred to in this work, especially in our articles on CARYOPHYLLACEÆ and other families.

QUINIDINÆ SULPHAS.—Quinidine Sulphate.

Sulfate de quinidine basique, Fr. Cod.; *Chinidinum (Conchininum) sulfuricum.*—*Sulphate of conquinine*, E.; *Sulfate de quinidine*, Fr.; *Schwefelsaures Chinidin, Conchininsulfat*, G.

Formula, $(C_{20}H_{24}N_2O_2)_2H_2SO_4 + 2H_2O$. Molecular weight, 776.75.

The neutral sulphate of an alkaloid obtained from the bark of several species of cinchona. Quinidine sulphate should be kept in well-stoppered bottles in a dark place.

Preparation.—The mother-liquors from the recrystallization of quinine sulphate yield on concentration a crop of crystals consisting chiefly of this salt, which is purified by treatment with animal charcoal and by recrystallizing it. On adding to the mother-liquors a considerable excess of ammonia, cinchonine will be precipitated and quinidine dissolved; the solution deposits the alkaloid quinidine, together with impurities, on the

addition of soda. The alkaloid may then be dissolved in dilute sulphuric acid, and the salt purified by recrystallization. Since quinidine enters the mother-liquors containing the amorphous alkaloids, and is precipitated with chinoidine, it may be prepared from the latter, according to Hesse (1868), by exhausting it with ether, converting the dissolved alkaloids into sulphates, precipitating quinine and cinchonidine with Rochelle salt, purifying the filtrate with animal charcoal, and precipitating the quinidine with potassium iodide; the alkaloid is then liberated by ammonia, combined with sulphuric acid, and the salt crystallized.[1]

Quinidine is an isomer of quinine, which it closely resembles in the fluorescence of its solutions, and in the thalleioquin reaction, as well as in its physiological properties. It is, however, distinguished from QUININE (which see) in being dextrogyre ([a]. = + 236.77° in 97 per cent. alcohol, Hesse). It crystallizes from boiling water as non-efflorescent permanent plates with 1½ molecules of water, from ether as rhombohedra, and from alcohol with 2½ molecules of water as lustrous monoclinic prisms or needles, which are efflorescent, but do not lose all their water of crystallization under 120° C. (248° F.). It melts at 168° C. (334.4° F.). Quinidine is soluble in 2000 parts of water at 15° C. (59° F.), in 750 parts of boiling water, in 22 parts of ether at 20° C. (68° F.), and readily soluble in hot chloroform and amyl alcohol.

Properties.—Quinidine sulphate crystallizes in white, silky needles which resemble those of the quinine salt, but are less matted and do not effloresce on exposure even when heated to 80° C. (176° F.); when heated to 120° C. (248° F.) they part with their water of crystallization (4.6 per cent.), and on ignition are entirely consumed. The solution in dilute sulphuric acid shows the blue fluorescence of quinine solutions, and strikes an emerald-green color on the successive addition of chlorine-water and ammonia, and a red color in the successive addition of chlorine-water, potassium ferrocyanide, and ammonia. The salt has also, like the corresponding quinine salt, a very bitter taste and a neutral reaction. It dissolves at 10° C. (50° F.) in 108 parts (Hesse), at 15° C. (59° F.) in 110 parts (Fr. Cod.), and at the boiling-point in 10 parts of water; at 15° C. (59° F.) also soluble in 8 parts of alcohol and 19.5 parts of chloroform, and in 10 parts of boiling chloroform. It is very soluble in boiling alcohol and nearly insoluble in ether.

FIG. 334.

Quinidine Sulphate with KSCy: microscopic crystals.

The chloroform solution on evaporation leaves the salt in an amorphous state, and on exposure to diffused daylight gradually acquires a green color, but the alkaloid is not perceptibly affected thereby (Hesse, 1879). The aqueous solution yields with barium chloride a white precipitate which is insoluble in hydrochloric acid; with potassium ferrocyanide golden-yellow prisms or a yellow crystalline precipitate; and with potassium iodide from neutral solution, a white, and from acid solution a reddish-yellow, crystalline precipitate. Potassio-cadmic-iodide (Marme's reagent) added to dilute solutions of quinidine yields tufts of microscopic crystals which are markedly different from those of the other quinine alkaloids (Vreven). When a drop of the solution is mixed with a drop of solution of potassium sulphocyanate, the microscope reveals groups of radiating feathery crystals; this quinidine sulphocyanate requires 1477 parts of water for solution.

Tests.—When heated on platinum-foil the salt should burn without leaving any residue. The thalleioquin test may be applied as follows: On treating 10 Cc. of an aqueous solution (about 1 in 1600) of the salt with 2 drops of bromine-water, and then with an excess of ammonia-water, the liquid will acquire an emerald-green color. With proper adjustments of the reagents, more dilute solutions will show a paler tint, while more concentrated ones will acquire a deeper color or deposit a green precipitate. De Vrij's (1878) test is applied as follows: A cold saturated, aqueous solution of the salt yields a white precipitate with potassium iodide test-solution (difference from quinine sulphate); dissolved in 50 Gm. of hot water, and 0.5 Gm. potassium iodide added, a

[1] The alkaloid *quinidine* was first isolated as a pure base by Van Heijningen (1848). In the literature antedating 1877 much confusion exists as to the name for this alkaloid. The term quinidine of the present day is synonymous with the β-quinine of Heijningen (1849), the β-quinidine of Kerner (1862), and Hesse's (1874) conchinine, as well as chinotin, cinchotin, conquinine, pitayin, and crystallized chinoidin.

sandy crystalline precipitate must fall, and after some hours the mother-liquor, on being tested with ammonia, should not produce an appreciable precipitate. Quinidine sulphate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of readily carbonizable organic impurities) nor produce a red color with nitric acid (difference from morphine). If a small quantity of ammonia-water be added to 3 Cc. of an aqueous solution of the salt saturated at 15° C. (59° F.), a white precipitate (quinidine) will be produced, which requires more than 30 Cc. of ammonia or more than thirty times its weight of ether to dissolve it (absence of more than small proportions of other cinchona alkaloids). 0.5 Gm. should dissolve clear in 10 Gm. of chloroform.

Action and Uses.—The sulphate and other salts of quinidine may be substituted for those of quinine. They are less powerful than the quinine salts, and must be administered in larger quantity. The antiperiodic dose of the sulphate is from 10 to 60 grains (0.60–4 Gm.).

Allied Salts.—QUINIDINÆ BISULPHAS, *Acid quinidine sulphate*, $C_{20}H_{24}N_2O_2.H_2SO_4 + 4H_2O$. It is obtained by dissolving the sulphate in sufficient diluted sulphuric acid and evaporating. It forms long colorless prisms of an asbestos-like appearance, soluble in 8.7 parts of water at 10° C. (50° F.) and losing 14.57 per cent. of water at 120° C. (248° F.).

QUINIDINÆ HYDRIODIDUM, *Quinidine hydriodide*, $C_{20}H_{24}N_2O_2HI$. It is obtained by double decomposition of neutral solutions of quinidine sulphate and potassium iodide as a white crystalline powder, or from warm and somewhat diluted solutions in colorless scaly prisms. It is slightly soluble in alcohol and in hot water, and requires at 10° C. (50° F.) 1270 parts of water for solution. The salt is anhydrous and contains 28.09 per cent. of iodine.

QUINIDINÆ HYDRIODIDUM ACIDUM, *Acid quinidine hydriodide*, $C_{20}H_{24}N_2O_2(HI)_2 + 3H_2O$. It is prepared like the preceding salt, using, however, a warm acidulated solution of quinidine sulphate. It forms an orange-colored crystalline powder or glossy golden-yellow prisms, turns brown yellow at 120° C. (248° F.) from loss of water, which is absorbed again on exposure to moist air, and is soluble in 90 parts of cold water, and more freely soluble in alcohol and in hot water. The salt contains 8.5 per cent. of water and 43.77 per cent. of iodine.

QUINIDINÆ HYDROCHLORIDUM, *Quinidine hydrochloride*, $C_{20}H_{24}N_2O_2.HCl + H_2O$. It is prepared by dissolving 10 parts of quinidine in about 200 parts of water and 4.5 parts of 25 per cent. hydrochloric acid and crystallizing the salt. It forms asbestos-like fibres, which are soluble in about 50 parts of water at 15° C. (59° F.), readily soluble in alcohol, but almost insoluble in ether.

QUININA.—*U. S.*—Quinine.

Chininum.—Quinine, Fr.; *Chinin*, G.

Formula, $C_{20}H_{24}N_2O_2 + 3H_2O$. Molecular weight, 375.46.

An alkaloid obtained from the bark of various species of Cinchona. Quinine should be kept in well-stoppered bottles in a dark place.—U. S.

Preparation.—On precipitating a solution of quinine sulphate in acidulated water with an alkali, a curdy, amorphous, white precipitate is obtained, consisting of the anhydrous alkaloid, which if kept under the liquid is gradually changed to the crystalline hydrate of the above formula. It requires to be washed with distilled water and dried at a low temperature. The same hydrate may also be obtained from the solution of the alkaloid in diluted alcohol by crystallizing at a low temperature, while at 30° C. (86° F.) silky needles of anhydrous quinine are separated (Hesse). On concentrating a solution of quinine in ammonia-water the hydrate crystallizes. The precipitation of quinine should be effected without heat, and only a slight excess of ammonia should be used to prevent loss of the alkaloid.

Properties.—Quinine occurs as a white, flaky, or micro-crystalline powder, odorless, having a bitter taste, and slightly efflorescent in dry air. Quinine, when freshly crystallized, should contain 3 molecules of water of crystallization. When heated, it fuses at 57° C. (134.6° F.), and loses 2 molecules of water of crystallization at 100° C. (212° F.), and the third molecule at 125° C. (257° F.); at ordinary temperatures the loss is gradual. Quinine free from water is soluble in 1750 parts of water, 0.6 part of alcohol, 4.5 parts of ether, 1.9 parts of chloroform, 158 parts of glycerin, 120 parts of benzene, 3450 parts of a solution of potassium hydroxide (1 in 20), and in 1810 parts of ammonia-water at 25° C. (77° F.). It is soluble in 810 parts of water at 80° C. (176° F.). Quinine containing 3 molecules of water is soluble in 1550 parts of water, 0.6 part of alcohol, 1.3 parts of ether, 1.6 parts of chloroform, 212 parts of glycerin, 166 parts of benzene, 3450 parts of a solution of potassium hydroxide (1 in 20), and in 1810

parts of ammonia-water at 25° C. (77° F.). It is soluble in 775 parts of water at 80° C. (176° F.). When rendered anhydrous by heating to constant weight at 125° C. (257° F.), its melting-point is 174.9° C. (346.8° F.). It is lævogyrate, and is alkaline to moistened litmus-paper. If to 1 Cc. of an aqueous solution of quinine (1 in 100), containing just sufficient diluted sulphuric acid to effect complete solution, there be added 2 Cc. of bromine test-solution, followed by 1 Cc. of ammonia water, the liquid should acquire an emerald-green color (thalleioquin). If 0.7 Gm. of quinine be dissolved in a mixture of 15 Cc. of acetic acid, 6 Cc. of alcohol, and 0.5 Cc. of sulphuric acid, the solution heated to boiling, and 7 Cc. of a saturated solution of iodine in alcohol be added slowly, bronze or olive-green crystals of quinine iodo-sulphate will separate on gradually cooling the solution. These crystals are insoluble in cold water. If 0.2 Gm. of quinine be dissolved in 1 Cc. of diluted sulphuric acid, the solution diluted with distilled water to 20 Cc. and neutralized with ammonia-water, and 1 drop of solution of hydrogen dioxide and 1 drop of copper sulphate test-solution be added, and the liquid boiled, an intensely red color should appear, which slowly changes to a blue, and finally to a green color. (Quinine and quinidine alone respond to this test.)—U. S.

Quinine is a strong base, neutralizes the strongest acids, forming crystallizable salts, which, if soluble, have an intensely bitter taste, and displaces ammonia from its salts on being heated with their solutions. The crystals are alkaline to litmus and turmeric, but not to phenolphthalein. Its salts of 2 molecules of base and 1 of acid are neutral to Brazil wood, cochineal, and logwood, but strongly alkaline to methyl orange. The bisulphate is neutral to the latter indicator. The acidulated solutions show a vivid blue fluorescence, which disappears on the addition of hydrochloric, hydriodic, and sulphocyanic acids and of thiosulphates. The fluorescence is also prevented in dilute solutions by the presence of acetphenetidin, which latter may also cause a blue color to appear, instead of green, in the thalleioquin test.

Solutions of the alkaloids, as such, in neutral solvents, exposed to sunlight develop a brown color and lose their alkaloidal character through the formation of *quiniretin* (Flückiger). Quinine, on treatment with permanganate, chromic acid, nitric acid, etc., yields various oxidation products, according to conditions—formic acid HCO_2H, quitonine $C_{19}H_{22}N_2O_4$, cincholeupone $C_9H_{17}NO_2$, cincholeuponic acid, quinic acid, and cinchomeronic acid $C_5H_3N(COOH)_2$ being among the products. When fused with potassium hydroxide, quinine yields methoxyquinoline, $C_9H_6N(OCH_3)$. Quinine is considered to be a derivative of hydro-diquinoline.

Quinine heated with glycerin to about 190° C. (374° F.) is converted into the isomeric base *quinicine*, which was discovered by Pasteur (1853), and may be obtained from most acid quinine salts by heating them to about 130° C. (266° F.). Quinicine is amorphous (difference from quinine and cinchonidine), dextrogyre, difficultly soluble in water, readily soluble in alcohol, and forms with acids crystallizable salts which are colored green by chlorine-water and ammonia, and yield with hypochlorites white precipitates which are turned green by ammonia.

Tests.—Quinine should not impart more than a faintly yellowish tint to sulphuric acid (limit of really carbonizable organic impurities), nor produce a red color with nitric acid (difference from morphine). 1 Gm. of quinine should dissolve completely in a slightly warmed mixture of 6 Cc. of absolute alcohol and 3 Cc. of ether, which solution should remain clear on cooling (absence of cinchonine and cinchonidine). Quinine should not lose more than 14.3 per cent. of water on heating to 125° C. (257° F.) (absence of an excess of water). When heated with 2 Cc. of potassium hydroxide test-solution, no ammonia should be evolved (absence of ammonium salts). Dissolve 2 Gm. of quinine, which has previously been dried at 50° C. (122° F.) for two hours in a porcelain dish, in 20 Cc. of alcohol. Add 2 drops of hematoxylin test-solution, neutralize exactly with sulphuric acid, and evaporate to dryness on a water-bath. Complete the test by following the directions given on page 1296, under QUININÆ SULPHAS (Test for Other Cinchona Alkaloids, Section II.).—U. S.

Action and Uses.—Quinine and its salts possess a very bitter taste, and are capable, in concentrated form, of causing gastric irritation, and on elimination, some irritation of the bladder. When taken in full medicinal dose it causes a sense of fullness in the head and dizziness, ringing in the ears, some impairment of hearing, and even disorders of taste and smell. In those who are very susceptible to its effects it may cause blindness, and those who suffer from middle-ear disease may be made completely deaf by its use. In small medicinal doses it acts as a bitter tonic upon the gastric mucous

membrane and as a feeble nervous stimulant or tonic. Upon the blood in medicinal doses it produces in health no changes whatever, but in very large doses it probably prevents the out-wandering of white blood cells, known as diapedesis. If taken for any considerable period of time, it increases the number of red blood corpuscles. Its effect upon respiration is very slight. Upon body temperature it exercises no influence in health, and is a feeble antipyretic in disease, except in malarial fever, when it has a specific influence upon the malarial parasite. The drug is entirely absorbed by the stomach, and if it enters the intestine is precipitated by the alkaline juices of that part of the alimentary canal, although after precipitation it is possible that small quantities are slowly absorbed. Quinine escapes chiefly through the kidneys, but a large part of it is oxidized and destroyed by the tissues of the body. It diminishes tissue waste.

When poisonous doses are taken it not only produces the symptoms already named, but also deep coma, superficial breathing, a slow pulse, and absolute loss of hearing and sight. Very few cases of serious poisoning from its use have, however, been reported. On the other hand, few drugs are so frequently followed by untoward effects when taken by susceptible individuals. In addition to the symptoms named which sometimes follow a medicinal dose, it not rarely produces various forms of skin eruption, most commonly of the nature of erythema or urticaria. Occasionally, vesicles and petechiæ are present. Many of the disagreeable symptoms which are felt in the head can be avoided, when large doses are necessary, by the simultaneous administration of 10 or 20 grains of bromide of sodium with 15 minims of the fluidextract of ergot. Occasionally, in old cases of chronic malarial cachexia, the use of quinine seems to produce hemiglobinuria. Strangury due to irritation of the neck of the bladder is sometimes caused by its use.

Quinine is used in medicine for three chief purposes: First, and most important, for its anti-malarial influence, which it exercises by virtue of its power over the malarial parasite, which it destroys in so small a proportion of blood as 1 to 20,000. When used to combat malarial infection, it may be employed as a preventive and as a cure. Patients exposed to malarial infection should take from 3 to 5 grains daily to prevent the development of the disease. In patients who have already become infected, the method of its administration depends somewhat upon the type of the parasite. When it is due to the presence of the tertian or quartan parasite, the quinine may be given in soluble form—that is, in freshly made pill, capsule, or solution—every hour for 3 or 4 hours before the expected paroxysm. If the drug is preceded by calomel, so that the liver is rendered active at the time of its absorption, it is very much more efficacious than if the liver is torpid. Ordinarily, doses of from 5 to 20 grains, given at the intervals named, are quite sufficient. Smaller doses are required if the patient will keep to his bed than if he persists in moving about. Certain practitioners prefer to administer the quinine not several hours before the paroxysm, with the object of aborting the oncoming attack, but during or a short time before the paroxysm, in order that the drug may destroy the parasite when sporulation occurs during the attack of chill and fever, since by this means the young parasites are killed before they can attack other red cells. If a patient suffering from a malarial paroxysm is seen, therefore, as late as the sweating stage, the administration of full doses of quinine will do much toward preventing a subsequent attack. It is of great importance to remember that the introduction of quinine into a stomach which is atonic and torpid will not be followed by good results, since the drug will not be absorbed with sufficient rapidity to enter the blood and destroy the parasite. The calomel treatment already advised is, therefore, necessary in most cases, and the absorption of quinine can be hurried by giving a hot drink with it, or by administering to the patient a few drops of hydrochloric acid, which will aid in its solution and absorption. In bilious remittent fever which is due to the æstivo-autumnal parasite, the condition of the stomach and liver is usually so grave that active treatment must be devoted to these two organs, and quinine can do little good unless they are fit to aid in its entrance into the blood. Under these circumstances the drug should be given in hourly doses, in larger quantities than are necessary in the infection by tertian and quartan parasites. In severe cases of æstivo-autumnal infection, when the infection is pernicious in character, it may be advisable to give the quinine intravenously, employing a vein in the leg for the injection, so that the drug will not go to the heart in a concentrated form, under which circumstances it is a depressant to this viscus. 10 to 15 grains is as much as should be given in this manner at a single dose. The injection is prepared by dissolving 15 grains of quinine hydrochloride with 15 grains of sodium chloride in an ounce and a half of sterile, distilled water or in normal salt solution. In certain forms

of severe neuralgia depending upon malarial infection quinine is a very valuable remedy. Its use in typhoid and other fevers as an antipyretic is practically valueless, since large doses are prone to disorder the stomach, and small doses cannot exercise any effect upon the fever. Further than this, the fever is bound to run its course whether quinine is given or not. Although the drug was employed quite largely at one time as an antipyretic in non-malarial diseases, this use of it has become almost obsolete, because of the introduction of the more powerful coal-tar antipyretics, and because of its innate feebleness.

As a bitter tonic during convalescence from any one of the acute infectious diseases, in the dose of from 1 to 5 grains, twice or thrice a day, it is a valuable drug.

Among the other uses of quinine may be mentioned its employment to overcome uterine inertia in feeble women; but for this purpose a cup of strong coffee, a hypodermic injection of strychnine, or the internal use of the fluidextract of kola or coca is much more advantageous. It has been claimed by obstetricians of experience that the use of quinine in labor predisposes the patient to postpartum hemorrhage. The idea that it is capable of causing abortion when given in medicinal dose is incorrect, unless perchance the patient is one who is prone to abort.

Quinine, in moderate dose, is a useful "support" to the general system in the pneumonia of children and during mental or physical strain in adults. It also has a reputation of being of value as a prophylactic against the infection which causes whooping-cough. Under these circumstances it is much more efficacious if taken into the mouth in solution or if sprayed into the pharynx than if swallowed in pill form. In the strength of 1 : 3000 quinine may be injected into the colon in cases of amœbic dysentery, as it is capable of destroying the Amœba coli.

Administration.—The best salt of quinine for ordinary uses is the hydrochloride, because it is very soluble. Next, in this advantage, is the hydrobromide, while the most insoluble are the sulphate and tannate, both of which salts have a lower alkaloidal strength. The bisulphate is also frequently employed.

Because of its bitter taste quinine is commonly given in pill or capsule. It ought not to be used in compressed tablets or in the form of old pills, since these are difficult of solution, and often pass into the bowel before being dissolved, and thereby the patient loses the full medicinal effect of the doses given. In the administration of quinine to children it may be mixed with chocolate and licorice, and the tannate of quinine may be employed because its insolubility renders it less bitter than the more soluble forms. When quinine is to be used in suppositories, the best salt to employ is the hydrochloride.

UNOFFICIAL SALTS OF QUININE.

Quininæ Acetas. *Quinine acetate.* $C_{20}H_{24}N_2O_2.HC_2H_3O_2$.—Quinine acetate crystallizes in long white needles, and is soluble in about 600 parts of water at 15° C. (59° F.), in 20 parts of hot water, and in 7 parts of alcohol. It contains 84.38 per cent. of quinine and 15.62 per cent. of acetic acid. When crystallized from a solution containing excess of acetic acid the neutral quinine acetate $C_{20}H_{24}N_2O_2.2(HC_2H_3O_2).3H_2O$ is obtained, which contains 65.06 per cent. of quinine.

Quininæ Arsenas. *Quinine arsenate.* $2(C_{20}H_{24}N_2O_2).H_3AsO_4 + 8H_2O$.—This salt is obtained by precipitating a solution of 10 parts of quinine hydrochloride, dissolved in 200 parts of warm water, with a solution of 3.9 parts of sodium arsenate dissolved in 100 parts of water. The precipitate is washed with cold water and recrystallized from hot water. It occurs as long white prisms, difficultly soluble in cold water, readily soluble in hot water. It contains 69.39 per cent. of quinine and 12.30 per cent. of arsenic acid. It is given in the dose of from 1 to 3 grains (0.06–0.20 Gm.).

Quininæ Arsenis. *Quinine arsenite.* $3(C_{20}H_{24}N_2O_2).H_3AsO_3 + 4H_2O$.—The salt is prepared by boiling 5 parts of silver arsenite and 11.3 parts of quinine hydrochloride with 100 parts of 70 per cent. alcohol, under a reflux condenser, until the transposition is complete, filtering, and crystallizing the salt from the clear filtrate. Silky white needles, sparingly soluble in cold water, soluble in about 150 parts of boiling water, in 15 parts of cold and 6 parts of boiling alcohol, in 8 parts of chloroform, in 25 parts of ether, and in 20 parts of benzene. The salt contains 83.08 per cent. of quinine and 8.45 per cent. of arsenous acid.

Quininæ Benzoas. *Quinine benzoate.* $C_{20}H_{24}N_2O_2.C_7H_6O_2$.—This salt is obtained by dissolving 3 parts of benzoic acid and 8 parts of quinine (anhydrous) in hot alcohol and crystallizing. It forms small prisms containing 72.65 per cent. of quinine and 27.35 per cent. of benzoic acid. It requires 373 parts of water at 10° C. (50° F.) for solution.

Quininæ Boras. *Quinine borate.* $C_{20}H_{24}N_2O_2.BO_3H_3$.—It is prepared by evaporating a mixture of 10 parts of anhydrous quinine and 1.91 parts of boric acid with 20 parts of water and pulverizing the dry residue. It contains 83.95 per cent. of quinine and 16.05 per cent. of boric acid.

Quininæ Bromas. *Quinine bromate.* $C_{20}H_{24}N_2O_2.HBrO_3$.—It is prepared by C. A. Cameron (1882) either by neutralizing quinine with bromic acid or by precipitating barium bromate with quinine sulphate. It forms asbestos-like masses consisting of long needles, dissolves in 250 parts of cold water, freely in warm water, in diluted acids, and in alcohol; it is not decomposed at a moderate heat, but detonates in contact with strong sulphuric acid.

Quininæ Camphoras. *Quinine camphorate.* $2(C_{20}H_{24}N_2O_2).C_{10}H_{16}O_4$.—The salt is obtained by evaporating and crystallizing an alcoholic solution of 10 parts of camphoric acid and 32.4 parts of anhydrous quinine. A white powder, insoluble in water, but soluble in alcohol. It contains 76.41 per cent. of quinine.

Quininæ Carbolas. *Quinine carbolate, Quinine phenate.* $C_{20}H_{24}N_2O_2.C_6H_6O$.—The salt is obtained by dissolving 34.4 parts of quinine (anhydrous) in 100 parts of alcohol and adding 10 parts of crystallized carbolic acid and crystallizing. Delicate white needle-shaped crystals, soluble in 400 parts of water, in 80 parts of alcohol, and contain 77.52 per cent. of quinine.

Quininæ Carbonas. *Quinine carbonate.* $C_{20}H_{24}N_2O_2.H_2CO_3 + H_2O$.—Freshly precipitated quinine is suspended in water and a current of washed carbonic acid gas passed through the mixture until all the quinine is dissolved, and the solution allowed to evaporate and crystallize. Fine needle-shaped crystals, soluble in water and alcohol, and effervesce with acids. It is apt to decompose on keeping. The salt contains 80.2 per cent. of quinine.

Quininæ Chloras. *Quinine chlorate.* $C_{20}H_{24}N_2O_2.HClO_3 + 1\frac{3}{4}H_2O$.—This salt is prepared by allowing molecular quantities of quinine sulphate and barium chlorate to react upon each other in hot aqueous solution and crystallizing the filtered liquid. White crystalline needles or tufts, sparingly soluble in cold water, soluble in hot water, and emit chlorine on addition of hydrochloric acid. It contains 73.66 per cent. of quinine.

Quininæ Chlorhydrophosphas. *Quinine chlorhydrophosphate.* $C_{20}H_{24}N_2O_2.HCl\text{-}2[H_3PO_4] + 3H_2O$.—This salt is obtained in a crystalline form by dissolving 35 parts of quinine hydrochloride in a mixture of 70 parts of phosphoric acid (25 per cent.) and 9 parts of hydrochloric acid (12.5 per cent.) and allowing the salt to crystallize upon spontaneous evaporation of the liquid. The crystals are soluble in 2 parts of water, have an acid reaction, and contain 53.08 per cent. of quinine, 5.96 per cent. of hydrochloric acid, 32.1 per cent. of phosphoric acid, and 8.84 per cent. of water.

Quininæ Chlorhydrosulphas. *Quinine chlorhydrosulphate.* $[C_{20}H_{24}N_2O_2]_2H_2SO_4\text{-}2HCl + 3H_2O$.—This salt is prepared by dissolving 10 parts of quinine sulphate in 3.3 parts of hydrochloric acid (25 per cent.) and letting the solution crystallize by spontaneous evaporation of the liquid. Colorless crystals, soluble in 1 part of water, and giving reactions for chloride and sulphate with test reagents. It contains 74.24 per cent. of quinine, 11.22 per cent. of sulphuric acid, and 8.54 per cent. of hydrochloric acid.

Quininæ Chromas. *Quinine chromate.* $C_{20}H_{24}N_2O_2.H_2CrO_4 + 2H_2O$.—The salt may be prepared by dissolving 4 parts of quinine hydrochloride in 100 parts of warm water and precipitating it with a solution of 1 part of neutral potassium chromate dissolved in 15 parts of water. The precipitate is washed free from chloride and recrystallized from hot dilute alcohol. Yellow crystalline needles, soluble in 2433 parts of water at 12° C. (53.6° F.), in 2000 parts at 16° C. (60.8° F.), and 160 parts of boiling water.

Quininæ Citras. *Quinine citrate.* $(C_{20}H_{24}N_2O_2)_2.C_6H_8O_7 + 7H_2O$.—The salt may be prepared by adding 3.086 parts of quinine (anhydrous) to a boiling solution of 1 part of crystallized citric acid in 100 parts of water and heating, a clear solution is obtained, which is then filtered and allowed to cool and crystallize. Quinine citrate occurs as white crystalline needles, which are soluble in 900 parts of cold water, in 30 parts of boiling water, in 3 parts of boiling alcohol, and 45 of cold alcohol. Quinine citrate contains 67.08 per cent. of quinine.

Quininæ Ferrocyanidum. *Quinine ferrocyanide.* $C_{20}H_{24}N_2O_2.Fe(CN)_6H_4 + 2H_2O$.—This salt may be prepared by mixing alcoholic solutions of 10 parts of quinine (anhydrous) and 6.66 parts of hydroferrocyanic acid and allowing the salt to crystallize. It occurs as yellow crystalline needles, having a bitter taste. The salt is difficultly soluble in water, but readily soluble in hot alcohol. It contains 56.25 per cent. of quinine.

Quininæ Glycerophosphas. *Quinine glycerophosphate.* $[C_{20}H_{24}N_2O_2]_2PO_4H_2(C_3H_5O_2) + 4H_2O$.—This salt may be obtained by neutralizing quinine with the necessary equivalent of glycerophosphoric acid and crystallizing the product. It may also be prepared by adding a solution of 34.8 parts of quinine hydrochloride in 1000 parts of water to a solution of 10 parts of calcium glycerophosphate. The precipitate is washed and crystallized. Odorless white crystalline needles, having a bitter taste, and are soluble in about 200 parts of boiling water, in 100 parts of cold water, and readily soluble in hot alcohol and glycerin. The crystals melt at 154° C. (309.2° F.), and contain 72.36 per cent. of quinine. For other

QUININE GLYCEROPHOSPHATES, see Proc. A. P. A. 46, p. 1056. This salt is used as a tonic in nervous exhaustion in the dose of from 2 to 5 grains (0.12–0.30 Gm.).

Quininæ Hydriodidum. *Quinine hydriodide.* $C_{20}H_{24}N_2O_2.HI$.—This salt may be prepared by precipitating a solution of 10 parts of quinine hydrochloride in 250 parts of hot water with a solution of 6 parts of potassium iodide in 15 parts of water, washing the precipitate, and drying it at a gentle heat in a dark place. The salt is difficultly soluble in cold water, but soluble in hot water, alcohol, and ether. It contains 71.71 per cent. of quinine.

Quininæ Hydriodidum Acidum. *Acid quinine hydriodide.* $C_{20}H_{24}N_2O_2(HI)_2.5H_2O$.—This salt crystallizes from a warm acidulated solution of quinine on the addition of potassium iodide. It forms glossy transparent prisms or scales, becomes opaque at 30° C. (86° F.), melts at 100° C. (212° F.) in its water of crystallization, and becomes completely anhydrous at 120° C. (248° F.); when exposed to a damp atmosphere the anhydrous salt combines again with $2H_2O$ (Hesse, 1865).

Quininæ Hypophosphis. *Quinine hypophosphite.* $C_{20}H_{24}N_2O_2.H_3PO_2$.—This salt may be prepared by mixing a solution of 25 parts of quinine sulphate dissolved in 400 parts of alcohol with a solution of 5 parts of calcium hypophosphite dissolved in 100 parts of water. After standing about 1 hour the solution is filtered, concentrated, and crystallized. Colorless prisms, soluble in alcohol, in 15 parts of boiling water, and in 70 parts of cold water. This salt is more stimulating than the other hypophosphites, and is an ingredient of many compound syrups and solutions of these salts. The dose is from 1 to 5 grains (0.06–0.30 Gm.).

Quininæ Iodas. *Quinine iodate.* $C_{20}H_{24}N_2O_2.HIO_3$.—Quinine iodate, according to C. A. Cameron (1882), is best prepared by digesting freshly precipitated quinine in a molecule of iodic acid previously dissolved in 10 parts of warm water; the soft mass should be evaporated at 15.5° C. (60° F.) and dried over sulphuric acid. The salt is in minute white pearly needles, is readily soluble in alcohol, soluble in 700 parts of cold water, and is not decomposed by boiling water. It contains 62.82 per cent. of quinine.

Quininæ Lactas. *Quinine lactate.* $C_{20}H_{24}N_2O_2.C_3H_6O_3$.—This salt is prepared by neutralizing quinine with the necessary equivalent of lactic acid in hot aqueous solution, and evaporated at a temperature not exceeding 60° C. (140° F.) and crystallized. Colorless prismatic needles, soluble in 3 parts of cold water, in about 1 part of boiling water, readily soluble in ether. It contains 78.26 per cent. of quinine.

Quininæ Phenylsulphonas. *Quinine phenolsulphonate, Quinine sulphocarbolate.* $C_{20}H_{24}N_2O_2.(C_6H_4[OH]SO_3H)$.—This salt may be prepared by adding a hot solution of 10 parts of quinine sulphate dissolved in 500 parts of water to a boiling solution of 6 parts of barium phenolsulphonate dissolved in 75 parts of water. The resulting precipitate is washed and dried. It is a yellowish-white resinous mass, melting on the application of heat, is difficultly soluble in water, but soluble in alcohol. It contains 65.06 per cent. of quinine.

Quininæ Phosphas. *Quinine phosphate.* $(C_{20}H_{24}N_2O_2)_2.H_3PO_4.8H_2O$.—Quinine phosphate may be prepared by dissolving quinine in warm dilute phosphoric acid or by decomposing quinine hydrochlorate with sodium phosphate. It crystallizes from hot water in long silky needles, which require at 10° C. (50° F.) 784 parts of water for solution, and contain 72.81 per cent. of quinine.

Quininæ Sulphovinas. *Quinine sulphovinate.* $C_{20}H_{24}N_2O_2.SH(C_2H_5)O_4$.—Carles (1878) prepares the neutral salt by dissolving 16.6 parts of sodium sulphovinate and 42.8 parts of quinine sulphate, the former in 200, the latter in 600, parts of alcohol, mixing the solutions, filtering from the precipitated sodium sulphate, and evaporating. It crystallizes with difficulty in prisms, dissolves in 3 parts of water at 15° C. (59° F.), in a less amount of alcohol, and dissolves likewise in acetic ether and glycerin, but not in strong ether or benzene. It contains 71.99 per cent. of quinine.

QUININÆ BISULPHAS, *U. S.*—Quinine Bisulphate.

Sulfate de quinine neutre, Fr. Cod.; *Chininum bisulfuricum, Quininæ sulphas acidus.*—*Acid quinine sulphate,* E.; *Sulfate acide de quinine,* Fr.; *Saures Chininsulfat, Chininbisulfat,* G.

Formula, $C_{20}H_{24}N_2O_2H_2SO_4 + 7H_2O$. Molecular weight, 544.33.

Quinine bisulphate should be kept in well-stoppered bottles in a dark place.—U. S.

Preparation.—Mix 100 grains of ordinary quinine sulphate with about 500 grains (9 fluidrachms) of warm distilled water; add to the mixture 115 grains of official diluted sulphuric acid; filter if necessary, and set aside in a moderately warm place to crystallize; dry the crystals over sulphuric acid at a temperature of 10° or 15° C. (50° or 59° F.), and preserve them in a well-stoppered bottle in a cool and dark place. The yield is 125 grains.

A solution of the salt may be prepared extemporaneously by dissolving 8 grains of

quinine sulphate in water with the aid of 9 minims (or 9½ grains) of diluted sulphuric acid; the solution will contain 10 grains of acid quinine sulphate.

Properties.—Quininæ bisulphate occurs as colorless, transparent or whitish, orthorhombic crystals or small needles, odorless, and having a very bitter taste. It effloresces on exposure to the air, and turns yellow on exposure to the light. Soluble in 8.5 parts of water, 18 parts of alcohol, 1770 parts of ether, 920 parts of chloroform, and in 18 parts of glycerin at 25° C. (77° F.); soluble in 0.68 part of water at 80° C. (176° F.), and in 0.5 part of alcohol at 60° C. (140° F.). When heated, the salt softens at 60° C. (140° F.), becomes semi-fluid at 70° C. (158° F.), and melts at about 160° C. (320° F.), with decomposition. It loses all of its water of crystallization at 100° C. (212° F.). On ignition, the salt is slowly consumed, leaving no residue. Its aqueous solution has a strongly acid reaction and shows a blue efflorescence.

Barium chloride test-solution produces a white precipitate, insoluble in hydrochloric acid. If 1 Gm. of the salt be dried at 100° C. (212° F.) until it ceases to lose weight, the remainder, cooled in a desiccator, should weigh not less than 0.77 Gm. (corresponding to 7 molecules or 23 per cent. of water of crystallization). If to 1 Cc. of an aqueous solution of quinine bisulphate (1 in 100) should be added 2 Cc. of bromine test-solution, and then 1 Cc. of ammonia-water, the liquid should acquire an emerald-green color (thalleioquin).—U. S. The salt fuses in a glass tube at 80° C. (176° F.), but heated in the air it melts near 135° C. (275° F.), and is converted into acid quinicine sulphate, which is easily soluble in alcohol and water, its solution in dilute sulphuric acid being yellow without blue fluorescence, and crystallizes in long yellow prisms. Quinine bisulphate contains 59.12 per cent. of quinine.

The pharmacopœial salt should not be confounded with the true *quinine bisulphate*, $C_{20}H_{24}N_2O_2(H_2SO_4)_2 + 7H_2O$, which is obtained from 100 grains of quinine sulphate and 350 grains of diluted sulphuric acid, the solution being crystallized over sulphuric acid. It contains 19.5 per cent. of water, readily acquires a brown-red color on exposure to light, is easily soluble in water with a strong blue fluorescence, and separates from boiling alcohol on cooling as a gelatinous mass, which on drying forms minute prisms.

Tests.—Sulphuric acid should produce not more than a faintly yellow tint (limit of carbonizable organic impurities). Dissolve 2 Gm. of quinine bisulphate, which has been dried at 50° C. (122° F.) for 2 hours, in 20 Cc. of distilled water, carefully neutralize with diluted sodium hydroxide test-solution, and evaporate the solution to dryness on a water-bath. Complete the test by following the directions given on page 1296, under QUININÆ SULPHAS (Test for Other Cinchona Alkaloids, Section II.).—U. S.

Action and Uses.—On account of its greater solubility this salt is to be preferred to the sulphate. It contains 15 per cent. less quinine than the sulphate, and the dose is correspondingly larger. Dose, as a tonic, 1 to 3 grains (0.06–0.20 Gm.); as an antiperiodic, 5 to 30 grains (0.30–2 Gm.).

QUININÆ HYDROBROMIDUM, *U. S.*—Quinine Hydrobromide.

Bromhydrate de quinine basique, Fr. Cod.; *Chininum hydrobromicum.—Bromhydrate de quinine*, Fr.; *Chininhydrobromid, Bromwasserstoffsaures Chinin*, G.

Formula, $C_{20}H_{24}N_2O_2HBr + H_2O$. Molecular weight, 420.06.

The hydrobromide of the alkaloid quinine. It should be kept in well-stoppered, amber-colored vials.—U. S.

Preparation.—This salt is prepared by double decomposition of quinine sulphate with barium bromide. A mixture of 100 grains of quinine sulphate and 1400 grains (3 fluidounces) of water is heated to boiling, and gradually mixed with a solution of 34 grains of barium bromide in 225 grains (½ fluidounce) of water; the precipitate is allowed to settle, and the clear hot liquid is tested for barium salt with a cold solution of quinine sulphate prepared without the aid of additional acid, and if free from barium is filtered and evaporated to crystallize. The yield is about 100 grains. Owing to the insolubility of barium chloride and the ready solubility of barium bromide in absolute alcohol, Boille (1874) recommends dissolving both the barium and the quinine salts in strong alcohol; the solutions are then mixed, taking care that the quinine sulphate is in slight excess; after filtering, water is added, the alcohol distilled off, the liquid cooled, filtered from any quinine sulphate which may crystallize out, and evaporated to crystallize. If the salt be not quite white, it should be recrystallized from water.

The salt may also be prepared by dissolving quinine in warm diluted hydrobromic acid until the acid reaction has completely disappeared. Or, according to Hager, 100 parts of quinine sulphate and 27.5 parts of potassium bromide are well triturated with 100 parts of water; the mixture is moderately heated, mixed with 400 parts of alcohol, the whole digested for an hour, filtered while warm from the precipitated potassium sulphate, and crystallized. Leger's process (1880) is similar to this.

Properties.—Quinine hydrobromide occurs as white, light, silky needles; odorless, and having a very bitter taste. The salt effloresces on exposure to the air. Soluble in 40 parts of water, 0.67 part of alcohol, 16 parts of ether, 8 parts of glycerin, and very soluble in chloroform at 25° C. (77° F.); soluble in 3 parts of water at 80° C. (176° F.). When heated to 100° C. (212° F.) the salt loses its water of crystallization. At 152° C. (305.6° F.) it begins to fuse, forming a syrupy liquid at 200° C. (392° F.). On ignition it is slowly consumed, leaving no residue. Its solutions are neutral or slightly alkaline to litmus-paper, and when acidulated with diluted sulphuric acid show a vivid blue fluorescence. Ammonia-water added to an aqueous solution of the salt produces a white precipitate, which is soluble in a large excess of the reagent. On precipitating a saturated aqueous solution of the salt with sodium hydroxide test-solution, filtering, supersaturating the filtrate with acetic acid, adding chloroform and a little chlorine-water, and shaking, the chloroform will separate with a yellow color. If 1 Gm. of the salt be dried at 100° C. (212° F.) until it ceases to lose weight, the residue should weigh not less than 0.957 Gm. (corresponding to 1 molecule, or 4.25 per cent. of water of crystallization). If to 1 Cc. of a solution of quinine hydrobromide (1 in 100) 2 Cc. of bromine test-solution be added, and then 1 Cc. of ammonia-water, an emerald-green color should be produced (thalleioquin).—U. S.

Tests.—Quinine hydrobromide should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of readily carbonizable organic impurities) nor produce a red color with nitric acid (difference from morphine). Aqueous solutions of the salt should not be rendered more than faintly turbid by barium chloride test-solution (limit of sulphate). If to 5 Cc. of a saturated aqueous solution of potassium ferricyanide 25 Cc. of water, 15 drops of ferric chloride test-solution, and 5 Cc. of diluted hydrochloric acid be added, a clear brown solution should result. On adding to this 0.1 Gm. of quinine hydrobromide, shaking well, and allowing it to stand for 5 minutes, no blue color should be developed (difference from morphine). Dissolve 3 Gm. of quinine hydrobromide, which has been dried at 50° C. (122° F.) for 2 hours, in 30 Cc. of hot distilled water in an evaporating dish, and add 1.5 Gm. of crystallized sodium sulphate gradually, with constant stirring, and evaporate the liquid on a water-bath to dryness. Complete the test by following the directions given on page 1296, under QUININÆ SULPHAS (Test for Other Cinchona Alkaloids, Section II.), using 30 Cc. of distilled water for maceration instead of 20 Cc. as there directed.—U. S.

Action and Uses.—This salt possesses no advantages over the bisulphate or hydrochloride. Unless given in very large dose the bromide radical exerts no influence. It is less soluble than the bisulphate, and consequently not so well suited for hypodermatic administration. The dose is the same as that of QUININE SULPHATE.

Allied Salt. QUININÆ HYDROBROMIDUM ACIDUM. *Acid quinine hydrobromide.* $C_{20}H_{24}N_2O_2(HBr)_2 + 3H_2O$.—Quinine sulphate is dissolved in water with the aid of sufficient dilute sulphuric acid, completely precipitated with a solution of barium bromide, avoiding an excess of the latter, the solution filtered from the barium sulphate, and evaporated to crystallize. This salt is soluble in 6 parts of water and is freely soluble in alcohol. It contains 60.02 per cent. quinine and 29.97 per cent. hydrobromic acid.

QUININÆ HYDROCHLORIDUM, *U. S., Br.*—Quinine Hydrochloride.

Chininum hydrochloricum, P. G.; *Chlorhydrate de quinine basique*, Fr. Cod.; *Muriate of quinine*, E.; *Chlorhydrate de quinine*, Fr.; *Chininhydrochlorid, Salzsaures Chinin*, G.

Formula, $C_{20}H_{24}N_2O_2HCl + 2H_2O$. Molecular weight, 393.76.

The hydrochloride of the alkaloid quinine. It should be kept in well-stoppered, amber-colored vials.—U. S.

Preparation.—The salt is perhaps best obtained by dissolving quinine in warm diluted hydrochloric acid until the solution is neutral, and crystallizing. The French Pharmacopœia directs that it be prepared by mutual decomposition as follows: A solu-

tion of 28 Gm. of barium chloride in 200 Gm. of distilled water is added slowly to a boiling solution of 100 Gm. of quinine sulphate in 800 Gm. of distilled water. The precipitated barium sulphate is removed by filtration, washed with boiling water, and the filtrate evaporated and allowed to crystallize in the cold.

Properties.—Quinine hydrochloride occurs as white, silky, glistening needles; odorless, and having a very bitter taste. The salt effloresces when exposed to warm air. Soluble in 18 parts of water, 0.6 part of alcohol, 240 parts of ether, 0.8 part of chloroform, and in 8 parts of glycerin at 25° C. (77° F.); soluble in 0.4 part of water at 80° C. (176° F.). When heated to 120° C. (248° F.) the salt loses its water of crystallization. At about 156° C. (312° F.) it begins to melt, but is not fully melted until the temperature reaches 190° C. (374° F.). On ignition, it is slowly consumed, leaving no residue. Its aqueous solution is neutral or faintly alkaline to red litmus-paper, and is not fluorescent except when greatly diluted, or when diluted sulphuric acid is added to it. Silver nitrate test-solution produces in aqueous solutions of the salt a white precipitate, insoluble in nitric acid. If 1 Gm. of the salt be dried at 100° C. (212° F.) until it ceases to lose weight, the residue should weigh 0.91 Gm. (corresponding to 2 molecules or 9.1 per cent. of water of crystallization). If to 1 Cc. of a solution of quinine hydrochloride (1 in 100) 2 Cc. of bromine test-solution be added, and then 1 Cc. of ammonia-water, an emerald-green color should be produced (thalleioquin).—U. S.

The British and German pharmacopœias give the solubility of quinine hydrochloride as 1 part in 35 parts of cold water or 3 parts of cold alcohol, whereas the French Codex states that 25 parts of water at 15° C. (59° F.) will dissolve the salt. On being exposed to light quinine hydrochloride gradually acquires a yellowish color, and its solution likewise becomes yellowish or brownish on keeping. It contains 81.73 per cent. of quinine.

Tests.—Sulphuric acid should produce no color (absence of organic impurities). Aqueous solutions of the salt should not be rendered more than faintly turbid by barium chloride test-solution (limit of sulphate). If to 5 Cc. of a saturated solution of potassium ferricyanide 25 Cc. of water, 15 drops of ferric chloride test-solution, and 5 Cc. of diluted hydrochloric acid be added, a clear brown solution should result. On adding to this 0.1 Gm. of quinine hydrochloride, shaking well, and allowing it to stand for 5 minutes, no blue color should be developed (difference from morphine). Dissolve 3 Gm. of quinine hydrochloride, which has been dried at 50° C. (122° F.) for 2 hours, in 30 Cc. of hot distilled water in an evaporating dish, and add 1.5 Gm. of crystallized sodium sulphate gradually with constant stirring, and evaporate the liquid on a water-bath to dryness. Complete the test by following the directions given on page 1296, under QUININÆ SULPHAS (Test for Other Cinchona Alkaloids, Section II.), using 30 Cc. of distilled water for maceration instead of 20 Cc., as there directed.—U. S.

Action and Uses.—Quinine hydrochloride may be used interchangeably with the other quinine salts and in the same doses. It is claimed for it that when administered by hypodermatic injection it is less liable to produce abscesses than the other salts.

QUININÆ HYDROCHLORIDUM ACIDUM, *Br.*—Acid Quinine Hydrochloride.

Chlorhydrate de quinine neutre, Fr.; *Saures Chininhydrochlorid, Saures Chlorwasserstoffsaures Chinin*, G.

Formula, $C_{20}H_{24}N_2O_2.2HCl + 3H_2O$. Molecular weight, 447.82.

The acid hydrochloride of an alkaloid obtained from the bark of various species of cinchona and remijia.—Br.

This salt was introduced into the British Pharmacopœia of 1898 on account of its greater solubility than the ordinary hydrochloride.

Preparation.—Acid quinine hydrochloride is conveniently prepared by adding a solution of 4.45 parts of crystallized barium chloride, dissolved in 50 parts of distilled water, to a solution of 10 parts of quinine bisulphate, dissolved in 50 parts of water. The solutions are thoroughly mixed and, after standing some time, filtered. The filtrate is evaporated at a temperature not exceeding 60° C. (140° F.) and crystallized. The salt may also be prepared from the official hydrochloride by dissolving 10 parts of quinine hydrochloride in 20 parts of distilled water, adding 3.7 parts of 25 per cent. hydrochloric acid, and crystallizing the salt.

Properties.—Acid quinine hydrochloride occurs as a white crystalline powder, soluble in less than its own weight of water, and yielding a somewhat acid liquid. It affords the reactions characteristic of hydrochlorides. It should yield only the slightest characteristic reactions with the tests for sulphates. Each gramme, when dissolved in 20 Cc. of water, should require for its complete neutralization not more than 2.5 Cc. of volumetric test-solution of soda. When converted into quinine sulphate, by dissolving it together with an equal weight of sodium sulphate in 10 times its weight of hot water, exactly neutralizing this liquid with solution of ammonia, and setting it aside at 15.5° C. (60° F.) to cool, it should respond to the characters and tests which are mentioned under QUININÆ SULPHAS. Dried at a temperature of 100° C. (212° F.), it loses not more than 12 per cent. of water.—Br. The salt contains 71.86 per cent. of quinine, 16.16 per cent. of hydrochloric acid, and 11.98 per cent. of water of crystallization.

Action and Uses.—This is a very soluble salt of quinine and is usually employed hypodermatically in the dose of from 1 to 5 grains (0.06–0.30 Gm.).

QUININÆ SALICYLAS, *U. S.*—Quinine Salicylate.

Salicylate de quinine basique, Fr. Cod.—*Salicylate de quinine*, Fr.; *Chininsalicylat, Salicylsaures Chinin*, G.

Formula, $2C_{20}H_{24}N_2O_2.C_7H_6O_3 + H_2O$ or $2C_6H_4(OH)COOH.C_{20}H_{24}N_2O_2 + H_2O$. Molecular weight, 935.54.

The salicylate of the alkaloid quinine. It should be kept in amber-colored, well-stoppered vials.—U. S.

Preparation.—Quinine salicylate is prepared by double decomposition of a quinine salt and a soluble salicylate. Dissolve 10 parts of quinine sulphate in 75 parts of water heated to boiling, and precipitate the hot solution with 3.89 parts of sodium salicylate dissolved in 30 parts of water. Allow the mixture to cool, and wash it with cold distilled water until free from sulphate.

Properties.—Quinine salicylate occurs as colorless needles, permanent in the air, but on keeping readily assuming a pinkish color. Soluble in 77 parts of water, 11 parts of alcohol, 110 parts of ether, 37 parts of chloroform, and in 16 parts of glycerin at 25° C. (77° F.); soluble in 35 parts of water at 80° C. (176° F.) and in 11 parts of alcohol at 60° C. (140° F.). When heated, it begins to melt at 183° C. (361.4° F.), with decomposition, and at 187° C. (368.6° F.) is entirely melted to a red liquid. When ignited it is slowly consumed, without leaving a residue. Its aqueous solution is alkaline to red litmus-paper and has a bitter taste. When heated with diluted sulphuric acid its aqueous solution develops a blue fluorescence. Its aqueous solution, when treated with a drop of ferric chloride test-solution, should give a violet color. Sulphuric acid containing about one-fifth of its volume of solution of formaldehyde gives a pink color. If 10 Cc. of a dilute aqueous solution of quinine salicylate be treated with 3 Cc. of bromine test-solution, and then an excess of ammonia-water, an emerald-green color should be produced (thalleioquin).—U. S. Quinine salicylate contains 68.8 per cent. of quinine, 29.92 per cent. of salicylic acid, and 1.91 per cent. of water. It is crystallizable from alcohol in anhydrous prisms.

Tests.—When heated at 100° C. (212° F.), to constant weight, it should lose not more than 2 per cent. in weight (absence of excessive moisture). Mix 2 Gm. of quinine salicylate with 10 Cc. of distilled water in a separator, add a slight excess of ammonia-water, and shake the liquid with three successive portions of 25, 20, and 10 Cc. of ether, collect the ether solution in a porcelain dish, and evaporate it to dryness on a water-bath, dissolve the residue in alcohol, add just sufficient sulphuric acid to render the liquid neutral, and again evaporate to dryness. Complete the test by following the directions given on page 1296, under QUININÆ SULPHAS (Test for Other Cinchona Alkaloids, Section II.).—U. S.

Action and Uses.—Aside from the employment of this salt as an antiperiodic it is used to relieve the pains of chronic rheumatism and gout. The dose as an antirheumatic is from 2 to 10 grains (0.12-0.60 Gm.).

QUININÆ SULPHAS, *U. S., Br.*—Quinine Sulphate.

Chininum sulfuricum, P. G.; *Sulfate de quinine basique, Sulfate de quinine officinal*, Fr. Cod.—*Quiniæ sulphas, Sulphate of quinia*, E.; *Sulfate de quinine*, Fr.; *Chininsulfat, Schwefelsaures Chinin*, G.

Formula, $(C_{20}H_{24}N_2O_2)_2H_2SO_4 + 7H_2O$. Molecular weight, 866.15.

The sulphate of the alkaloid quinine. It should be kept in well-stoppered bottles, preferably of an amber color, and in a dark place.—U. S. The sulphate of an alkaloid obtained from the bark of various species of cinchona and remijia.—Br.

Preparation.—Formerly the alkaloids of cinchona bark, which are in combination with quinic, quinovic, and cinchotannic acids, were extracted by treating the ground bark with diluted hydrochloric or sulphuric acid, and then precipitated from the resulting solutions by means of alkalies. Commercially quinine is now commonly obtained by mixing the finely ground bark with milk of lime, whereby the alkaloids are liberated in a condition comparatively free from coloring-matter and other undesirable by-products. The resulting mixture is then treated with hydrocarbon oils from petroleum, which have the power to dissolve the free alkaloids. The latter solution is removed and thoroughly agitated with diluted sulphuric acid, which takes up all the alkaloids in the form of sulphates. By neutralizing the acid aqueous solution with sodium carbonate and crystallizing, an impure quinine sulphate is obtained containing much cinchonidine and hydroquinine, from which it is freed, after solution in hot water and treating with animal charcoal, by recrystallization and conversion into bisulphate and again crystallizing. The bisulphate is dissolved and carefully neutralized with sodium carbonate, when upon cooling of the solution quinine sulphate crystallizes out. Various modifications of the processes above outlined are no doubt used by manufacturers, and the exact methods employed for obtaining quinine sulphate of the purity demanded by the pharmacopœias are carefully guarded as secrets.

The World's Production of Quinine Sulphate.—According to a report by the director of plantations of cinchona for British India, the Madras Government in 1902 manufactured 15,711 pounds of quinine and Bengal 11,297 pounds, a total production for India of 27,008 pounds. The island of Java produced and exported 43,750 pounds.

The different countries producing the bark exported in 1902 the following quantities: Java, 14,726,000 pounds; India, 1,020,000 pounds; Ceylon, 407,000 pounds; South America, 775,000 pounds; Africa, 178,872 pounds; a total of 17,106,872 pounds.

There are 20 establishments in the world manufacturing quinine, distributed as follows: 5 in France, 3 in England, 2 in Germany, 2 in Italy, 1 in Holland, 4 in America, 1 in Java, 1 in Bengal, and 1 in the Madras Presidency.—*R. M. Bartleman, Consul, Cadiz, Spain, June 13, 1904.*

Properties.—Quinine sulphate occurs as white, silky, flexible, glistening crystals, or hard, prismatic, monoclinic needles, making a very light and easily compressible mass, odorless, and having a persistent, very bitter taste. It effloresces rapidly when it is exposed to dry air and then becomes lustreless; when exposed to light it acquires a brownish tint. Quinine sulphate sometimes crystallizes with 8 molecules of water of crystallization (16.18 per cent.). Soluble in 720 parts of water, 86 parts of alcohol, 400 parts of chloroform, and in 36 parts of glycerin at 25° C. (77° F.); very difficultly soluble in ether; soluble in 45 parts of water at 80° C. (176° F.), and in 9 parts of alcohol at 60° C. (140° F.). Diluted acids increase its solubility in water, and it is easily soluble in a mixture of chloroform 2 parts and absolute alcohol 1 part. Quinine sulphate which has been dried over sulphuric acid melts at 205° C. (401° F.). When heated to 60° C. (140° F.) or when exposed to dry air it loses all but 2 molecules of its water of crystallization, and upon heating it to 115° C. (239° F.) the remainder is expelled. Upon ignition the salt is slowly consumed, without leaving a residue. Its aqueous solution is neutral to litmus-paper, and when acidulated with diluted sulphuric acid develops a vivid blue fluorescence. Barium chloride test-solution produces a white precipitate, insoluble in hydrochloric acid. On treating 10 Cc. of an aqueous solution (about 1 in 1300) of the salt with 5 drops of bromine test-solution, then with an excess of ammonia water, the liquid should acquire an emerald-green color (thalleioquin). With proper adjustment of the reagents more diluted solutions will give a paler

tint, while more concentrated ones will acquire a deeper color or throw down a green precipitate.

Tests.—1 Gm. of the salt should dissolve completely when heated to 50° C. (122° F.) in 7 Cc. of a mixture of 2 volumes of chloroform and 1 volume of absolute alcohol, and should remain clear on cooling (absence of ammonium sulphate and inorganic salts). Sulphuric acid should impart to the salt not more than a faintly yellowish tint (limit of readily carbonizable organic impurities). Nitric acid should not produce a red color (difference from morphine). If 1 Gm. of the salt be dried at a temperature of 115° C. (239° F.) until it ceases to lose weight, the residue should weigh not less than 0.838 Gm. (indicating not more than 8 molecules, or 16.18 per cent of water).

Test for Other Cinchona Alkaloids.—I. Dry 2 Gm. of quinine sulphate in a porcelain dish on a water-bath for 2 hours at 50° C. (122° F.). II. Transfer the residue (which should be strictly neutral to test-paper) to a dry test-tube, add 20 Cc. of distilled water, and place the test-tube in a water-bath; heat it for ½ hour at 65° C. (149° F.), and then allow it to cool, keeping the temperature at 15° C. (59° F.) for 2 hours, shaking the test-tube occasionally. Filter the liquid, transfer 5 Cc. of the filtrate, having the temperature of 15° C. (59° F.), to a dry test-tube, and carefully add ammonia-water (which must be of official strength and have the temperature of exactly 15° C.—59° F.) until the precipitate which forms has just redissolved; not more than 6 Cc. of ammonia-water should be required to produce a clear solution. If the temperature at the end of the digestion has risen to 16° C. (60.8° F.), then 6.5 Cc. of ammonia-water should be required; if to 17° C. (62.6 F.), 7 Cc. of ammonia-water should be used. (In each case a clear solution indicates the absence of excessive amounts of other cinchona alkaloids).—U. S. This test is known as Kerner's test, and is likewise given in the German Pharmacopœia, where, however, the demand is somewhat more rigid, as not more than 4 Cc. of ammonia-water are allowed to produce a clear solution at 15° C. (59° F.). Schaefer's oxalate test is more delicate than the preceding, and will detect as little as 2 per cent. of foreign alkaloids (hydroquinine and cinchonidine). 1 Gm. of quinine sulphate is placed in a tared flask and dissolved in 35 Cc. of boiling distilled water. 0.3 Gm. of crystallized neutral potassium oxalate dissolved in 5 Cc. of water are then added, and distilled water added thereto until the contents of the flask weigh 41.3 Gm. The flask is then placed in a water-bath at 20° C. (68° F.) for ½ hour, and shaken occasionally, after which the solution is filtered through glass wool. To 10 Cc. of the filtrate add a drop of solution of sodium hydroxide. No turbidity should result in the course of a few minutes.

The British Pharmacopœia gives the following tests for the absence of other cinchona alkaloids:

Test for Cinchonidine and Cinchonine.—"Dissolve 4 Gm. of the quinine sulphate in 120 Cc. of boiling water. Cool the solution slowly to 50° C. (122° F.), with frequent stirring. Separate, by filtration, the purified quinine sulphate which has crystallized out. Concentrate the filtrate by evaporation until it is reduced to 10 Cc. or less; transfer to a small stoppered flask, and, when cold, shake with 10 Cc. of ether and half that amount of solution of ammonia. Set aside in a cool place for not less than 24 hours. Collect the crystals, which consist of cinchonidine and cinchonine, with quinine, on a tared filter, wash with a little ether, dry at 100° C. (212° F.), and weigh. These should not amount to more than 0.120 Gm."—Br.

Test for Quinidine.—"Dissolve 1 Gm. of the quinine sulphate in 30 Cc. of boiling water; cool, and filter. To the solution add solution of potassium iodide and a little alcohol (90 per cent.) to prevent the precipitation of amorphous hydriodides. Collect any separated quinidine hydriodide, wash with a little water, dry, and weigh. The weight represents about an equal weight of crystallized quinidine sulphate. None or only the slightest traces should be obtained."—Br.

Test for Cupreine.—"Shake the recrystallized quinine sulphate obtained in testing the original quinine sulphate for cinchonidine and cinchonine with 25 Cc. of ether and 6 Cc. of solution of ammonia, and to this ethereal solution, separated, add the ethereal liquid and washings also obtained in testing the original sulphate for the two alkaloids just mentioned. Shake this ethereal liquid with 6 Cc. of a 10 per cent. solution of sodium hydroxide, adding water if any solid matter should separate. Remove the ethereal solution. Wash the aqueous solution with more ether and remove the ethereal washings. Add diluted sulphuric acid to the aqueous liquid heated to boiling until exactly natural.

When cold collect any crystallized sulphate of cupreine on a tared filter; dry, and weigh. None or only the slightest traces should be obtained."—Br.

Test for Cinchonine and Amorphous Alkaloids.—"Dissolve 1 Gm. of the quinine sulphate in 30 Cc. of boiling water, add 1 Gm. of sodium potassium tartrate. Allow to cool with frequent stirring; filter. The solution when evaporated to small bulk should give little or no precipitate with solution of ammonia."—Br.

Action and Uses.—For the action and uses of this salt, see the article on QUININE.

QUININÆ TANNAS.—Quinine Tannate.

Tannate de quinine, Fr. Cod.; *Chininum tannicum*, P. G.—*Chinintannat, Gerbsaures Chinin*, G.

Formula, $C_{20}H_{24}N_2O_2.3C_{14}H_{10}O_9 + 8H_2O$ or $C_{20}H_{24}N_2O_2.2C_{14}H_{10}O_9 + 4H_2O$. Molecular weight, 1423.84 or 1033.66.

Preparation.—Quinine tannate may be prepared by dissolving 9 Gm. of quinine sulphate in 225 Gm. of water with the aid of 10 Gm. of 16 per cent. sulphuric acid and adding to the solution after filtration, with constant stirring, a solution of 21 Gm. of tannic acid and 3.5 Gm. of sodium bicarbonate in 250 Gm. of water. The precipitate is collected on a filter and washed with small quantities of water until the filtrate after acidulation with nitric acid is no longer rendered turbid by addition of barium chloride solution. It is finally dried at a temperature not exceeding 30° to 35° C. (86°–95° F.) and reduced to powder.

This is the official process of the Swiss Pharmacopœia. De Vrij (1898) proposed to make quinine tannate by triturating 1 part of quinine alkaloid, 4 parts of tannic acid, and 10 parts of water together, and evaporating the mixture to dryness at a temperature not exceeding 60° C. (140° F.). The French Pharmacopœia directs that quinine alkaloid be dissolved in water with the aid of acetic acid to very slight acidity. To this solution a solution of tannic acid is added in sufficient quantity to redissolve the resulting precipitate, and finally the liquid is neutralized with sodium bicarbonate. The final precipitate is filtered off and powdered, and then washed with distilled water, and again dried and powdered.

Properties and Tests.—Quinine tannate is a yellowish-white, amorphous, odorless powder, having a faintly bitter and barely astringent taste. It is soluble in about 800 parts of cold or 50 parts of boiling water; in 60 parts of cold or 6 parts of boiling alcohol; also in 100 parts of cold or 10 parts of hot glycerin. Solutions of quinine tannate are colored blue black by solutions of ferric salts. If 1 Gm. of quinine tannate be mixed with 4 Cc. of water, and the mixture made strongly alkaline with solution of sodium hydroxide and extracted with three successive portions of 7 Cc. of ether, the combined ether extracts, upon evaporation of the ether and drying the residue at 100° C. (212° F.), should weigh not less than 0.3 Gm. and answer to the requirements for the purity of the alkaloid quinine (P. G.). While the German Pharmacopœia demands that the salt shall contain 30 to 32 per cent. of anhydrous quinine, the Swiss Pharmacopœia demands from 30 to 35 per cent. and the French Codex from 20 to 21 per cent.

Action and Uses.—As quinine tannate is quite insoluble it cannot be successfully used when large doses of quinine are indicated, especially in malaria.

Because of its sparing solubility, and consequent but slightly bitter taste, it is administered to children and others who cannot swallow pills or capsules. In these cases it is given in powder, suspended in syrups or mucilages, or combined with powdered chocolate in lozenges called quinine chocolates. The dose is from 2 to 10 grains (0.12–0.60 Gm.).

QUININÆ VALERAS.—Quinine Valerate.

Valérianate de quinine, Fr. Cod.; *Quininæ valerianas*, U. S., 1890; *Chininum valerianicum*; *Quinine valerianate*, E.; *Valérate de quinine*, Fr.; *Chininvalerianat, Baldriansaures Chinin*, G.

Formula, $C_{20}H_{24}N_2O_2.C_5H_{10}O_2$. Molecular weight, 423.13.

Preparation.—The French Pharmacopœia directs that hydrated quinine alkaloid be dissolved in the least possible quantity of alcohol, and valerianic acid then added in small quantities until the solution shows a feeble reaction. The mixture is poured into

twice its volume of water and then allowed to evaporate at a temperature not exceeding 50° C. (122° F.), so as to cause crystals to form.

Properties.—Quinine valerate crystallizes in colorless, pearly, rhomboidal tables or in white triclinic needles having a weak odor of valerianic acid, a bitter, somewhat valerian-like taste, and a neutral reaction. The salt dissolves in 10 parts of cold and 40 parts of boiling water, in 6 parts of cold and 1 part of boiling 80 per cent. alcohol, and is easily soluble in ether (Fr. Cod.). On adding dilute sulphuric acid to the aqueous solution it becomes fluorescent, and the odor of valerianic acid is rendered more apparent. Ammonia gives a white precipitate soluble in an excess of the precipitant and in ether, and with chlorine-water and ammonia an emerald-green color is produced. The salt is permanent in the air; it melts at 90° C. (194° F.), forming a colorless liquid. At 100° C. (212° F.) it loses its water of crystallization and also begins to lose valerianic acid. When strongly heated on platinum foil it is decomposed, and burns slowly without leaving any residue. It contains 76.06 per cent. of quinine.

Tests.—On treating 10 Cc. of an aqueous solution (about 1 in 1300) of the salt with 5 drops of bromine test-solution, and then with an excess of ammonia-water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will show a paler tint, while more concentrated ones will acquire a deeper color or throw down a green precipitate.

The aqueous solution should remain clear or become merely turbid (produce not more than a slight precipitate on the addition of test-solution of barium chloride). The precipitate occasioned by ammonia-water should be readily dissolved on adding an excess of the latter (absence of cinchonine). The salt is tested for fixed impurities by incineration, for ammonia salt by lime or potassa, and for organic impurities, morphine, and other alkaloids, by strong sulphuric and nitric acid, as described under QUININÆ SULPHAS.

Action and Uses.—There seems to be no foundation for the belief that quinine valerate is superior to other quinine salts in migraine, neuralgia, or debility of nervous origin. The dose is from 1 to 5 grains (0.06–0.30 Gm.).

QUINOLINA.—Quinoline.

Chinolina.—Quinoline, Fr.; *Chinolin*, G.

Formula, C_9H_7N. Molecular weight, 128.12.

An artificial volatile alkaloid obtained by the destructive distillation of quinine and cinchonine, or strychnine and brucine, with potassium hydroxide, or synthetically by the action of sulphuric acid upon a mixture of glycerin, nitrobenzene, and aniline.

Preparation.—Runge (1834) separated a basic body, *leucoline*, from coal-tar, and Gerhardt (1842) obtained a pure base, *chinoleine*, by distilling quinine with potassium hydroxide. Both alkaloids were later (Hoogewerff and v. Dorp, 1883) shown to be identical with purified *quinoline*, obtained by Williams (1855). It is now prepared mostly by the method of Skraup: 24 parts of nitrobenzene, 38 parts of aniline, 120 parts of glycerin, and 100 parts of concentrated sulphuric acid are mixed, and only gently heated for some time to prevent a too violent reaction. It is then heated under a reflux condenser for several hours, and after completion of the reaction, the mixture is diluted with water and the nitrobenzene removed by distillation. Lime or sodium hydroxide is then added in excess, and the quinoline distilled in a current of steam. The distillate is purified by fractionation and the quinoline precipitated as an acid sulphate from its alcoholic solution by the addition of sulphuric acid. In this method glycerin is converted into acrolein by the sulphuric acid, and this combines with the aniline under the oxidizing influence of the nitrobenzene, forming quinoline. About 60 per cent. of the theoretical yield is obtained by this method.

Prepared from the cinchona alkaloids, quinoline is apt to contain some of the higher homologues—*lepidine*, $C_9H_6(CH_3)N$, and *despoline*, $C_{11}H_{11}N$, while that obtained from coal-tar may contain a large percentage of *quinaldine*, $C_9H_6(CH_3)N$, boiling at 239° C. (462.2° F.), and the isomer *iridoline*, boiling at 252° to 257° C. (485.6°–494.6° F.). Quinoline is a tertiary amine, and may be looked upon as naphthalene, $C_{10}H_8$, in which an atom of N has displaced one of the group CH. Two isomeric forms are possible.

Properties.—Pure quinoline is a colorless or faintly yellow, mobile, highly refractive liquid, with a peculiar aromatic odor, resembling that of oil of bitter almond, and a

pungent peppermint-like after-taste. Its specific gravity at 15° C. (59° F.) is 1.084 (1.093–1.096, Hager) and its boiling-point 237° C. (458.6° F.). It slowly volatilizes at ordinary temperatures, and, exposed to a freezing mixture of solid carbon dioxide and ether, congeals to a crystalline mass. It is difficultly soluble in hot water, but miscible with ethyl, methyl, and amyl alcohol, ether, benzene, chloroform, carbon bisulphide, fixed and volatile oils, and is a solvent of camphor and some resins. Although quinoline is quite insoluble in water, it is hygroscopic, and if exposed to a damp atmosphere forms a hydrate, $C_9H_7N+1\frac{1}{2}H_2O$, which becomes turbid at 40° C. (104° F.). Exposed to light and air it rapidly turns brown, but may be decolorized by shaking with fixed alkali hydroxide and slow rectification. It possesses strong basic properties and forms odorless crystallizable salts, which develop the quinoline odor on treatment with fixed alkali hydroxide. It is readily converted into quinoline sulphonic acid by the action of fuming sulphuric acid, and on fusion with potassium hydroxide yields oxyquinoline, C_9H_6NOH. (See KAIRIN.) With zinc and bismuth it forms crystallizable double salts.

Quinoline is precipitated from its aqueous solutions, not too dilute, by fixed alkali hydroxides, and by most of the reagents for alkaloids. Iodine in potassium iodide produces a reddish-brown precipitate (1 to 25,000 parts); phosphomolybdate, a yellowish-white precipitate (1 to 25,000 parts); potassium mercuric iodide, a yellowish-white *amorphous* precipitate (1 to 3500 parts), which, on the addition of hydrochloric acid, is converted into *amber-colored crystals;* picric acid, a yellow precipitate; potassium ferrocyanide, a deep-red solution. It dissolves without color in nitric and sulphuric acid. Heated with sodium, *diquinolyline*, $C_9H_6N.C_9H_6N$, is formed, and when polymerized, yellow needles of *diquinoline*, $(C_9H_7N)_2$, are obtained. By acting on quinoline with amyl iodide, and afterward with soda *cyanine*, a basic coloring-matter, crystallizing in golden-green plates having a metallic lustre and dyeing silk blue, is produced.

Tests.—Quinoline should dissolve clear in dilute hydrochloric acid, or, when shaken with about 50 parts of water and filtered, the filtrate should not give a violet color with chlorinated lime (aniline). It is identified by its odor, and the reactions with potassium ferrocyanide and potassium mercuric iodide.

Action and Uses.—Quinoline is of interest as being probably the first of the coal-tar products to be used as an antipyretic as a substitute for quinine. It was soon discovered, however, that while it produced a marked reduction in temperature in malaria, it exercised no influence upon the cause or duration of the disease. Profound collapse following its administration was not infrequent and its use was soon abandoned. This depression is less marked in some of its derivatives, notably analgen and thermofugin, but even they are more depressing than antipyrine or acetanilide and are rarely employed.

Salts and Derivatives of Quinoline.—QUINOLINÆ HYDROCHLORIDUM.—*Chinolinum Hydrochloricum. Quinoline Hydrochloride*, E.; *Chinolinchlorhydrat, Salzsaures Chinolin*, G. $C_9H_7N.HCl$.—A difficultly crystallizable colorless mass, melting at 94° C. (201.2° F.), sublimable without decomposition, soluble in water, alcohol, and chloroform, and has a sharp pungent taste.

QUINOLINÆ TARTRAS.—*Chinolinum Tartaricum. Quinoline Tartrate*, E.; *Chinolintartrat, Weinsaures Chinolin*, G. $3(C_9H_7N).4(C_4H_6O_6)$.—It is prepared by neutralizing quinoline with a slight excess of tartaric acid and recrystallizing the salt from hot alcohol, and occurs commercially as colorless, shining, needle-shaped crystals, soluble in about 75 parts (150 parts, Allen) of alcohol, 80 parts of cold water, 350 parts of ether, and melting at 125° C. (257° F.). Antipyretic and antiseptic. Dose, 5 to 15 grains (0.30–1 Gm.).

QUINOLINÆ SALICYLAS.—*Chinolinum Salicylicum. Quinoline Salicylate*, E.; *Chinolinsalicylat*, G.—A white crystalline powder, soluble in 80 parts of water, and readily soluble in alcohol, amyl alcohol, ether, chloroform, benzene, fixed and volatile oils, and glycerin. Used as the tartrate and in the same dose.

QUINOLINE SULPHOCYANATE (or RHODANATE).—A colorless to yellowish crystalline powder, difficultly soluble in cold water and ether, but readily soluble in hot water and alcohol, and melting at 137° to 138° C. (278.6°–280° F.).

QUINOLINE BISMUTH SULPHOCYANATE (or RHODANATE).—A coarse-grained reddish-yellow powder, insoluble in water, alcohol, and ether, and melts at 70° C. (158° F.).

ACETO-ORTHO-AMIDO-QUINOLINE, $C_9H_6N(NHCH_3CO)$, is an anologue of acetanilide, and occurs as colorless crystals, melting at 102.5° C. (216.5° F.).

DIAPHTHERIN.—*Oxyquinaseptol.*—Obtained by introducing into oxyquinoline phenolsulphonate a second molecule of oxyquinoline. A yellowish crystalline powder, very soluble in water, difficultly soluble in cold but readily in hot alcohol, and which melts at 85° C. (185° F.). Its aqueous solution is yellowish in color and colored bluish green on the addition

of ferric chloride, lead acetate, and barium chloride. In the aqueous solution, which is yellowish ferric chloride, addition of ferric chloride produces a bluish-green color, and lead acetate and barium chloride, yellow precipitates. Diaphtherin is used as an antiseptic in from $\frac{1}{2}$ to 1 per cent. solutions. It attacks surgical instruments.

DIAPHTHOL.—*Quinaseptol, Chinaseptol, Ortho-oxyquinoline-meta-sulphonic Acid.* $C_9H_5(OH)(SO_3H)N$.—It forms yellowish-colored crystals which are difficultly soluble in cold water, soluble in about 35 parts of hot water, and melt at 295° C. (563° F.). The aqueous solution is yellow colored, gives no precipitate with barium chloride (distinction from diaphtherin), but is precipitated bright yellow by lead acetate, and colored bluish green by ferric chloride. The properties of diaphthol are similar to those of diaphtherin.

KAIRINE.—*Ethyl Kairine, Kairine A, Oxyquinoline-ethyltetrahydride hydrochloride.* $C_9H_{10}(C_2H_5)NO.HCl$.—Kairine occurs as a grayish-white crystalline powder, having a bitter salty taste, and readily soluble in 6 parts of water and in 20 parts of alcohol. Potassium bichromate, added to the aqueous solution, develops a series of colors ranging from violet blue to purple. Ferric chloride similarly causes a violet coloration, rapidly changing to brown and precipitating. Antipyretic. Little used. Dose, 5 to 10 grains (0.30–0.60 Gm.).

KAIROLINE, A AND M.—*Quinoline-ethylhydride* (A) and *Quinoline-methylhydride* (M).—These compounds are respectively the acid sulphates of the ethyl and methyl hydrides of quinoline, and differ from kairine in not containing oxygen.

LORETIN.—*Meta-iodo-ortho-oxyquinoline-ana-sulphonic Acid.* $C_9H_4IN.OH.SO_3H$.—It forms bright yellow, odorless, stable crystals, which are but sparingly soluble in cold or hot water, and insoluble in ether and oils, melt at 270° C. (518° F.), and form neutral soluble salts with sodium, potassium, ammonium, and magnesium, yielding orange-yellow solutions. Loretin is used as a substitute for iodoform in powder, 5 to 10 per cent. ointments, or $\frac{1}{10}$ to $\frac{1}{5}$ per cent. solutions in water.

ANALGEN.—*Ortho-ethoxy-ana-mono-benzoyl-amido-quinoline, Benzanalgene, Quinalgine, Laboridin.* $C_{18}H_{16}N_2O_2$.—It forms colorless, tasteless crystals, which are insoluble in water, soluble in alcohol, and melt at 208° C. (406.4° F.). The name was formerly applied to the acetyl derivative. Analgen is used as an antineuralgic in doses of from 5 to 15 grains (0.30–1 Gm.).

QUINOSOL.—*Chinosolum, Oxy-quinoline-potassium-sulphate.* $C_9H_6N.OSO_3K + H_2O$.—It forms yellow crystals, having an astringent and aromatic taste, are readily soluble in water, give insoluble precipitates with barium chloride, lead acetate, and mercuric chloride, and a bluish-green solution when ferric chloride is added to the aqueous solution.

THALLINE SULPHATE. $2C_9H_{10}N(OCH_3).H_2SO_4 + 2H_2O$.—The base thalline, which is the methyl ether of tetrahydro-paraoxyquinoline, and its salts were discovered by Skraup in 1884, and is prepared from paraquinanisol by treatment with tin and hydrochloric acid. The last-named compound is an oily base, and is obtained by heating to about 145° C. (293° F.) a mixture of paramidoanisol, paranitranisol, glycerin, and sulphuric acid. The base thalline forms thick white prisms, which are freely soluble in alcohol, ether, and benzene, but dissolve sparingly in benzin and water. The sulphate, which has become known by the name of the base, thalline, is formed by dissolving the latter in dilute sulphuric acid and crystallizing or granulating.

Thalline sulphate is usually seen in the form of a white or whitish granular crystalline powder, which is permanent in the air, and has a slight anise-like odor and a nauseous, bitter, saline, and pungent taste, becoming more agreeable and aromatic in dilute solutions. The salt is freely soluble in hot water, sparingly soluble in chloroform and ether, and requires for solution 7 parts of cold water and 100 parts of alcohol, the solutions becoming darker on exposure to light. A solution of the salt in 10,000 parts of water acquires an emerald-green color on the addition of a little ferric chloride or other oxidizing agent, the color being not altered by sulphuric acid, but changed to purplish, reddish, or yellow by reducing agents. The solution of thalline sulphate is colored deep red on being heated with fuming nitric acid; it is not affected by tannic acid or mercuric chloride, but yields a yellow precipitate with picric acid, and alkalies separate from it the base in oily drops, becoming crystalline and having a cumarin-like odor. Thalline sulphate was official in the German Pharmacopœia of 1890, but was dropped at the last revision.

R.

RADIUM.—Radium.

Radium, Fr., G.

Symbol, Ra. Atomic weight, 223.3. Valence, 2.

History.—The metal radium is not known in the free state, but only by its salts, which were discovered in 1898 by Madame Sklodowska Curie, a Polish lady, assisted by her husband, Prof. Pierre Curie, of the École Polytechnique, at Paris. Radium is one of the most interesting and at the same time most puzzling discoveries of science, and it is occupying the attention of the most eminent minds in the field of physics and chemistry. Great discoveries are often the climax of a number of antecedent events, and this is true of radium. A brief account of the discoveries which led to the finding of radium may be interesting. On November 8, 1895, Prof. Wilhelm Konrad Roentgen, of Würzburg, Germany, accidentally discovered a peculiar kind of radiation, which is known as Roentgen or *x*-rays. When electric sparks are passed between the poles of a highly exhausted (Crookes') tube, a faint radiation in straight lines emanates from the cathode, known as cathode rays, and consisting of a stream of ultra-minute negatively charged particles. Where these cathode rays impinge on the walls of the glass tube, a brilliant golden-green fluorescence is produced, and passing out from the walls of the tube is a new kind of rays, the Roentgen, or *x*-rays, invisible to the eye, but made manifest by their effects. They proceed in straight lines, are not easily deflected by a magnet, cause many substances to become luminescent, pass through many objects which are opaque to ordinary light waves, affect photographic plates, produce physiological effects in living tissues, and change insulating media, such as air, paraffin, etc., into a conductor when they pass through them.

According to the now universally accepted theory, *x*-rays are considered to be electromagnetic waves.

It was thought that, inasmuch as Crookes' tubes emitting *x*-rays are fluorescent, bodies possessing the property of fluorescence might also give out *x*-rays. The salts of the metal uranium are noted for their fluorescence after exposure to sunlight, and they were found to affect a sensitive plate through a covering of black paper, which is impervious to ordinary light. On one occasion, in 1896, Prof. Henri Becquerel, the eminent chemist and physicist of Paris, placed some double sulphate of uranium and potassium on a covered photographic plate, but at that moment the weather became stormy, so that he could not expose the uranium salt to sunlight in order to render it fluorescent. The plate with the salt was placed in a drawer and left there for several days. Becquerel had the happy thought of developing the plate to see if anything had occurred in the dark, and, to his surprise, found the plate affected, and this without any fluorescence in the uranium salt. This led to the discovery of the remarkable radiations now known by the name of *Becquerel rays*. Becquerel also observed that uranium metal far surpassed any of its compounds in this property of emitting rays, which, though invisible, have the power of affecting a plate and of passing through opaque substances. Any substance which, like uranium, emits such invisible rays, is now said to be *radio-active*.

Among the workers who were attracted by Becquerel's discovery, the most noted is Madame Curie. She was soon led to suspect that *pitchblende*, or *uraninite*, a very complex mineral which is practically the source of all uranium salts, contained something that was far more radio-active than uranium or its salts. She and her husband commenced a most careful search for it, and discovered a substance associated with bismuth, which it resembled very much chemically, and which was named *Polonium*, in honor of her native land, Poland. In the same year, 1898, they discovered a second substance in pitchblende, associated with barium, which it resembled very closely, and which they called *Radium*. It would be out of place here to give the details of the method of extraction of radium, which is a most tedious operation, and may be found in *Chemical News*, 1903, pp. 134 and 145, which contains a translation of Madam Curie's thesis for the doctorate degree. Some idea of the enormous difficulty involved is learned from the fact that it takes 5000 tons of uranium residues (left after extraction of the uranium compounds) to produce 2.2 pounds of the radium salt, and the cost is $2000 per ton of

residue. One ton of pitchblende yields about 0.1 Gm. of radium salt. Chemically pure radium salt is enormously expensive, and perhaps less than 1 Gm. is in existence. The specimens in the market are more or less impure and of varying degrees of activity. Nearly pure radium salt costs about $6000 a gramme.

Properties.—Radium belongs to the alkaline-earth group of metals. The metal itself has not been isolated because of the scarcity of its compounds and of the fact that it would change rapidly by oxidation. All of its properties are learned through its compounds, which are very similar to those of barium in color, solubility, etc. The most remarkable property of radium is its strong radio-activity, by which it affects photographic plates through various opaque substances, makes gases conductors of electricity, causes fluorescence in various substances, discharges electrified bodies, and causes remarkable changes in living matter. Its radio-activity is 100,000 times stronger than that of uranium, taken as unity. The measuring of the activity is done by delicate electrical devices which are far more sensitive than the spectroscope. Radium salts are self-luminous, and this property increases with the purity. They also emit heat constantly—thus a flask containing 0.7 Gm. of radium bromide had a temperature of 3° C. higher than the surrounding air—the heat evolved is sufficient to melt more than an equal weight of ice every hour. Radium rays reduce silver salts, mercuric chloride, etc., transform white into red phosphorus in 24 hours, color glass, porcelain, paper, rock salt, just as cathode rays do, and cause a sensation of light when brought near the temples, or to the closed eyes. Substances placed near radium salts become themselves radio-active, and this induced activity lasts for some time. When the skin is exposed too long to radium rays, serious burns are produced, not at once, but after a considerable time, which are difficult to heal. Such a burn on the body of Prof. Becquerel required fifty-three days to heal. A few milligrams of a radium salt introduced beneath the skin of a mouse, near the vertebral column, produced death by paralysis in 3 hours. Rabbits and guinea-pigs are killed by exposure to the rays, and Henry Crookes (*Chemical News*, 1903, p. 306) killed bacterial cultures by exposing them to $\frac{1}{6}$ grain (10 Mgm.) of radium bromide through a mica screen at one inch from the plates (B. liquefaciens, B. coli communis, B. prodigiosus, etc.).

Nature of Radium Rays.—The effects produced by radium salts are due to the rays constantly sent forth. Prof. Ernest Rutherford, of Canada, an eminent authority, describes them thus: There are three kinds, α-, β-, and γ-rays. The β-rays have a marked power of penetration and of exciting phosphorescence in a large number of substances, such as barium platinocyanide, zinc sulphide, etc. They are readily deflected by a magnet, and are of the same character as cathode rays, consisting of streams of negatively charged "corpuscles" or "electrons," moving with enormous velocity and having a mass about one-thousandth-part of the hydrogen atom. The γ-rays appear to be a very penetrating kind of Roentgen rays, produced at the moment of sudden expulsion of the β-rays. They can penetrate a foot-thickness of iron. The α-rays have a relatively slight penetrating power, being completely absorbed by a few centimeters of air or a sheet of paper. They are not easily deflected by a magnet, and consist of streams of particles about twice as heavy as the hydrogen atom and positively charged, and moving with great velocity. It is thought that the self-heating of a radium salt is due to the bombardment by the α-rays in the mass of the salt.

The interpretation of these rays is that the radium atoms are very complex systems of smaller charged parts in unstable equilibrium. These complex atoms suffer spontaneous disintegration, which accounts for the material nature of the radiations, and for the fact that radium is constantly manufacturing from itself a radio-active substance or "emanation" quite distinct in properties from the parent element. This emanation possesses all the properties of a gas. It can be conducted away from the radium and condensed by extreme cold. Two other elements, thorium and uranium, both radio-active, also give off an emanation. The emanations finally lose their radio-activity and become transformed into a different substance. In 1903 Ramsay and Soddy found that radium emanations ultimately produced helium gas. This may account for the fact that helium is always found in radio-active substances.

The supposed complex nature of the atoms of the radio-active elements is apparently a blow at the atomic theory of modern chemistry, which holds that the atom of hydrogen is the smallest particle of matter that exists, and that atoms are indivisible. But the two views become reconciled if it is assumed that in the ordinary elements the mass of

particles making up the atom have reached a state of stable equilibrium, which cannot be upset by the chemical forces known at present, so that the complex atom behaves like a single particle—that is, constitutes the atom of the Dalton atomic theory. This explanation makes necessary the further assumption that all "elements" are complex, and leads to the idea of a primary substance or protyle, from which all elements are built up, a theory by no means new to the science of chemistry.

Action and Uses.—In medicine radium is employed chiefly for therapeutic purposes, although it has been employed to a limited extent for diagnostic uses. Up to the present time it has produced the best results when applied in such diseases as lupus, or cutaneous tuberculosis, and for epithelioma of a superficial nature. The sulphide of radium is diluted with chloride of barium. This is placed in a small rubber bag or disc, and this, in turn, is fastened upon the affected part for whatever time the physician thinks it is necessary to produce the results which he is seeking. In other instances the salt of radium is placed in a small cylinder, the end of which is held in close proximity, or directly against, the affected part. One of the difficulties in employing radium in this manner at the present time is that it is exceedingly expensive, and as no two samples are of the same strength, the activity of each is to be tested before it can be freely used, since by this means only can the physician gain a true conception of its power. As a summary of these remarks it may be stated that the therapeutic effects of radium are very closely allied to the effects produced by the *x*-ray in the same diseases. Indeed, in some cases the *x*-rays may be applied under the direct observation of the physician, and the patient may, at intervals, subject the growth to the action of a radium container, since in this way the effects of the ordinary *x*-rays may be increased.

RANUNCULACEÆ.—The Buttercup Family.

The Buttercup family is credited with 27 genera and about 1000 species, growing mostly in cold or temperate regions. Its useful properties pertain mostly to medicine and to ornamentation, it supplying many of the most valued of cultivated flowers—clematis, aconite, larkspur, columbine, peony, hellebore, anemone, buttercup, etc. The drugs of the family can be roughly grouped into 3 divisions: (*a*) bitter and astringent tonics of the HYDRASTIS class, including *Coptis* and *Xanthorrhiza*, considered below; (*b*) those affecting the circulation, like ACONITE, ADONIS, HELLEBORE, and PULSATILLA, separately considered, and *Actæa*, *Pæonia*, *Hepatica*, and *Clematis*, here described; (*c*) local irritants, like STAPHISAGRIA and RANUNCULUS.
